#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 04d_tensor_gammas.ipynb
#     python -m nbconvert --execute --inplace 04d_tensor_gammas.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or for a file in
#   Revision/algebra/reports: the notebook reads these Revision record files of the
#   repository; they are part of every complete clone. Run git status in the repository
#   folder: if it reports them as deleted, restore them with the command below and run
#   the notebook again.
#     git checkout HEAD Revision/algebra
#

## 3. The words used in this notebook

- **Matrix, product, identity, transpose**: a matrix is a rectangular table of
```

```
  numbers, $M_{ij}$ its entry in row $i$ and column $j$ (counted from 0 here);
  $(AB)_{ij} = \sum_k A_{ik}B_{kj}$, written ‘A @ B‘ in Python; $I_n$ is the
  $n \times n$ identity; the transpose has $(M^T)_{ij} = M_{ji}$, and
  $(AB)^T = B^T A^T$. $M$ is symmetric if $M^T = M$ and antisymmetric if
  $M^T = -M$.
- **Anticommute**: $AB = -BA$. **Clifford relation**: $\gamma^a\gamma^b +
  \gamma^b\gamma^a = 2\eta^{ab} I_{16}$: each gamma squares to $+I_{16}$
  (space-like direction) or $-I_{16}$ (time-like direction), and two different
  gammas anticommute.
- **Product of a set of directions** $\gamma_A$: for a set $A$ of directions, the
  product of their gammas in increasing order, for example
  $\gamma_{\{x_2, x_5\}} = \gamma^{(x_2)}\gamma^{(x_5)}$; $\gamma_{\{\}} = I_{16}$.
  There are $2^8 = 256$ sets, so 256 products; they are a *basis* of all real
  $16 \times 16$ matrices when every such matrix is exactly one combination
  $\sum_A c_A\gamma_A$.
- **Kronecker product** (or tensor product) $A \otimes B$ of a $2 \times 2$ matrix $A$
  and an $m \times m$ matrix $B$: the $2m \times 2m$ matrix made of four blocks, the
  block in position $(i, j)$ being $A_{ij} B$. In indices,
  $(A \otimes B)_{im + k,\; jm + l} = A_{ij} B_{kl}$. numpy writes it ‘np.kron(A, B)‘.
- **Slot**: in $M_1 \otimes M_2 \otimes M_3 \otimes M_4$ (four $2 \times 2$
  matrices, a $16 \times 16$ matrix) the position of a factor: $M_1$ stands in slot 1,
  ..., $M_4$ in slot 4.
- **Bits**: the 16 components are numbered $j = 8b_1 + 4b_2 + 2b_3 + b_4$ with four
  binary digits (bits) $b_1, b_2, b_3, b_4$, each 0 or 1, one per slot; for example
  $j = 5$ has the bits 0101.
- **Signed permutation matrix**: exactly one nonzero entry, $+1$ or $-1$, in every row
  and every column. It renumbers the components of a column and flips some signs.
  It is **orthogonal**: $M^T M = I$, so $M^{-1} = M^T$.
- **Change of basis**: two sets of matrices are related by a change of basis when an
  invertible matrix $Q$ gives $\gamma^a = Q\,\hat\gamma^a Q^{-1}$ for every $a$.
  Writing the column $\Psi = Q\chi$ then turns every equation written with one set
  into the same equation written with the other.
- **Intertwiner**: a matrix $X$ with $\gamma^a X = X \hat\gamma^a$ for every $a$.
- **Commute with all gammas**: $X\gamma^a = \gamma^a X$ for all eight $a$.
- **Solution space**: the set of all solutions $X$ of a list of linear equations
  without constant terms; its **dimension** is the number of free parameters.
  For 256 unknowns it is $256$ minus the **rank** of the equations (the largest number
  of independent ones). sympy computes ranks exactly with fractions.
- **Eigenvalue, eigenvector, multiplicity**: $Mv = \lambda v$ with $v \neq 0$; the
  multiplicity of $\lambda$ is the number of independent eigenvectors that belong to it.
- **Chirality product**: the product
  $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)} \cdots \gamma^{(x_7)}$ of all
  eight gammas, in this order (the author’s order); the Revision record calls it the
  chirality. Here it is only a product of eight matrices.
- **Diagonal matrix**: all entries off the diagonal are 0.
```

```
## 4. The physical and mathematical situation

The author’s space-time has the coordinates $x_0$ (the hidden direction),
$x_1, x_2, x_3$ (3-space, inflating), $x_4$ (the time) and $x_5, x_6, x_7$ (three
extra times, which deflate exponentially: scale factor
```

$b_4^{1/2}e^{-a_4}\sin^{1/6} z$). In a local
frame the signs are $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$: four
space-like and four time-like directions. The gamma matrices are constant matrices
of the frame; the inflation and the deflation enter the field equation through the
frame factors, never through the gammas. So the question of this notebook is pure
algebra: how many essentially different real 16×16 solutions of the
Clifford relation are there?

Three 2×2 matrices.
$P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$,
$N = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$,
$G = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. They are real; P and G are
symmetric, N is antisymmetric; $P^2 = G^2 = I_2$ and $N^2 = -I_2$; and any two
of them anticommute: $PN = -G = -NP$, $PG = -N = -GP$, $NG = -P = -GN$ (each is
one 2×2 multiplication; for example
$PG = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = -N$).

The mixed-product rule. $(A \otimes B)(C \otimes D) = (AC) \otimes (BD)$. Line
by line: the entry in row $im + k$, column $jm + l$ of the left side is
$\sum_{r,s} (A \otimes B)_{im+k,\, rm+s} (C \otimes D)_{rm+s,\, jm+l}$ (the product
rule, summing over all columns $rm + s$ of the first factor); by the index formula
this is $\sum_{r,s} A_{ir}B_{ks}C_{rj}D_{sl}$; the sum splits into
$(\sum_r A_{ir}C_{rj})(\sum_s B_{ks}D_{sl}) = (AC)_{ij}(BD)_{kl}$, which is the entry
of $(AC) \otimes (BD)$. With four slots the rule works slot by slot. Also
$(A \otimes B)^T = A^T \otimes B^T$.

The recipe. For a slot $k = 1, 2, 3, 4$ and $M = P$ or N put G into the
slots before k, M into slot k and I_2 into the slots after k. Every
space-like direction gets a P and every time-like direction an N, and each slot
is shared by one space-like and one time-like direction. This notebook uses the
pairs (x1, x6) in slot 1, (x2, x5) in slot 2, (x3, x4) in slot 3 and (x0, x7) in
slot 4; for example
$\hat\gamma^{(x_1)} = P \otimes I_2 \otimes I_2 \otimes I_2$,
$\hat\gamma^{(x_5)} = G \otimes N \otimes I_2 \otimes I_2$ and
$\hat\gamma^{(x_0)} = G \otimes G \otimes G \otimes P$. (Section 12 of this notebook,
below, explains why these pairs are the ones that match the author's matrices.)

Why the recipe satisfies the Clifford relation (by the mixed-product rule, every
product is computed slot by slot):

1. Squares: every slot is squared; $G^2 = I_2^2 = P^2 = I_2$ and $N^2 = -I_2$, so a
   matrix with P squares to $+I_{16}$ (space-like) and one with N to $-I_{16}$
   (time-like).
2. The two matrices of the same slot k: their two products agree in every slot
   except slot k, which holds PN in one order and $NP = -PN$ in the other; so
   they anticommute.
3. Two matrices of different slots $k < l$: compare the two orders slot by slot.
   Before k both have G ($GG = GG$); in slot k the first has P or N and the
   second G, which anticommute (one factor -1); between k and l the first has
   I_2 and the second G (they commute); in slot l the first has I_2 (it
   commutes with everything); after l both have I_2. Exactly one factor -1:
   they anticommute.

The change of basis, line by line. Let γ_A and $\hat\gamma_A$ be the

products of the gammas of a set A of directions in increasing order, for all 256 sets A (with $\gamma_{\{\}} = I_{16}$). For any 16×16 matrix M define $S = \sum_A \gamma_A M \hat\gamma_A^T$.

1. Fix a direction b. Moving $\gamma^{(b)}$ into its place in $\gamma^{(b)}\gamma_A$ uses only the Clifford relation, so $\gamma^{(b)}\gamma_A = \epsilon\,\gamma_{A'}$ with $A' = A \triangle \{b\}$ (b added to A, or removed if it was in A) and a sign $\epsilon = \pm 1$ that depends only on b, A and η. The hat matrices satisfy the same relation, so $\hat\gamma^{(b)}\hat\gamma_A = \epsilon\,\hat\gamma_{A'}$ with the SAME sign.
2. Both sets are signed permutation matrices, hence orthogonal: $(\hat\gamma^{(b)})^{-1} = (\hat\gamma^{(b)})^T$. From step 1, $\hat\gamma_A = \epsilon\,(\hat\gamma^{(b)})^T\hat\gamma_{A'}$, and transposing, $\hat\gamma_A^T = \epsilon\,\hat\gamma_{A'}^T\hat\gamma^{(b)}$.
3. Therefore $\gamma^{(b)} S = \sum_A \epsilon\,\gamma_{A'} M\, \epsilon\,\hat\gamma_{A'}^T\hat\gamma^{(b)} = (\sum_A \gamma_{A'} M \hat\gamma_{A'}^T)\,\hat\gamma^{(b)}$, because $\epsilon^2 = 1$.
4. As A runs through all 256 sets, $A' = A \triangle \{b\}$ also runs through all 256 sets, each exactly once (doing it twice gives A back). So the sum is S again: $\gamma^{(b)} S = S\,\hat\gamma^{(b)}$ for every b. S is an intertwiner.

S is orthogonal up to a factor. Transpose $\gamma^{(b)} S = S\hat\gamma^{(b)}$: $S^T(\gamma^{(b)})^T = (\hat\gamma^{(b)})^T S^T$. Both sets have the same symmetry pattern, $(\gamma^{(b)})^T = \eta_{bb}\gamma^{(b)}$ and $(\hat\gamma^{(b)})^T = \eta_{bb}\hat\gamma^{(b)}$; dividing by $\eta_{bb} = \pm 1$ gives $S^T\gamma^{(b)} = \hat\gamma^{(b)} S^T$. Then $(S^T S)\hat\gamma^{(b)} = S^T\gamma^{(b)} S = \hat\gamma^{(b)}(S^T S)$: the matrix $S^T S$ commutes with all eight hat gammas.

Only multiples of the identity commute with all gammas. If X commutes with every $\hat\gamma^{(b)}$, it commutes with every product $\hat\gamma_A$, hence with every combination of them; the 256 products are a basis of all real 16×16 matrices (this notebook checks their exact rank, 256), so X commutes with every matrix, in particular with E_{ij}, the matrix with a single 1 in row i and column j. The entry in row k, column j of XE_{ij} is X_{ki}, and that of $E_{ij}X$ is X_{jj} if $k = i$ and 0 otherwise. So $X_{ki} = 0$ for $k \neq i$, and $X_{ii} = X_{jj}$: $X = cI_{16}$. Applied to $S^T S$: $S^T S = c\,I_{16}$, and $c > 0$ when $S \neq 0$ (c is the sum of the squares of a column of S). Then $Q = S/\sqrt{c}$ satisfies $Q^T Q = I_{16}$ and $\gamma^{(b)} = Q\,\hat\gamma^{(b)} Q^T$.

Unique up to a factor. If X is any intertwiner, then $Q\hat\gamma^{(b)}Q^T X = X\hat\gamma^{(b)}$, so $Q^T X$ commutes with every $\hat\gamma^{(b)}$ (multiply by Q^T on the left), so $Q^T X = cI_{16}$ and $X = cQ$.

What it means for the field equation. In flat 4+4 space write $\Psi = Q\chi$. Then $\gamma^{(a)}\partial_a\Psi = Q\hat\gamma^{(a)}Q^T Q\,\partial_a\chi = Q\,\hat\gamma^{(a)}\partial_a\chi$, so $\sum_a\gamma^{(a)}\partial_a\Psi = m\Psi$ becomes $Q(\sum_a\hat\gamma^{(a)}\partial_a\chi - m\chi) = 0$, and, because Q is invertible, $\sum_a\hat\gamma^{(a)}\partial_a\chi = m\chi$: the same equation in the other basis. The choice between the two sets is a choice of how to number the 16 components, not a choice of physics.

```

Text cell:

```
## 6. The Kronecker product

The next cell computes $P \otimes G$ with ‘np.kron‘ and prints it; by the index
formula it is $\begin{pmatrix} 0 \cdot G & 1 \cdot G \\ 1 \cdot G & 0 \cdot G
\end{pmatrix}$. It checks the index formula entry by entry, defines ‘kron4‘ for four
slots, and checks the mixed-product rule exactly on random whole-number matrices
(seed 12345, so every run uses the same numbers): with two slots,
$(A \otimes B)(C \otimes D) = (AC) \otimes (BD)$, and with four slots, slot by slot.
```

In [3]:

```
example = np.kron(P, G)  # the 4 x 4 matrix P (x) G
print("P (x) G =")
for row in example:
    print("    " + " ".join(f"{x:2d}" for x in row))

                 for i, j, k, l in itertools.product(range(2), repeat=4))

def kron4(m1, m2, m3, m4):
    """m1 (x) m2 (x) m3 (x) m4: a 16 x 16 matrix made of four 2 x 2 matrices."""
    return np.kron(np.kron(np.kron(m1, m2), m3), m4)

generator = np.random.default_rng(12345)  # fixed seed: the same numbers every run
a1, b1, a2, b2 = (generator.integers(-3, 4, size=(2, 2)) for _ in range(4))
two_slots = (np.kron(a1, b1) @ np.kron(a2, b2) == np.kron(a1 @ a2, b1 @ b2)).all()
first = [generator.integers(-3, 4, size=(2, 2)) for _ in range(4)]  # four slots
second = [generator.integers(-3, 4, size=(2, 2)) for _ in range(4)]
four_slots = (kron4(*first) @ kron4(*second)
              == kron4(*[f @ s for f, s in zip(first, second)])).all()
check(formula_ok and two_slots and four_slots,
      "Kronecker product: index formula and mixed-product rule (2 and 4 slots)")
```

Out [3]:

```
P (x) G =
     0  0  1  0
     0  0  0 -1
     1  0  0  0
     0 -1  0  0
PASS Kronecker product: index formula and mixed-product rule (2 and 4 slots)
```

Text cell:

```
## 7. The eight tensor-product gammas

The next cell reads the coordinate names and the signs $\eta$ from the Revision
record file ‘Revision/algebra/gammas.json‘ (and the author’s eight gammas, used from
section 9 on), and builds the eight hat gammas with the recipe. The list ‘SLOT‘
holds the slot of $x_0, \dots, x_7$: slot 1 for $x_1$ and $x_6$, slot 2 for $x_2$ and
$x_5$, slot 3 for $x_3$ and $x_4$, slot 4 for $x_0$ and $x_7$. A space-like direction
($\eta = +1$) gets P, a time-like one N. The cell prints the four factors of each
matrix.
```

In [4]:

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
```

```
COORDINATES = record["coordinates"]  # ["x0", ..., "x7"]
eta = record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1]

## 8. The Clifford relation and the 256 products

The next cell checks exactly, for the hat gammas: the Clifford relation for all 64
ordered pairs (each anticommutator is $2\eta^{ab} I_{16}$); that every hat gamma is a
signed permutation matrix; and that it has the author's symmetry pattern
$(\hat\gamma^{(x_a)})^T = \eta_{aa}\hat\gamma^{(x_a)}$ (symmetric for
$x_0, x_1, x_2, x_3$, antisymmetric for $x_4, \dots, x_7$; P, G and $I_2$ are
symmetric and N antisymmetric, so this follows from $(A \otimes B)^T = A^T \otimes
B^T$). Then it forms the 256 ordered products of BOTH sets (sets of directions in
increasing order, as `itertools.combinations` lists them) and computes the exact
rank of the 256 hat products, each written as a row of 256 numbers.
```

## 9. The chirality product in both pictures

For the hat gammas the product of all eight can be found by hand. First the product
of the two matrices of one slot $k$: slot by slot, $G \cdot G = I_2$ before $k$,
$PN = -G$ in slot $k$, and $I_2$ after $k$; so it is $-(G$ in slot $k$, $I_2$
elsewhere$)$. Second, the chirality product $\hat\Gamma$ takes the factors in the
author's order $x_0, x_1, x_2, \dots, x_7$; reordering them into the pairs
$(x_1, x_6), (x_2, x_5), (x_3, x_4), (x_0, x_7)$ exchanges neighbours that
anticommute, so it multiplies the product by the *permutation sign* of the
reordering: $+1$ if the number of *inversions* (pairs of factors whose order is
reversed) is even and $-1$ if it is odd, because each exchange of two neighbours
gives a factor $-1$ and changes the number of inversions by one.
Third, the four pair products give
$(-1)^4\, G \otimes G \otimes G \otimes G$ (each slot receives one G). Its diagonal
entry in row $j = 8b_1 + 4b_2 + 2b_3 + b_4$ is $(-1)^{b_1 + b_2 + b_3 + b_4}$,
because $G = \mathrm{diag}(+1, -1)$ contributes $-1$ for every bit equal to 1.

The next cell checks the pair products, computes the permutation sign of the
reordering, checks $\hat\Gamma = $ sign $\times\, G \otimes G \otimes G \otimes G$,
and compares with the author's chirality product
$\Gamma = \mathrm{diag}(-I_8, I_8)$, which the Revision record checked. `format(j,
"04b")` writes the number $j$ with four binary digits.

## 10. The change of basis

The next cell computes $S = \sum_A \gamma_A M \hat\gamma_A^T$ for the simplest
choices $M = E_{ij}$. The term $\gamma_A E_{ij} \hat\gamma_A^T$ has the entry
$(\gamma_A)_{ki} (\hat\gamma_A)_{lj}$ in row $k$, column $l$ (only column $i$ of
$\gamma_A$ and column $j$ of $\hat\gamma_A$ survive), so the whole sum over the 256
sets is ONE matrix product: the $16 \times 256$ table of the columns $i$ of all
$\gamma_A$ times the $256 \times 16$ table of the columns $j$ of all $\hat\gamma_A$.
The cell confirms this shortcut against the plain sum for the first nonzero $S$,
which it finds by trying $(i, j) = (0, 0), (0, 1), \dots$ in order. Then it checks,
exactly: $\gamma^{(x_a)} S = S \hat\gamma^{(x_a)}$ for all eight directions,
$S^T S = c I_{16}$, and that $Q = S/\sqrt{c}$ is a signed permutation matrix. It
```

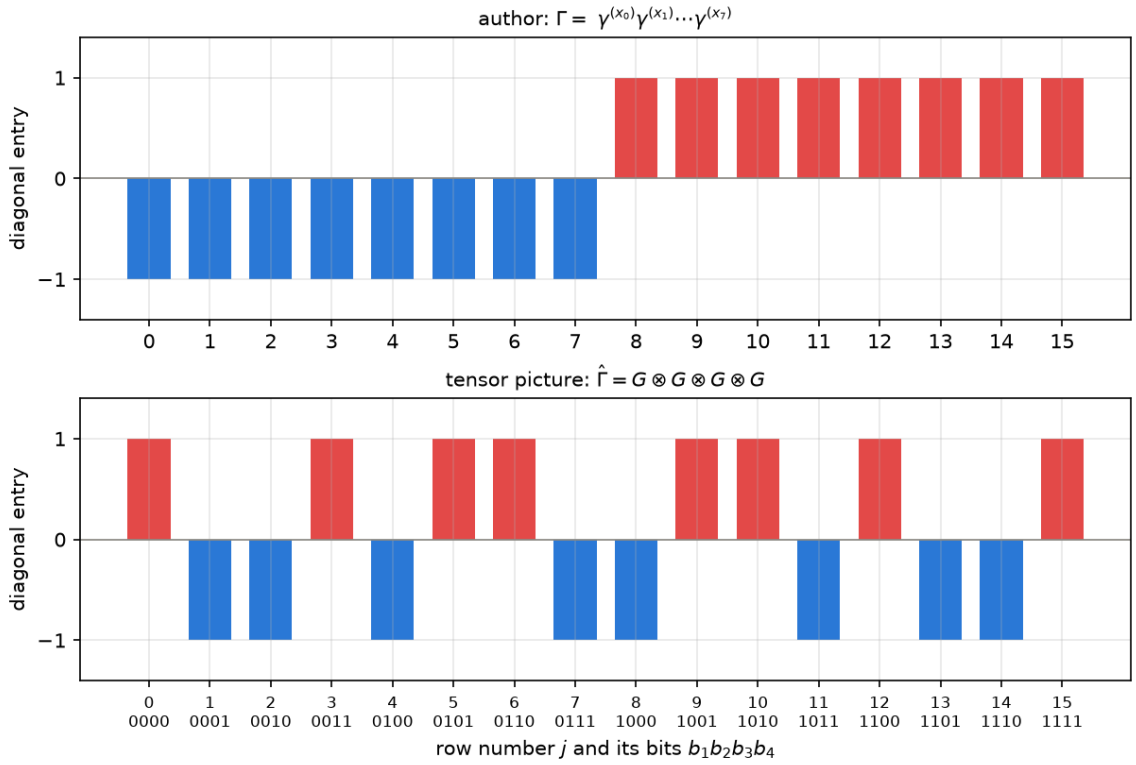

Figure 138: The chirality product in the two pictures; both are diagonal matrices, and the bars show their 16 diagonal entries (horizontal axis the row number j from 0 to 15, blue -1, red $+1$). Top: the author's Γ has -1 in rows 0 to 7 and $+1$ in rows 8 to 15. Bottom: the tensor-product $\hat{\Gamma} = G \otimes G \otimes G \otimes G$ has (-1) to the power $b_1 + b_2 + b_3 + b_4$, -1 exactly in the rows 1, 2, 4, 7, 8, 11, 13, 14 whose bits contain an odd number of ones. Both have eight entries of each sign; the change of basis of the next figure moves the eight rows with -1 to the top. (Notebook 04d, figure 3.)

```
prints $Q$ in a short code notation: for each row the column and the sign of its
single nonzero entry, so "+8" in row 0 means $(Qu)_0 = +u_8$ for every column $u$.
```

      "Q = S / sqrt(c) is a signed permutation matrix (orthogonal)")
```

Out [10]:

```
RESULT first (i, j) with a nonzero S = (0, 8)
RESULT the different entries of S = [-16, 0, 16]
RESULT c in S^T S = c I16, and its square root = (256, 16)
PASS S intertwines: gamma^a S = S hat gamma^a for all 8 a, and S^T S = c I16
rows 0 to 15 of Q: +8 +4 +2 -14 -7 +11 -13 -1 -9 -5 -3 +15 -6 +10 -12 -0
PASS Q = S / sqrt(c) is a signed permutation matrix (orthogonal)
```

Text cell:

```
The next cell checks the full statement: not only the eight gammas but all 256
products and the chirality product transform with $Q$,
$\gamma_A = Q\hat\gamma_A Q^T$ and $\Gamma = Q\hat\Gamma Q^T$. It also checks a
formula that explains which $E_{ij}$ give a nonzero $S$: for every $i, j$,
$S(E_{ij}) = 16\,Q_{ij}\,Q$. (Reason: $\sum_A \hat\gamma_A Y \hat\gamma_A^T$ commutes
with every hat gamma by the argument of the situation section, so it is a multiple
of $I_{16}$; its trace is $\sum_A \mathrm{tr}\,Y = 256\,\mathrm{tr}\,Y$, so it is
$16\,\mathrm{tr}(Y) I_{16}$; with $\gamma_A = Q\hat\gamma_A Q^T$ and $Y = Q^T E_{ij}$
this gives $S(E_{ij}) = Q \cdot 16\,\mathrm{tr}(Q^T E_{ij}) = 16\,Q_{ij}\,Q$.) So $S$
is nonzero exactly for the 16 positions $(i, j)$ where $Q$ has its nonzero entries,
and the first of them is the one found above.
```

## 11. Only one change of basis

The situation section proved that every intertwiner is a multiple of $Q$. The next
cell checks it directly. The equations $\gamma^{(x_a)} X - X\hat\gamma^{(x_a)} = 0$
for the 256 entries of $X$ (read row by row: entry $(k, l)$ is unknown number
$16k + l$) form a system of $8 \times 256 = 2048$ equations; with this numbering
$LX$ becomes $(L \otimes I_{16})$ times the list of unknowns and $XR$ becomes
$(I_{16} \otimes R^T)$ times it (write out both products entry by entry). The cell
computes the exact rank of the system: 255, so the solutions form a space of
dimension $256 - 255 = 1$, the multiples of $Q$. It does the same for the
equations $\gamma^{(x_a)} X - X\gamma^{(x_a)} = 0$, the matrices that commute with
all eight of the author's gammas: dimension 1 again (the multiples of $I_{16}$), the
number that the Revision record found with two independent programs.
```

In [13]:

```
def intertwiner_system(left, right):
    """The 2048 x 256 matrix of the equations left[a] X - X right[a] = 0, a = 1..8,
    for the 256 entries of X read row by row."""
    return np.vstack([np.kron(left[a], I16) - np.kron(I16, right[a].T)
                      for a in range(8)])

system = intertwiner_system(gamma, hat)  # the author's gammas and the hat gammas
commutant = intertwiner_system(gamma, gamma)  # the author's gammas on both sides
rank_system, rank_commutant = exact_rank(system.tolist()), exact_rank(
    commutant.tolist())
report("exact ranks of the two systems (2048 equations, 256 unknowns)",
       (rank_system, rank_commutant))
```

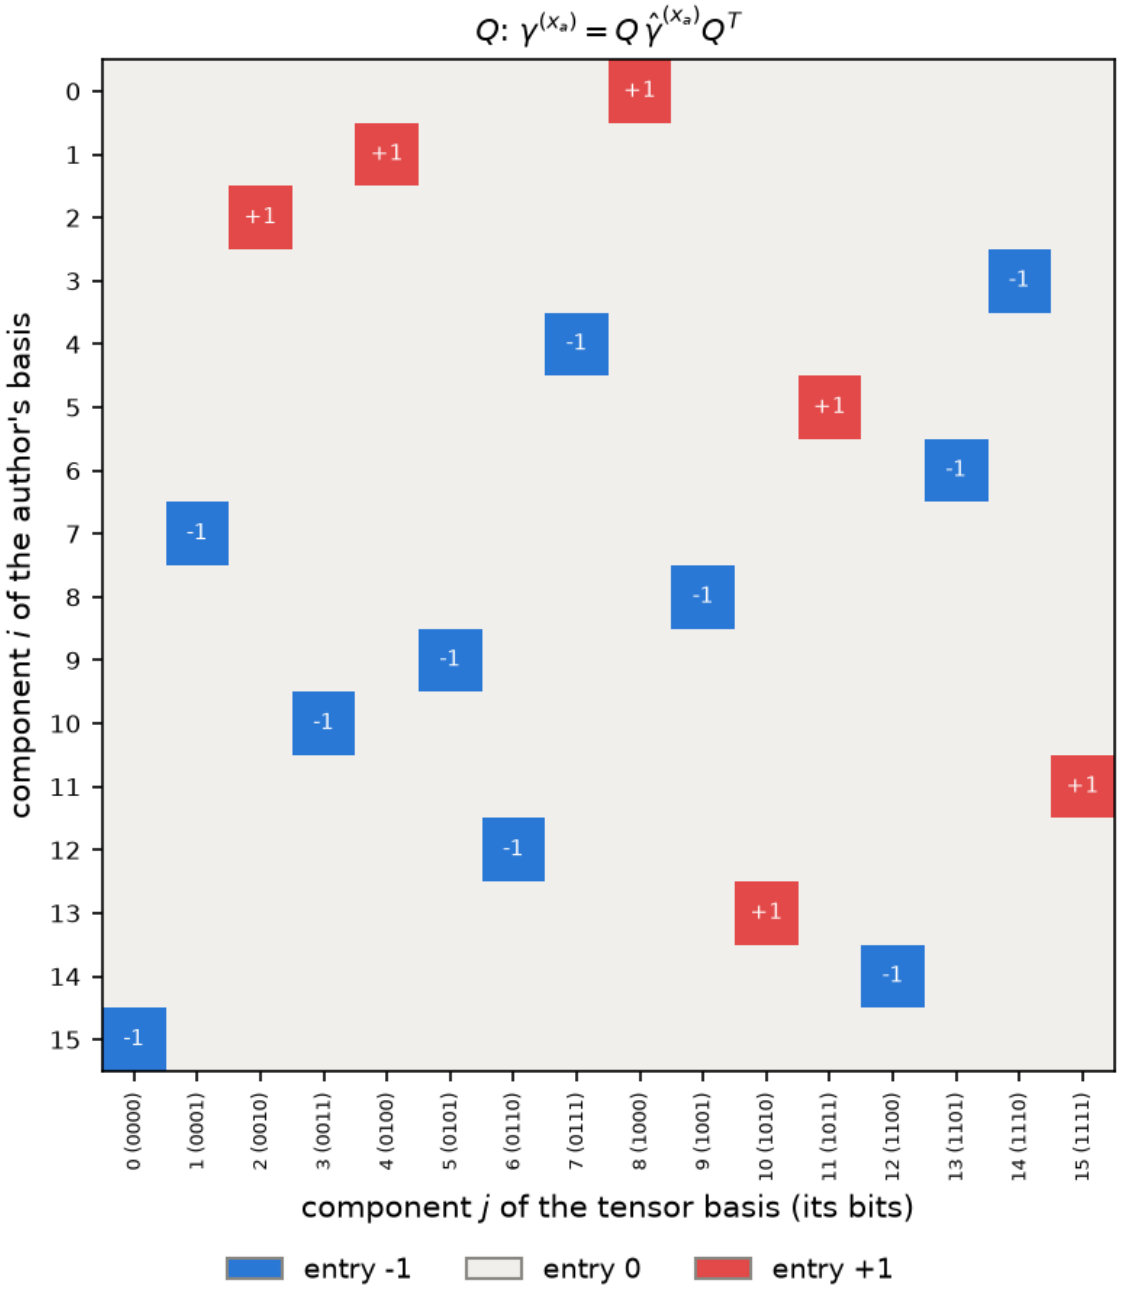

Figure 139: The change of basis Q from the tensor-product gammas to the author's gammas, $\gamma^{(x_a)} = Q\hat{\gamma}^{(x_a)}Q^T$ for all eight directions (rows: the author's components 0 to 15; columns: the tensor components 0 to 15 with their bits; blue -1, red $+1$). Q is a signed permutation: every row and column holds one entry ± 1, so the author's matrices are the tensor-product matrices with the 16 components renumbered and some signs flipped. The first eight rows pick the eight tensor components with an odd number of ones in their bits, the rows where $\hat{\Gamma} = -1$. (Notebook 04d, figure 4.)

```
**How strongly the equations reject every other matrix.** Square the left-hand
sides and add them up: for a matrix $X$ (as a list $v$ of 256 numbers) the sum of
the squares of all 2048 equations is $v^T K v$ with the $256 \times 256$ matrix
$K = A^T A$, where $A$ is the system. $K$ has a complete set of exact eigenvectors:
the matrices $X_B = Q\hat\gamma_B$ for the 256 sets $B$. Line by line:

1. Write $L_a(X) = \gamma^{(a)} X - X\hat\gamma^{(a)}$ for the left-hand side of
   equation block $a$; then $A$ is the stack of the eight blocks $L_a$, and
   $K = \sum_a L_a^T L_a$ (a matrix product of a stack with its transpose adds up
   the products of the blocks).
2. The transpose of the block $L_a$ is the map
   $Y \to (\gamma^{(a)})^T Y - Y(\hat\gamma^{(a)})^T$ (the rows of the system become
   its columns). Both sets have $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$ and
   $(\hat\gamma^{(a)})^T = \eta_{aa}\hat\gamma^{(a)}$, so $L_a^T = \eta_{aa} L_a$
   and $K = \sum_a \eta_{aa} L_a L_a$.
3. $L_a(X_B) = Q\hat\gamma^{(a)}Q^T Q\hat\gamma_B - Q\hat\gamma_B\hat\gamma^{(a)}
   = Q(\hat\gamma^{(a)}\hat\gamma_B - \hat\gamma_B\hat\gamma^{(a)})$ (insert
   $\gamma^{(a)} = Q\hat\gamma^{(a)}Q^T$ and $Q^T Q = I_{16}$). By the rule for passing
   one gamma through a product of $k$ gammas this is 0 when $\hat\gamma^{(a)}$
   commutes with $\hat\gamma_B$, and $2Q\hat\gamma^{(a)}\hat\gamma_B$ when it
   anticommutes.
4. In the anticommuting case apply $L_a$ once more: $L_a(2Q\hat\gamma^{(a)}
   \hat\gamma_B) = 2Q(\hat\gamma^{(a)}\hat\gamma^{(a)}\hat\gamma_B -
   \hat\gamma^{(a)}\hat\gamma_B\hat\gamma^{(a)}) = 2Q(\eta_{aa}\hat\gamma_B +
   \eta_{aa}\hat\gamma_B) = 4\eta_{aa}X_B$ (the square is $\eta_{aa}$, and
   $\hat\gamma_B\hat\gamma^{(a)} = -\hat\gamma^{(a)}\hat\gamma_B$). Multiplied by
   the $\eta_{aa}$ of step 2 it gives $4X_B$, because $\eta_{aa}^2 = 1$.
5. Adding over $a$: $K v_B = 4\,n_B\,v_B$, where $n_B$ is the number of directions
```

```
   whose gamma anticommutes with $\hat\gamma_B$. These are the $k$ directions in
   $B$ for an even $k$, and the $8 - k$ directions outside $B$ for an odd $k$.

So the eigenvalues are $0, 4, 8, \dots, 32$ with the multiplicities
$\binom{8}{0}, \binom{8}{1}, \dots, \binom{8}{8}$, and the eigenvalue 0 belongs only
to $B = \{\}$, that is to $Q$. The next cell checks $K v_B = 4 n_B v_B$ exactly for
all 256 sets, counts the multiplicities, and confirms them with numpy's
floating-point eigenvalues (rounded to whole numbers).
```

## 12. Another way to fill the slots

Any assignment of the eight directions to the slots works for the Clifford
relation, as long as every slot gets one P and one N. Take the simpler-looking one:
$x_1, x_2, x_3$ in slots 1, 2, 3 with P, $x_4, x_5, x_6$ in slots 1, 2, 3 with N,
and $x_0$ (P) and $x_7$ (N) in slot 4. The pairs are now (x1, x4), (x2, x5),
(x3, x6) and (x0, x7). By the theorem a change of basis must exist again. Is it a
signed permutation?

A signed permutation $Q$ turns a diagonal matrix $D$ into a diagonal matrix
$QDQ^T$ (it only renumbers the diagonal entries and multiplies each by
$(\pm 1)^2 = 1$). So if $\gamma_A = Q\hat\gamma_A Q^T$ with a signed permutation $Q$,
then $\gamma_A$ is diagonal exactly when $\hat\gamma_A$ is: the two sets must have
their diagonal products for the SAME sets $A$. The next cell lists these sets. For
the author's gammas they are the 16 sets made of whole pairs (x1, x6), (x2, x5),
(x3, x4), (x0, x7) (the products of the two matrices of one pair are diagonal, as
section 9 showed for the hat gammas); the first assignment has the same pairs, the
second has different ones. The cell then builds the second set, checks its Clifford
relation, and computes its change of basis $S_2$ with the same formula: $S_2^T S_2 =
128\,I_{16}$, and every row of $S_2$ has two nonzero entries $\pm 8$, so
$Q_2 = S_2/\sqrt{128}$ has the entries $\pm 8/\sqrt{128} = \pm 1/\sqrt2$: an
orthogonal matrix that mixes the components in pairs, not a signed permutation.
```

In [16]:

```

ALL 18 CHECKS PASSED (notebook 04d)
```

Text cell:

```
## 14. What this notebook showed

- PROVED (exact integer arithmetic): Kronecker products of the three $2 \times 2$
  matrices P, N and G give eight real $16 \times 16$ signed permutation matrices
  $\hat\gamma^{(x_a)}$ that satisfy the Clifford relation of the author's 4+4
  space-time, $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$, with the
  author's symmetry pattern; their 256 products are a basis of all real
  $16 \times 16$ matrices (exact rank 256).
- PROVED: the chirality product of the tensor set is
  $G \otimes G \otimes G \otimes G$, diagonal with the sign $(-1)^{b_1 + b_2 + b_3 +
  b_4}$; the author's is $\mathrm{diag}(-I_8, I_8)$ (reproduces
  `Revision/algebra/reports/wolfram-algebra.json`, check `Gamma_diag`, and
  `python-algebra.json`, check `chirality_diag`).
- PROVED: the formula $S = \sum_A \gamma_A M \hat\gamma_A^T$ produces a change of
  basis; with the pairs (x1, x6), (x2, x5), (x3, x4), (x0, x7) it is $16\,Q$ with a
  signed permutation matrix $Q$, and $\gamma_A = Q\hat\gamma_A Q^T$ for all 256
  products. The author's T16 are the tensor-product gammas with the 16 components
  renumbered and some signs flipped.
- PROVED: the change of basis is unique up to a factor (the 2048 equations have
  rank 255; the penalty matrix $K$ has the eigenvalue 0 only for $Q$), and only the
  multiples of $I_{16}$ commute with all eight of the author's gammas (reproduces
  the checks `pin_commutant_dimension_1` and `Pin44_irreducible_commutant_dim_1`).
- PROVED: with other pairs in the slots the Clifford relation still holds and a
  change of basis still exists, but it mixes the components in pairs (entries
  $\pm 1/\sqrt2$), because the diagonal products then belong to different sets of
  directions.
- ASSUMED: nothing beyond the Clifford relation. These are statements of algebra:
  every equation written with the author's gammas is the same equation written with
  the tensor-product gammas after the renumbering $\Psi = Q\chi$; the choice of
  the set is a choice of basis, not of physics. The inflation of 3-space and the
  deflation of the extra times enter the field equation through the frame factors,
  the same for both sets.
```

4.20 Line-by-line walk-through of Notebook 04d

The notebook has 18 code cells, In [1] to In [18]. As in Section 4.8, every line is quoted except two things: the set-up cell In [1], which is the set-up cell of Notebook 04a explained line by line in Section 4.8 and differs from it only as said below, and the long caption texts handed to `save_figure`, which are shortened to a line `...)` (the dots stand for the caption, the bracket closes the call); each caption is printed in full under its figure in Section 4.19.

In [1], the set-up cell. It is the set-up cell of Notebook 04a, explained line by line in Section 4.8, except for the line `NOTEBOOK_ID = "04d"` and the run instructions of Section 4.18 in its comment lines. It prints one line.

In [2], the three 2×2 matrices.

```
import itertools  # all subsets of a given size, all pairs of indices
from math import comb  # comb(n, k): the binomial coefficient "n choose k"

import numpy as np  # integer matrices; their sums and products are exact
import sympy as sp  # exact ranks, computed with fractions
```

```
from matplotlib.colors import BoundaryNorm, ListedColormap
from matplotlib.patches import Patch
from sympy.polys.matrices import DomainMatrix  # exact matrices for the rank
```

The imports, as in Notebooks 04a and 04c.

```
P = np.array([[0, 1], [1, 0]], dtype=np.int64)
N = np.array([[0, 1], [-1, 0]], dtype=np.int64)
G = np.array([[1, 0], [0, -1]], dtype=np.int64)
I2 = np.eye(2, dtype=np.int64)
for name, m in (("P", P), ("N", N), ("G", G)):
    say(f"{name} = {m.tolist()},  {name} {name} = {(m @ m).tolist()}")
```

P, N, G and I_2 as whole-number arrays; the loop prints each matrix and its square: $PP = GG = I_2$ and $NN = -I_2$.

```
squares = (P @ P == I2).all() and (G @ G == I2).all() and (N @ N == -I2).all()
triples = [(P, N, -G), (P, G, -N), (N, G, -P)]  # (A, B, the product A B)
# A B = C and B A = -C for each triple: the two matrices anticommute
products_ok = all((a @ b == c).all() and (b @ a == -c).all() for a, b, c in triples)
symmetry_ok = (P.T == P).all() and (G.T == G).all() and (N.T == -N).all()
check(squares and products_ok and symmetry_ok,
      "P^2 = G^2 = I2, N^2 = -I2, PN = -G, PG = -N, NG = -P, any two anticommute")
```

`triples` lists three triples (A, B, C) with $AB = C$; the check requires $AB = C$ and $BA = -C$ for each (so the pairs anticommute), the squares, and the symmetry of P and G and antisymmetry of N: every rule of Section 4.17.

In [3], the Kronecker product.

```
example = np.kron(P, G)  # the 4 x 4 matrix P (x) G
print("P (x) G =")
for row in example:
    print("    " + " ".join(f"{x:2d}" for x in row))
```

`np.kron(P, G)` computes $P \otimes G$ (written `P (x) G` in printed text), and the loop prints its four rows: the matrix of Section 4.17.

```
# index formula with m = 2: (A (x) B)[2i + k, 2j + l] = A[i, j] B[k, l]
formula_ok = all(example[2 * i + k, 2 * j + l] == P[i, j] * G[k, l]
                 for i, j, k, l in itertools.product(range(2), repeat=4))
```

The index formula is checked for all 16 combinations of i, j, k, l in $\{0, 1\}$.

```
def kron4(m1, m2, m3, m4):
    """m1 (x) m2 (x) m3 (x) m4: a 16 x 16 matrix made of four 2 x 2 matrices."""
    return np.kron(np.kron(np.kron(m1, m2), m3), m4)
```

`kron4` forms $m_1 \otimes m_2 \otimes m_3 \otimes m_4$, a 16×16 matrix, by three Kronecker products in a row.

```
generator = np.random.default_rng(12345)  # fixed seed: the same numbers every run
a1, b1, a2, b2 = (generator.integers(-3, 4, size=(2, 2)) for _ in range(4))
two_slots = (np.kron(a1, b1) @ np.kron(a2, b2) == np.kron(a1 @ a2, b1 @ b2)).all()
first = [generator.integers(-3, 4, size=(2, 2)) for _ in range(4)]  # four slots
second = [generator.integers(-3, 4, size=(2, 2)) for _ in range(4)]
four_slots = (kron4(*first) @ kron4(*second)
              == kron4(*[f @ s for f, s in zip(first, second)])).all()
check(formula_ok and two_slots and four_slots,
      "Kronecker product: index formula and mixed-product rule (2 and 4 slots)")
```

Random 2×2 matrices of whole numbers from -3 to 3 (fixed seed) test the mixed-product rule: with two slots, $(a_1 \otimes b_1)(a_2 \otimes b_2) = (a_1 a_2) \otimes (b_1 b_2)$; with four slots, slot by slot (`*first` hands the four matrices of the list to `kron4` as four arguments; `zip` pairs the slots of the two lists; the name `_` marks a loop variable that is not used).

In [4], the eight tensor-product gammas.

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
COORDINATES = record["coordinates"]  # ["x0", ..., "x7"]
eta = record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1]
gamma = [np.array(m, dtype=np.int64) for m in record["gamma"]]  # the author's
I16 = np.eye(16, dtype=np.int64)
SLOT = [4, 1, 2, 3, 3, 2, 1, 4]  # slots of x0..x7: (x1,x6) (x2,x5) (x3,x4) (x0,x7)
```

The coordinate names, the signs and the author's gammas are read from `gammas.json`. `SLOT` gives the slot of each direction $x_0, \ldots, x_7$: x_1 and x_6 in slot 1, x_2 and x_5 in slot 2, x_3 and x_4 in slot 3, x_0 and x_7 in slot 4; so the list is $4, 1, 2, 3, 3, 2, 1, 4$.

```
def factor_names(slot, middle):
    """The names of the four factors: G before the slot, middle in it, I after."""
    return ["G"] * (slot - 1) + [middle] + ["I"] * (4 - slot)

MATRIX_OF = {"G": G, "P": P, "N": N, "I": I2}  # name -> 2 x 2 matrix
FACTORS = [factor_names(SLOT[a], "P" if eta[a] > 0 else "N") for a in range(8)]
hat = [kron4(*[MATRIX_OF[name] for name in FACTORS[a]]) for a in range(8)]
```

`factor_names` writes the recipe as a list of four letters: `"G"` repeated for the slots before the own slot, the letter `middle` in it, and `"I"` after it. `FACTORS` gives every direction its four letters, with `P` for a space-like and `N` for a time-like direction; `hat` turns the letters into matrices with `MATRIX_OF` and forms their Kronecker product: the eight hat gammas, in the order $x_0, \ldots, x_7$.

```
for a in range(8):
    kind = "space-like" if eta[a] > 0 else "time-like "
    print(f"hat gamma^({COORDINATES[a]})  {kind}  = " + " (x) ".join(FACTORS[a]))
check(COORDINATES == [f"x{k}" for k in range(8)]
      and eta == [1, 1, 1, 1, -1, -1, -1, -1],
      "the record lists x0..x7 with eta = diag(+1, +1, +1, +1, -1, -1, -1, -1)")
```

One printed line per direction with its four factors (the table of Section 4.17). The check confirms the coordinates and signs read from the record.

In [5], figure 1.

```
PAIR_ORDER = [1, 6, 2, 5, 3, 4, 0, 7]  # x1, x6, x2, x5, x3, x4, x0, x7
ROLE = ["hidden", "3-space", "3-space", "3-space", "the time", "extra time",
        "extra time", "extra time"]
CODE = {"I": 0, "G": 1, "P": 2, "N": 3}  # a number per letter, for the colours
grid = np.array([[CODE[name] for name in FACTORS[a]] for a in PAIR_ORDER])
slot_colours = ListedColormap(["#ffffff", "#c3c2b7", "#e34948", "#2a78d6"])
```

The rows of the figure are ordered by the pairs that share a slot. Every letter gets a number (`CODE`), and `grid` is the 8×4 table of these numbers; the four colours are white for I_2, grey for G, red for P and blue for N.

```
fig, ax = plt.subplots(figsize=(7.0, 4.8), layout="constrained")
# aspect="auto": the squares become rectangles that fill the panel
ax.imshow(grid, cmap=slot_colours, norm=BoundaryNorm([-0.5, 0.5, 1.5, 2.5, 3.5], 4),
          aspect="auto")
for row, a in enumerate(PAIR_ORDER):
    for column, name in enumerate(FACTORS[a]):
        text = "$I_2$" if name == "I" else name
        colour = "white" if name in ("P", "N") else "#0b0b0b"
        ax.text(column, row, text, ha="center", va="center", fontsize=12,
                color=colour)
```

The table is painted, and every cell gets its letter (I_2 typeset as mathematics), white on the dark colours and black on the light ones.

```
ax.set_xticks(range(4), [f"slot {k}" for k in range(1, 5)])
ax.set_yticks(range(8), [f"$x_{a}$ ({ROLE[a]})" for a in PAIR_ORDER])
for boundary in (1.5, 3.5, 5.5):  # lines between the four pairs
    ax.axhline(boundary, color="#0b0b0b", linewidth=1.2)
ax.grid(False)
ax.set_title("$\\hat\\gamma$ = slot 1 $\\otimes$ slot 2 $\\otimes$ slot 3 "
             "$\\otimes$ slot 4")
save_figure(fig, "slot_pattern",
            ...)
```

Columns and rows are labelled, black lines separate the four pairs, and the title states the recipe. **What figure 1 shows and why:** a staircase: each pair has its own slot with a red P and a blue N, grey G before it and white I_2 after it; this staircase is what makes all eight anticommute (Section 4.17).

In [6], figure 2.

```
SIGN_COLOURS = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])  # -1, 0, +1
SIGN_NORM = BoundaryNorm([-1.5, -0.5, 0.5, 1.5], SIGN_COLOURS.N)
```

```
def draw_signs(ax, matrix, title):
    """Draw a matrix with entries -1, 0, +1 as a heat map in the panel ax."""
    ax.imshow(matrix, cmap=SIGN_COLOURS, norm=SIGN_NORM)
    ax.set_title(title, fontsize=10)
    ax.set_xticks(range(0, 16, 4))
    ax.set_yticks(range(0, 16, 4))
    ax.grid(False)  # no grid lines on top of the coloured squares

def sign_legend(fig):
    """The key of the three colours, below the panels of the figure."""
    handles = [Patch(facecolor=SIGN_COLOURS(k), edgecolor="#898781", label=label)
               for k, label in enumerate(["entry -1", "entry 0", "entry +1"])]
    fig.legend(handles=handles, loc="outside lower center", ncol=3, fontsize=9,
               frameon=False)
```

The three-colour heat map and its key, as in Notebook 04a (without the numbers in the squares).

```
fig, axes = plt.subplots(2, 4, figsize=(8.8, 5.0), layout="constrained")
for a in range(8):  # a // 4 is the row of the panel, a % 4 its column
    draw_signs(axes[a // 4, a % 4], hat[a], f"$\\hat\\gamma^{{(x_{a})}}$")
sign_legend(fig)
save_figure(fig, "tensor_gammas",
            ...)
```

The eight hat gammas in two rows of four panels. **What figure 2 shows and why:** each is a signed permutation matrix, but the pattern differs from the author's: a P or N in slot k exchanges components whose numbers differ in bit k, so the coloured squares lie on diagonals at the distance 8 (slot 1), 4 (slot 2), 2 (slot 3) or 1 (slot 4) from the main diagonal, and the factors G in front flip signs ($\hat\gamma^{(x_1)}$ and $\hat\gamma^{(x_6)}$, with nothing before slot 1, show two clean diagonals at distance 8).

In [7], the Clifford relation and the 256 products.

```
clifford_ok = all(
    (hat[a] @ hat[b] + hat[b] @ hat[a] == 2 * eta[a] * (a == b) * I16).all()
    for a in range(8) for b in range(8))  # (a == b) is 1 or 0
permutation_ok = all((np.count_nonzero(m, axis=0) == 1).all()
                     and (np.count_nonzero(m, axis=1) == 1).all()
                     and (np.abs(m).sum() == 16) for m in hat)
symmetry_ok = all((hat[a].T == eta[a] * hat[a]).all() for a in range(8))
check(clifford_ok and permutation_ok and symmetry_ok,
      "hat gammas: Clifford relation (64 pairs), signed permutations, symmetry")
```

The Clifford relation for all 64 ordered pairs (in arithmetic, `(a == b)` counts as 1 or 0, so `2 * eta[a] * (a == b)` is $2\eta^{ab}$); signed permutations (one nonzero per column and per row, and the absolute values add up to 16, so every nonzero is ±1); and the symmetry pattern $(\hat\gamma^{(x_a)})^T = \eta_{aa}\hat\gamma^{(x_a)}$.

```
SETS = [s for k in range(9) for s in itertools.combinations(range(8), k)]
```

```
def product(matrices, indices):
    """The product of matrices[i] for i in indices, from left to right."""
    result = I16
    for i in indices:
        result = result @ matrices[i]
    return result

author_products = np.array([product(gamma, s) for s in SETS])  # gamma_A, 256 of them
hat_products = np.array([product(hat, s) for s in SETS])  # hat gamma_A
```

The 256 sets as in Notebook 04c; `product` multiplies the listed matrices from left to right; the 256 products of both sets are stored, each as an array of shape (256, 16, 16).

```
def exact_rank(rows):
    """The exact rank of a list of rows of whole numbers (fractions, over QQ)."""
    matrix = DomainMatrix([[sp.ZZ(int(x)) for x in row] for row in rows],
                          (len(rows), len(rows[0])), sp.ZZ)
    return matrix.convert_to(sp.QQ).rank()

hat_rank = exact_rank(hat_products.reshape(256, 256).tolist())
report("exact rank of the 256 products of the hat gammas", hat_rank)
check(hat_rank == 256, "the 256 hat products are a basis of all real 16 x 16 matrices")
```

The exact rank of Notebook 04c, applied to the 256 hat products written as rows: 256, so they too are a basis of all real 16×16 matrices.

In [8], the products of all eight gammas.

```
WOLFRAM = "Revision/algebra/reports/wolfram-algebra.json"
PYTHON = "Revision/algebra/reports/python-algebra.json"
RECORDED = {}  # report file -> {check name: the check (name, verdict, detail)}
for report_file in (WOLFRAM, PYTHON):
    text = repository_file(report_file).read_text(encoding="utf-8")
    RECORDED[report_file] = {e["name"]: e for e in json.loads(text)["checks"]}

def check_record(condition, name, *records):
    """check(condition, name) for a statement that the Revision record verified;
    records are pairs (report file, check name), each recorded as passed."""
    for report_file, check_name in records:
        entry = RECORDED[report_file].get(check_name)
        if entry is None or entry["verdict"].upper() != "PASS":
            raise AssertionError(f"{report_file} has no passed check {check_name}")
    check(condition, name)
    for report_file, check_name in records:
        print(f"     reproduces {report_file}")
        print(f"         check {check_name}")
```

The two algebra reports and the function `check_record`, as in Notebook 04a (without the set of reproduced checks).

```
def permutation_sign(numbers):
    """+1 for an even, -1 for an odd number of inversions (pairs i < j with
    numbers[i] > numbers[j])."""
    inversions = sum(1 for i, j in itertools.combinations(range(len(numbers)), 2)
                     if numbers[i] > numbers[j])
    return -1 if inversions % 2 else 1
```

The permutation sign of Section 4.2, for lists without repetitions.

```
PAIRS = [(1, 6), (2, 5), (3, 4), (0, 7)]  # (x1,x6) (x2,x5) (x3,x4) (x0,x7)
pair_ok = True
for slot, (s, t) in enumerate(PAIRS, start=1):
    only_g = kron4(*[G if k == slot else I2 for k in range(1, 5)])
    pair_ok &= bool((hat[s] @ hat[t] == -only_g).all())
```

For each slot (`enumerate(..., start=1)` numbers the pairs from 1), the product of its two hat gammas must be minus the matrix with G in that slot and I_2 elsewhere.

```
AUTHOR_ORDER = [0, 1, 2, 3, 4, 5, 6, 7]  # x0, x1, x2, ..., x7
paired_order = [a for pair in PAIRS for a in pair]  # x1, x6, x2, x5, x3, x4, x0, x7
# where each factor of the paired order stands in the author's order
positions = [AUTHOR_ORDER.index(a) for a in paired_order]
reorder_sign = permutation_sign(positions)
say(f"positions of x1, x6, x2, x5, x3, x4, x0, x7 in the author's order: {positions}")
say(f"permutation sign of the reordering: {reorder_sign:+d}")
```

`AUTHOR_ORDER` is the order of the factors in the author's product $\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$; `paired_order` lists the directions pair by pair; `.index(a)` finds where each stands in the author's order. The printed list of positions is $[1, 6, 2, 5, 3, 4, 0, 7]$; it has 12 inversions (1 before 0; 6 before $2, 5, 3, 4, 0$; 2 before 0; 5 before $3, 4, 0$; 3 before 0; 4 before 0), an even number, so the sign is $+1$.

```
chirality_hat = product(hat, AUTHOR_ORDER)
gggg = kron4(G, G, G, G)
bits = [format(j, "04b") for j in range(16)]  # "0000", "0001", ..., "1111"
parity = [(-1) ** b.count("1") for b in bits]  # -1 for an odd number of 1s
check(pair_ok and (chirality_hat == reorder_sign * gggg).all()
      and (np.diag(chirality_hat) == parity).all()
      and (chirality_hat == np.diag(parity)).all(),
      "hat Gamma = (sign +1) G (x) G (x) G (x) G = diag((-1)^(b1+b2+b3+b4))")
```

$\hat{\Gamma}$ is the product of the hat gammas in the author's order. `format(j, "04b")` writes j with four binary digits, and `parity` is (-1) to the number of ones. The check requires the pair products, $\hat{\Gamma} = (+1)\, G \otimes G \otimes G \otimes G$, and that $\hat{\Gamma}$ is the diagonal matrix of the parities.

```
chirality_author = product(gamma, AUTHOR_ORDER)
say("rows with -1 on the diagonal, author: "
    f"{[j for j in range(16) if chirality_author[j, j] < 0]}")
say("rows with -1 on the diagonal, hat:    "
```

```
    f"{[j for j in range(16) if chirality_hat[j, j] < 0]}")
check_record((chirality_author == np.diag([-1] * 8 + [1] * 8)).all(),
             "author: Gamma = gamma^(x0) gamma^(x1) ... gamma^(x7) = diag(-I8, I8)",
             (WOLFRAM, "Gamma_diag"), (PYTHON, "chirality_diag"))
```

The same product of the author's gammas. The two printed lines list the rows with -1: 0 to 7 for the author, $1, 2, 4, 7, 8, 11, 13, 14$ for the hat set. The check confirms the author's $\mathrm{diag}(-I_8, I_8)$ and names the two Revision checks.

In [9], figure 3.

```
fig, (top, bottom) = plt.subplots(2, 1, figsize=(8.0, 5.4), layout="constrained")
for ax, values, title in (
        (top, np.diag(chirality_author), "author: $\\Gamma = $ "
         "$\\gamma^{(x_0)}\\gamma^{(x_1)}\\cdots\\gamma^{(x_7)}$"),
        (bottom, np.diag(chirality_hat), "tensor picture: $\\hat\\Gamma = "
         "G \\otimes G \\otimes G \\otimes G$")):
    colours = ["#2a78d6" if v < 0 else "#e34948" for v in values]
    ax.bar(range(16), values, color=colours, width=0.7)
    ax.axhline(0.0, color="#898781", linewidth=0.8)
    ax.set_ylim(-1.4, 1.4)
    ax.set_yticks([-1, 0, 1])
    ax.set_ylabel("diagonal entry")
    ax.set_title(title, fontsize=10)
top.set_xticks(range(16))
bottom.set_xticks(range(16), [f"{j}\n{bits[j]}" for j in range(16)], fontsize=8)
bottom.set_xlabel("row number $j$ and its bits $b_1 b_2 b_3 b_4$")
save_figure(fig, "chirality_diagonals",
            ...)
```

Two bar charts, one above the other: the 16 diagonal entries of the author's product and of the hat product, blue for -1 and red for $+1$; the lower one labels every row with its number and, on a second line (`"\n"` starts a new line), its bits. **What figure 3 shows and why:** the author's diagonal is eight blue bars followed by eight red ones; the hat diagonal alternates in a pattern that follows the parity of the bits. Both have eight entries of each sign, so a renumbering of the components can turn one into the other; In [10] finds it.

In [10], the change of basis.

```
def change_of_basis(products_1, products_2, i, j):
    """S = sum_A products_1[A] E_ij products_2[A]^T as one matrix product:
    products_1[:, :, i] is the table of the columns i (256 rows of 16 numbers)."""
    return products_1[:, :, i].T @ products_2[:, :, j]
```

The term $\gamma_A E_{ij} \hat{\gamma}_A^T$ has the entry $(\gamma_A)_{ki}(\hat{\gamma}_A)_{lj}$ in row k, column l (only column i of γ_A and column j of $\hat{\gamma}_A$ survive). `products_1[:, :, i]` is the 256×16 table whose row A is column i of γ_A; transposed and multiplied with the same table of the hat products for column j, it gives $\sum_A (\gamma_A)_{ki}(\hat{\gamma}_A)_{lj}$ for all k, l: the whole sum S for $M = E_{ij}$ in one matrix product.

```
def first_nonzero(products_1, products_2):
    """The first (i, j) in reading order with a nonzero S, and that S."""
```

```
    for i, j in itertools.product(range(16), repeat=2):
        S = change_of_basis(products_1, products_2, i, j)
        if S.any():
            return i, j, S
    raise ValueError("every S is zero")
```

`first_nonzero` tries $(i, j) = (0, 0), (0, 1), \ldots$ in this order and returns the first pair with a nonzero S, and that S.

```
i0, j0, S = first_nonzero(author_products, hat_products)
E = np.zeros((16, 16), dtype=np.int64)
E[i0, j0] = 1  # the matrix E_ij with a single 1
plain_sum = sum(author_products[t] @ E @ hat_products[t].T for t in range(256))
report("first (i, j) with a nonzero S", (i0, j0))
report("the different entries of S", sorted(set(int(x) for x in S.flatten())))
```

The first nonzero S belongs to $(i, j) = (0, 8)$. As a control, `plain_sum` computes $\sum_A \gamma_A E_{08} \hat{\gamma}_A^T$ term by term. The entries of S are -16, 0 and 16.

```
c = int((S.T @ S)[0, 0])  # the factor c in S^T S = c I16
root = int(round(c ** 0.5))  # its square root, a whole number here
report("c in S^T S = c I16, and its square root", (c, root))
check((plain_sum == S).all()
      and all((gamma[a] @ S == S @ hat[a]).all() for a in range(8))
      and (S.T @ S == c * I16).all() and root * root == c,
      "S intertwines: gamma^a S = S hat gamma^a for all 8 a, and S^T S = c I16")
```

c is read off the upper-left entry of $S^T S$: 256, with the square root 16 (`c ** 0.5` is the square root, `round` and `int` make it a whole number, and `root * root == c` confirms that it is exact). The check requires that the shortcut equals the plain sum, that S intertwines all eight pairs of gammas, and that $S^T S = c\, I_{16}$.

```
Q = S // root  # exact: every entry of S is a multiple of root
codes = []
for row in Q:
    column = int(np.flatnonzero(row)[0])  # the column of the nonzero entry
    codes.append(("+" if row[column] > 0 else "-") + str(column))
say("rows 0 to 15 of Q: " + " ".join(codes))
check((Q * root == S).all() and (np.count_nonzero(Q, axis=0) == 1).all()
      and (np.count_nonzero(Q, axis=1) == 1).all() and (Q.T @ Q == I16).all(),
      "Q = S / sqrt(c) is a signed permutation matrix (orthogonal)")
```

$Q = S/16$, computed exactly by whole-number division; its codes are printed, $+8\ +4\ +2\ -14\ -7\ +11\ -13\ -1\ -9\ -5\ -3\ +15\ -6\ +10\ -12\ -0$. The check confirms that the division was exact and that Q is an orthogonal signed permutation matrix.

In [11], all products, and the formula for S.

```
all_products_ok = all((author_products[t] == Q @ hat_products[t] @ Q.T).all()
                      for t in range(256))
```

```
check(all_products_ok and (chirality_author == Q @ chirality_hat @ Q.T).all(),
      "gamma_A = Q hat gamma_A Q^T for all 256 products, and Gamma = Q hat Gamma Q^T")
```

Not only the eight gammas but all 256 products, and the product of all eight, transform with Q.

```
formula_ok = all((change_of_basis(author_products, hat_products, i, j)
                  == 16 * Q[i, j] * Q).all()
                 for i, j in itertools.product(range(16), repeat=2))
nonzero_positions = int(np.count_nonzero(Q))
report("positions (i, j) with a nonzero S(E_ij)", nonzero_positions)
check(formula_ok and nonzero_positions == 16,
      "S(E_ij) = 16 Q_ij Q for all 256 positions (i, j)")
```

For every one of the 256 choices $M = E_{ij}$, $S = 16\,Q_{ij}\,Q$. (Reason: $\sum_A \hat\gamma_A Y \hat\gamma_A^T$ commutes with every hat gamma by the argument of Section 4.17, so it is a multiple of I_{16}; its trace is $\sum_A \operatorname{tr}(Y\hat\gamma_A^T\hat\gamma_A) = 256\operatorname{tr}Y$, so it is $16\operatorname{tr}(Y)\,I_{16}$; with $\gamma_A = Q\hat\gamma_A Q^T$ and $Y = Q^T E_{ij}$ this gives $S(E_{ij}) = 16\operatorname{tr}(Q^T E_{ij})\,Q = 16\,Q_{ij}\,Q$.) So S is nonzero exactly at the 16 positions where Q has its nonzero entries, and the first of them in reading order is $(0, 8)$, as found.

In [12], figure 4.

```
fig, ax = plt.subplots(figsize=(6.0, 6.0), layout="constrained")
draw_signs(ax, Q, "$Q$: $\\gamma^{(x_a)} = Q\\,\\hat\\gamma^{(x_a)} Q^T$")
ax.set_xticks(range(16), [f"{j} ({bits[j]})" for j in range(16)], fontsize=6,
              rotation=90)
ax.set_yticks(range(16), [str(i) for i in range(16)], fontsize=8)
ax.set_xlabel("component $j$ of the tensor basis (its bits)")
ax.set_ylabel("component $i$ of the author's basis")
for i in range(16):
    j = int(np.flatnonzero(Q[i])[0])
    ax.text(j, i, f"{Q[i, j]:+d}", ha="center", va="center", color="white",
            fontsize=7)
sign_legend(fig)
save_figure(fig, "change_of_basis",
            ...)
```

Q as a heat map; the columns are labelled with their number and bits (turned by 90 degrees), and the single nonzero entry of every row is written into its square. **What figure 4 shows and why:** sixteen coloured squares, one in each row and each column: Q renumbers the components and flips some signs. The first eight rows use exactly the columns whose bits contain an odd number of ones, where $\hat\Gamma = -1$; this moves the eight entries -1 of $\hat\Gamma$ to the top, as in the author's $\operatorname{diag}(-I_8, I_8)$.

In [13], only one change of basis.

```
def intertwiner_system(left, right):
    """The 2048 x 256 matrix of the equations left[a] X - X right[a] = 0, a = 1..8,
    for the 256 entries of X read row by row."""
    return np.vstack([np.kron(left[a], I16) - np.kron(I16, right[a].T)
                      for a in range(8)])
```

The equations $LX - XR = 0$ for the 256 entries of X, read row by row (entry (k, l) is unknown number $16k + l$). With this numbering, LX is $(L \otimes I_{16})$ times the list of unknowns: by the index formula, $(L \otimes I_{16})_{16i+j,\,16k+l} = L_{ik}\delta_{jl}$, and summing over k, l against X_{kl} gives $\sum_k L_{ik}X_{kj} = (LX)_{ij}$. In the same way XR is $(I_{16} \otimes R^T)$ times the list: $(I_{16} \otimes R^T)_{16i+j,\,16k+l} = \delta_{ik}R_{lj}$, which gives $\sum_l X_{il}R_{lj} = (XR)_{ij}$. `np.vstack` stacks the eight blocks of 256 equations into the 2048×256 system.

```
system = intertwiner_system(gamma, hat)  # the author's gammas and the hat gammas
commutant = intertwiner_system(gamma, gamma)  # the author's gammas on both sides
rank_system, rank_commutant = exact_rank(system.tolist()), exact_rank(
    commutant.tolist())
report("exact ranks of the two systems (2048 equations, 256 unknowns)",
       (rank_system, rank_commutant))
```

Two systems: the intertwiners from the hat gammas to the author's, and the matrices that commute with all eight of the author's gammas. Both have the exact rank 255, so each solution space has the dimension $256 - 255 = 1$ (the number of unknowns minus the number of independent equations).

```
q_solves = not (system @ Q.reshape(256)).any()  # Q, read row by row, solves it
check(rank_system == 255 and q_solves,
      "the intertwiners form a space of dimension 1: the multiples of Q")
```

Q, written as a list of 256 numbers, solves the first system; with the dimension 1, the solutions are exactly the multiples of Q.

```
python_detail = RECORDED[PYTHON]["pin_commutant_dimension_1"]["detail"]
wolfram_detail = RECORDED[WOLFRAM]["Pin44_irreducible_commutant_dim_1"]["detail"]
check_record(256 - rank_commutant == 1 and not (commutant @ I16.reshape(256)).any()
             and "= 1 (Fraction), 1 (sympy)" in python_detail
             and "has dimension 1" in wolfram_detail,
             "only the multiples of I16 commute with all eight author's gammas",
             (PYTHON, "pin_commutant_dimension_1"),
             (WOLFRAM, "Pin44_irreducible_commutant_dim_1"))
```

The second system has a one-dimensional solution space, and I_{16} solves it: only the multiples of I_{16} commute with all eight of the author's gammas. The check also requires the two Revision checks to state the dimension 1 in their own words, and names them.

In [14], the penalty matrix.

```
K = system.T @ system  # 256 x 256, whole numbers
penalty = []  # 4 n_B for every set B
eigen_ok = True
for t, s in enumerate(SETS):
    k = len(s)
    n_B = k if k % 2 == 0 else 8 - k  # the number of anticommuting directions
    v = (Q @ hat_products[t]).reshape(256)  # X_B = Q hat gamma_B, row by row
    eigen_ok &= bool((K @ v == 4 * n_B * v).all())
    penalty.append(4 * n_B)
```

$K = A^T A$ is computed with whole numbers. For each set B of degree k, n_B is k for even k and $8-k$ for odd k; the column v lists the entries of $X_B = Q\hat{\gamma}_B$; and `eigen_ok` stays true only if $Kv = 4n_B v$ exactly, line 5 of the derivation in Section 4.17.

```
values = list(range(0, 33, 4))  # 0, 4, ..., 32
multiplicities = [penalty.count(v) for v in values]
numeric = np.linalg.eigvalsh(K.astype(float))  # floating-point eigenvalues
rounded = np.round(numeric).astype(int)  # nearest whole numbers
numeric_ok = np.max(np.abs(numeric - rounded)) < 1e-9 and all(
    int(np.sum(rounded == v)) == m for v, m in zip(values, multiplicities))
report("multiplicities of 0, 4, ..., 32 in K", multiplicities)
check(eigen_ok and multiplicities == [comb(8, j) for j in range(9)] and numeric_ok,
      "K = A^T A has the exact eigenvalues 4 n_B; only Q has the eigenvalue 0")
```

The multiplicities of $0, 4, \ldots, 32$ are counted: $1, 8, 28, 56, 70, 56, 28, 8, 1$. As an independent control, numpy computes all 256 eigenvalues of K in floating point; they must lie within 10^{-9} of whole numbers and come with the same multiplicities. The check requires the exact eigenvectors, the binomial multiplicities and the numerical agreement.

In [15], figure 5.

```
fig, ax = plt.subplots(figsize=(7.2, 3.9), layout="constrained")
ax.set_axisbelow(True)  # grid lines behind the bars
colours = ["#eb6834" if v == 0 else "#2a78d6" for v in values]
bars = ax.bar(values, multiplicities, width=2.8, color=colours)
ax.bar_label(bars, labels=[str(m) for m in multiplicities], padding=2, fontsize=9)
ax.set_xticks(values)
ax.set_ylim(0, 80)
ax.set_xlabel("eigenvalue of $K = A^T A$ (the penalty of a candidate $X$)")
ax.set_ylabel("multiplicity")
ax.set_title("$\\gamma^{(x_a)}X - X\\hat\\gamma^{(x_a)} = 0$: one solution, $X = Q$")
save_figure(fig, "penalty_spectrum",
            ...)
```

A bar chart of the multiplicities against the eigenvalues, the bar of the eigenvalue 0 in orange. **What figure 5 shows and why:** one orange bar of height 1 at 0 (only Q solves all 2048 equations) and blue bars of the binomial heights 8, 28, 56, 70, 56, 28, 8, 1 at 4 to 32: the part of any matrix that is perpendicular to Q makes the sum of the squared equations at least 4 times its squared size.

In [16], another way to fill the slots.

```
SLOT_2 = [4, 1, 2, 3, 1, 2, 3, 4]  # pairs (x1,x4) (x2,x5) (x3,x6) (x0,x7)
FACTORS_2 = [factor_names(SLOT_2[a], "P" if eta[a] > 0 else "N") for a in range(8)]
hat_2 = [kron4(*[MATRIX_OF[name] for name in FACTORS_2[a]]) for a in range(8)]
clifford_2 = all(
    (hat_2[a] @ hat_2[b] + hat_2[b] @ hat_2[a] == 2 * eta[a] * (a == b) * I16).all()
    for a in range(8) for b in range(8))
check(clifford_2 and all((hat_2[a].T == eta[a] * hat_2[a]).all() for a in range(8)),
      "second assignment: the Clifford relation and the symmetry pattern hold too")
hat_2_products = np.array([product(hat_2, s) for s in SETS])
```

The second assignment of directions to slots, with the pairs (x_1, x_4), (x_2, x_5), (x_3, x_6), (x_0, x_7); the same recipe builds `hat_2`; the check confirms the Clifford relation and the symmetry pattern; and the 256 products of the new set are formed.

```
def diagonal_sets(products):
    """The sets A (as coordinate names) whose product is a diagonal matrix."""
    return [tuple(COORDINATES[a] for a in s) for s, m in zip(SETS, products)
            if (m == np.diag(np.diag(m))).all()]
```

`diagonal_sets` lists, as tuples of coordinate names, the sets whose product is a diagonal matrix.

```
diagonal_author = diagonal_sets(author_products)
say("diagonal products, author:            " + ", ".join(
    "".join(n[1] for n in s) or "I" for s in diagonal_author[:5]) + ", ...")
say("diagonal products, second assignment: " + ", ".join(
    "".join(n[1] for n in s) or "I" for s in diagonal_sets(hat_2_products)[:5])
    + ", ...")
check(len(diagonal_author) == 16 and diagonal_sets(hat_products) == diagonal_author
      and diagonal_sets(hat_2_products) != diagonal_author,
      "the first assignment has the author's 16 diagonal products, the second not")
```

The first five diagonal products of each set are printed by their coordinate numbers (`n[1]` is the digit of a name such as `"x6"`; `or "I"` names the empty set): I, 07, 16, 25, 34 for the author, but I, 07, 14, 25, 36 for the second assignment. The check requires 16 diagonal products for the author, the same sets for the first hat set, and different sets for the second: by the argument of Section 4.17, no signed permutation can relate the second set to the author's.

```
i2, j2, S_2 = first_nonzero(author_products, hat_2_products)
c_2 = int((S_2.T @ S_2)[0, 0])
report("second assignment: entries of S_2 and c_2",
       (sorted(set(int(x) for x in S_2.flatten())), c_2))
check(all((gamma[a] @ S_2 == S_2 @ hat_2[a]).all() for a in range(8))
      and (S_2.T @ S_2 == c_2 * I16).all() and c_2 == 128
      and (np.count_nonzero(S_2, axis=1) == 2).all(),
      "second assignment: S_2 intertwines, S_2^T S_2 = 128 I16, two entries per row")
Q_2 = S_2 / np.sqrt(c_2)  # floating point: the entries are +-1/sqrt(2)
```

The same formula gives a change of basis S_2 for the second set: entries -8, 0, 8, $S_2^T S_2 = 128\, I_{16}$, two nonzero entries in every row. So $Q_2 = S_2/\sqrt{128}$ has the entries $\pm 8/\sqrt{128} = \pm 1/\sqrt{2}$, computed in floating point: an orthogonal matrix that mixes the components in pairs, not a signed permutation.

In [17], figure 6.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(8.8, 4.6), layout="constrained")
for ax, matrix, title in (
        (left, Q, "pairs (x1,x6) (x2,x5) (x3,x4) (x0,x7): $Q$"),
        (right, Q_2, "pairs (x1,x4) (x2,x5) (x3,x6) (x0,x7): $Q_2$")):
    image = ax.imshow(matrix, cmap="RdBu_r", vmin=-1.0, vmax=1.0)
    ax.set_title(title, fontsize=9)
```

```
    ax.set_xticks(range(0, 16, 4))
    ax.set_yticks(range(0, 16, 4))
    ax.set_xlabel("tensor component $j$")
    ax.set_ylabel("author's component $i$")
    ax.grid(False)
fig.colorbar(image, ax=[left, right], shrink=0.8, label="entry")
save_figure(fig, "two_assignments",
            ...)
```

Q and Q_2 side by side with one continuous colour scale (`"RdBu_r"`: blue for -1, white for 0, red for $+1$; `vmin` and `vmax` fix its ends), and a colour bar explaining it. **What figure 6 shows and why:** on the left sixteen full-coloured squares, one per row and column; on the right thirty-two paler squares, two per row and column, of the size $1/\sqrt{2} \approx 0.71$. Both matrices are orthogonal and both turn one set of gammas exactly into the other; only the assignment that matches the author's pairs gives a pure renumbering.

In [18], the last check.

```
names = ["04d_1_slot_pattern.png", "04d_2_tensor_gammas.png",
         "04d_3_chirality_diagonals.png", "04d_4_change_of_basis.png",
         "04d_5_penalty_spectrum.png", "04d_6_two_assignments.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in names),
      "all six figure files exist")
all_checks_passed()
```

The six figure files must exist; the last line reads ALL 18 CHECKS PASSED (notebook 04d): one check in each of In [2], In [3], In [4], In [14] and In [18]; two in each of In [7], In [8], In [10], In [11] and In [13]; and three in In [16].

4.21 What we proved, what we computed, what we assumed

PROVED (exact; the proof is in this chapter, and the computer confirms it with exact arithmetic in the notebook named):

- The square of a linear expression $\sum_a p_a \gamma^a$ is the quadratic form $\sum_a \eta^{aa} p_a^2$ exactly when the coefficients satisfy the Clifford relation; no ordinary numbers do (Section 4.3; Notebook 04b).
- The author's formulas give six 4×4 blocks equal to the six matrices his notebook displays; they are the right (s4) and minus the left (t4) multiplications by the quaternion units, which gives all their rules; the 8×8 matrices satisfy $\tau_1\tau_2\tau_3 = \tau_4\tau_5\tau_6\tau_7 = \sigma$, $\tau_7 = \mathrm{diag}(-I_4, I_4)$, $\bar{\tau}_A = -\tau_A$ and the key rule; the sixteen-by-sixteen matrices T16 satisfy the Clifford relation, and $\mathrm{T16}[8] = \mathrm{diag}(-I_8, I_8)$; named with the coordinate map ($\gamma^{(x_k)} = \mathrm{T16}[k]$ for $k = 0, \ldots, 7$) they satisfy $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I_{16}$ with $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$; they are real signed permutation matrices, symmetric for x_0, x_1, x_2, x_3 and antisymmetric for the time x_4 and the deflating extra times x_5, x_6, x_7 (Section 4.5; Notebook 04a).
- The author's gammas take the square root of the 4+4 quadratic form; plane waves of the flat equation $\sum_a \gamma^{(x_a)} \partial_a \Psi = m\Psi$ obey $E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$; without

extra-time momentum h is Hermitian and commutes with the record's matrix $B = -iC\gamma^{(x_4)}$, while a momentum along an extra time mixes the sectors $B = +1$ and $B = -1$; the record's example has the energies ± 5, eight times each on all sixteen components and four times each in the sector $B = +1$; with a momentum along an extra time the energies become imaginary once $k_5^2 > m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2$, with the growth rate $\sqrt{k_5^2 - m^2 - k_0^2 - k_1^2 - k_2^2 - k_3^2}$, which has no upper bound; the record's example $m = 1$, $k_5 = 2$ has $E = \pm i\sqrt{3}$, eight times each (Section 4.9; Notebook 04b).

- The 256 products of the gammas multiply by rule R1, square to $\pm I_{16}$ by rule R2, have trace 0 except I_{16}, are perpendicular in the trace sense and independent: Cl(4,4) is the set of all real 16×16 matrices; 136 products are symmetric and 120 antisymmetric; the 128 even ones span the block diagonal matrices and the 128 odd ones the block off-diagonal matrices; eight gamma matrices need at least sixteen components; $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b] = \frac{1}{2}\gamma^a\gamma^b$, with 12 rotation planes and 16 boost planes (Section 4.13; Notebook 04c).
- A second set of real gammas, built from P, N and G with Kronecker products, satisfies the same Clifford relation; the author's gammas are this set with the sixteen components renumbered and some signs flipped, $\gamma^{(x_a)} = Q\hat{\gamma}^{(x_a)}Q^T$ with a signed permutation Q; this change of basis is unique up to a factor; and only the multiples of I_{16} commute with all eight of the author's gammas (Section 4.17; Notebook 04d).

The Revision record confirms these statements independently. The table names the record file and its checks for each of them; the notebook named in the list above reproduces every one of these checks and prints it. For the four theory checks of Section 4.9, Notebook 04b also requires that the record's text states the same formulas and examples word for word, so a later change of the record would make the notebook fail instead of going unnoticed.

COMPUTED (floating-point numbers, with the measured accuracy): the eigenvalues of the 2×2 roots agree with $\pm\sqrt{p^2 \pm 1}$ to 10^{-12}; $(\sum_a p_a \gamma^{(x_a)})^2 = \eta(p,p) I_{16}$ for 300 random vectors, every deviation below 10^{-12} (the bound that the notebook asserts; the sizes themselves, plotted in figure 4 of Notebook 04b, depend on the computer's numerical library); the sixteen energies of the good-sector example lie within 10^{-12} of ± 5, with eight independent solutions at each energy, the eight energies in the sector $B = +1$ lie within 10^{-12} of ± 5, four of each, and the smallest singular value of $EI_{16} - h$ equals the distance to ± 5 within 10^{-9}; the 160×16 energies with a momentum k_5 lie within 10^{-10} of $\pm\sqrt{25 - k_5^2}$; the floating-point eigenvalues of the penalty matrix K lie within 10^{-9} of $0, 4, \ldots, 32$ (Notebooks 04b and 04d). Each of these confirms an exact statement proved above.

ASSUMED: the author's metric, the roles of his coordinates and his formulas for T16 (the input of the theory; Section 4.4 and Section 4.5); in Section 4.9, flat 4+4 space without self-interaction, a model of the algebra only, since the author's extra times deflate at every moment; and two facts of linear algebra quoted without proof: in a space of dimension m any m independent elements form a basis (Section 4.13), and the number of singular values of a square matrix M that are 0 is the number of independent solutions u of $Mu = 0$ (used for the counts of Notebook 04b). The fact that the trace of every square matrix is the sum of its eigenvalues, counted with their multiplicities, is not assumed here: Section 1.34 proves it from the fundamental theorem of algebra, which Chapter 1

assumes.

HYPOTHESIS and OPEN: this chapter states none. What the growing waves along the extra times mean for the curved, deflating space-time is the subject of Chapter 8. Nothing in this chapter concerns the creation of universes or matter and antimatter; the matrices it builds are used in Part V, where the honest scope of those questions is stated.

4.22 Exercises

Exercise 1. Show that the three real matrices σ_x, σ_z and N of Section 4.3 satisfy $(p\sigma_x+q\sigma_z+rN)^2 = (p^2+q^2-r^2)I_2$ for all p, q, r. Compute $\sigma_x\sigma_z N$. Then prove that no real 2×2 matrix M with $M^2 = +I_2$ anticommutes with both σ_x and σ_z, and explain why three anticommuting matrices fit into 2×2 although $2^3 = 8 > 2^2$.

Answer. The squares are $\sigma_x^2 = \sigma_z^2 = I_2$ and $N^2 = -I_2$. The pairs anticommute: $\sigma_z\sigma_x = -\sigma_x\sigma_z$ (Section 4.2) and $N\sigma_x = -\sigma_x N$ (Section 4.3), and $\sigma_z N = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $N\sigma_z = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} = -\sigma_z N$. So the general rule of Section 4.3 with the signs $(+1,+1,-1)$ gives $(p^2+q^2-r^2)I_2$. Next, $\sigma_x\sigma_z = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = -N$, so $\sigma_x\sigma_z N = -N^2 = I_2$. For the second part, every real 2×2 matrix is $\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \frac{\alpha+\delta}{2}I_2 + \frac{\beta+\gamma}{2}\sigma_x + \frac{\alpha-\delta}{2}\sigma_z + \frac{\beta-\gamma}{2}N$ (check the four entries), so write $M = aI_2 + b\sigma_x + c\sigma_z + dN$. Then $\sigma_x M + M\sigma_x = 2a\sigma_x + 2bI_2 + c(\sigma_x\sigma_z + \sigma_z\sigma_x) + d(\sigma_x N + N\sigma_x) = 2a\sigma_x + 2bI_2$, which vanishes only for $a = b = 0$; in the same way $\sigma_z M + M\sigma_z = 2a\sigma_z + 2cI_2$ forces $c = 0$. So $M = dN$ and $M^2 = -d^2 I_2$, never $+I_2$. Three matrices fit because $n = 3$ is odd: the trace lemma fails for the product of all three, which is I_2 with trace 2, so the eight products come in pairs that are equal up to sign (for example $\sigma_x\sigma_z = -N$) and only four of them are independent, $4 = 2^2$, like the seven τ of Section 4.13.

Exercise 2. The code table of Notebook 04a (output of In [18]) begins, for row 0, with -15 in the column x1 and $+14$ in the column x2; row 14 reads -1 (x1), row 15 reads -0 (x1) and -1 (x2). Use only these entries to show that row 0 of $(\gamma^{(x_1)})^2$ is $+u_0$ and that row 0 of $\gamma^{(x_1)}\gamma^{(x_2)}$ is minus row 0 of $\gamma^{(x_2)}\gamma^{(x_1)}$.

Answer. Row 0 of $\gamma^{(x_1)}$: $(\gamma^{(x_1)}v)_0 = -v_{15}$. With $v = \gamma^{(x_1)}u$ and row 15 of $\gamma^{(x_1)}$, $v_{15} = -u_0$, so $(\gamma^{(x_1)}\gamma^{(x_1)}u)_0 = -(-u_0) = +u_0$, as it must be for the space-like x_1. For the products: $(\gamma^{(x_1)}\gamma^{(x_2)}u)_0 = -(\gamma^{(x_2)}u)_{15} = -(-u_1) = +u_1$ (row 15 of $\gamma^{(x_2)}$ is -1), while $(\gamma^{(x_2)}\gamma^{(x_1)}u)_0 = +(\gamma^{(x_1)}u)_{14} = +(-u_1) = -u_1$ (row 14 of $\gamma^{(x_1)}$ is -1). The two differ by a sign: in row 0, the two gammas anticommute.

Exercise 3. How many of the 56 products of degree 3 square to $+I_{16}$, and how many to $-I_{16}$? Compare with figure 3 of Notebook 04c.

Answer. By rule R2 with $k = 3$, $\gamma_A^2 = (-1)^3 \prod_{a\in A}\eta^{aa} I_{16} = -\prod_{a\in A}\eta^{aa} I_{16}$. This is $+I_{16}$ exactly when the product of the three signs is -1, that is when A contains an odd number of time-like directions. One time-like and two space-like directions: $\binom{4}{1}\binom{4}{2} = 4\cdot 6 = 24$ sets; three time-like: $\binom{4}{3} = 4$ sets. So $24 + 4 = 28$ products square to $+I_{16}$ and $56 - 28 = 28$ to $-I_{16}$: the two equal parts (28 red and 28 blue) of the stacked bar at degree 3 in the figure.

Exercise 4. Compute the 4×4 matrix $P \otimes N$ with the index formula, and its square in two ways: with the mixed-product rule, and by following row 0 in the code notation.

Answer. $P \otimes N = \begin{pmatrix} 0 \cdot N & 1 \cdot N \\ 1 \cdot N & 0 \cdot N \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}$. By the mixed-product rule, $(P \otimes N)^2 = P^2 \otimes N^2 = I_2 \otimes (-I_2) = -I_4$. In code notation, row 0 is $+3$ and row 3 is -0, so $((P \otimes N)^2 u)_0 = +((P \otimes N)u)_3 = -u_0$, row 0 of $-I_4$.

Exercise 5. Take $m = 1$, no momentum in x_0, x_1, x_2, x_3, and a wave $e^{ik_{x_5} x_5}$ along the extra time x_5 with the coordinate momentum $k_{x_5} = 1$, at a point where $\sin z = 1/64$ and $b_4 = 1$. Using the frame factor of Section 4.4, find the frame momentum and E^2 (a) when $a_4 = 0$ and (b) when $a_4 = \ln 2$. What happens to the growth rate as the extra times deflate?

Answer. The frame factor of x_5 is $b_4^{1/2} e^{-a_4} \sin^{1/6} z = e^{-a_4}(1/64)^{1/6} = e^{-a_4}/2$, since $b_4 = 1$ and $2^6 = 64$. The frame momentum is the coordinate momentum divided by it: $k_5 = 2e^{a_4}$. (a) $a_4 = 0$: $k_5 = 2$, and $E^2 = m^2 - k_5^2 = 1 - 4 = -3$, so $E = \pm i\sqrt{3}$: the exact example of the Revision record, with the growth rate $\sqrt{3} \approx 1.73$. (b) $a_4 = \ln 2$: $e^{a_4} = 2$, $k_5 = 4$, $E^2 = 1 - 16 = -15$, growth rate $\sqrt{15} \approx 3.87$. As a_4 grows the extra times deflate, the frame momentum grows like e^{a_4}, and the growth rate grows with it. (This is the local plane-wave reading of Section 4.9, with the coefficients held fixed near the point.)

Exercise 6. For which of the pairs (x_1, x_2), (x_1, x_4), (x_5, x_6), (x_4, x_0) does $(2S^{ab})^2$ equal $-I_{16}$, and for which $+I_{16}$? Which are rotation planes and which boost planes? Show also that $S^{ba} = -S^{ab}$.

Answer. $2S^{ab} = \gamma^a \gamma^b$ for $a \neq b$ (Section 4.13), and $(\gamma^a \gamma^b)^2 = -\eta^{aa}\eta^{bb} I_{16}$. (x_1, x_2): both space-like, $\eta^{aa}\eta^{bb} = +1$, square $-I_{16}$, a rotation plane. (x_1, x_4): space-like and time-like, -1, square $+I_{16}$, a boost plane. (x_5, x_6): both time-like, $(-1)(-1) = +1$, square $-I_{16}$, a rotation plane. (x_4, x_0): time-like and space-like, square $+I_{16}$, a boost plane. Finally $S^{ba} = \frac{1}{4}(\gamma^b \gamma^a - \gamma^a \gamma^b) = -\frac{1}{4}(\gamma^a \gamma^b - \gamma^b \gamma^a) = -S^{ab}$.

Exercise 7. Without a computer, find the energies of the plane waves of the flat equation for $m = 3$, $k_0 = 0$, $(k_1, k_2, k_3) = (0, 0, 4)$ and no momentum along the extra times, and how often each occurs.

Answer. $h^2 = (m^2 + k_3^2) I_{16} = (9 + 16) I_{16} = 25 I_{16}$ (Section 4.9), so every eigenvalue is $+5$ or -5. Without extra-time momentum h is Hermitian, and its trace is 0 (every term of h is a multiple of $\gamma^{(x_4)}$ or of $\gamma^{(x_4)}\gamma^{(x_a)}$ with $a \neq x_4$, which have trace 0). With n_+ eigenvalues $+5$ and n_- eigenvalues -5: $n_+ + n_- = 16$ and $5n_+ - 5n_- = 0$, so $E = +5$ and $E = -5$ occur eight times each.

5 The matrices C, Γ and B, the groups Pin(4,4) and Spin(4,4), and the charge-conjugation matrices

Chapter 4 built the author's eight real gamma matrices, one 16×16 matrix for each of the eight directions of the author's universe, and proved that they obey the Clifford relation. This chapter builds from them everything else that a field with 16 components needs before its equations can be written down: the charge matrix C (which turns two spinors into a number), the chirality Γ (which cuts the 16 components into two halves of 8), the matrix B (whose bilinear is the charge

density), the groups Pin(4,4) and Spin(4,4) of spinor transformations with their generators S^{ab}, and the two charge-conjugation matrices $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$. It proves the author's statement that the 16 components carry an irreducible representation of Pin(4,4) that splits under Spin(4,4) into two inequivalent halves, and it answers exactly the question which group the scaled commutators S^{ab} generate.

5.1 What this chapter does

A spinor field Ψ attaches 16 numbers $\Psi_1, \ldots, \Psi_{16}$ to every point of spacetime. Its field equation (Chapter 7) multiplies Ψ by the gamma matrices. Four further questions must be answered before the equation can be used, and each needs one of the matrices of this chapter.

- How do we make a single number out of a spinor, a number that does not change when the eight directions are turned into each other? The answer is the **bilinear** $\Psi^\dagger C \Psi$ with the charge matrix C (Sections 5.4 and 5.18).
- Which parts of a spinor stay separate under every turning of the directions? The two **chiral halves**, components 1 to 8 and 9 to 16, picked out by the chirality Γ (Sections 5.5 and 5.13).
- What is the **charge density** of a spinor field, the quantity whose total stays constant in time when no charge flows in or out through the edges of space? It is $\Psi^\dagger B \Psi$ with the matrix B (Section 5.6).
- What exchanges particles and antiparticles? A **charge-conjugation matrix**. Because the author's gammas are real, plain complex conjugation does nothing to a real field and cannot exchange anything; the exchange must be made by a matrix. Section 5.28 defines a charge-conjugation matrix by a condition that it must obey together with every gamma, and proves that there are exactly two such matrices, up to a factor, $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$ (Sections 5.28 and 5.29). For the quantised field only one of the two, up to a phase factor, keeps the basic rule of the quantum theory, and it reverses the mass (Section 5.34). Section 5.39 states what these exact maps do and do not say about matter and antimatter in the universe.

Between these questions stands the group theory: the groups Pin(4,4) and Spin(4,4) that act on spinors, the words irreducible and inequivalent, and what the scaled commutators $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b]$ generate. Everything is introduced from zero: a reader who knows school algebra and the derivative of one-variable functions can follow every line.

The chapter has six worked examples, each a complete Jupyter notebook:

- Notebook 05a: the matrices C, Γ and B and every property that the Revision record states about them (26 checks, six figures);
- Notebook 05b: the commutants, which prove that Pin(4,4) acts irreducibly on the 16 components and that Spin(4,4) splits them into two inequivalent halves (17 checks, five figures);
- Notebook 05d: the spin transformations, rotations and boosts, the double cover and the forms kept by them (20 checks, six figures);
- Notebook 05f: what the scaled commutators generate (24 checks, six figures);

- Notebook 05c: the charge-conjugation matrices (20 checks, nine figures);
- Notebook 05e: the conjugation of the quantised field, computed on a space of $2^{16} = 65536$ quantum states (18 checks, eight figures).

They appear in this order, a, b, d, f, c, e: first the matrices, then the group theory, then charge conjugation. Every notebook is complete in itself, so you may run them in any order.

Notation. The author's coordinates are written $x0, \ldots, x7$ (Chapter 0 writes them $x_0, \ldots, x_7$): $x0$ is the hidden space direction; $x1$, $x2$, $x3$ are ordinary 3-space, which inflates; $x4$ is the time; $x5$, $x6$, $x7$ are the three extra times, which deflate exponentially. The gamma matrix of the direction $x4$ is written $\gamma^{(x4)}$, and so on. Letters a, b, c, d, e stand for any of the eight directions. The flat metric of the frame is

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

in the order $x0, \ldots, x7$; its entry for the direction a is written η_{aa} (or η^{aa}, which is the same number). The directions with $\eta_{aa} = +1$ ($x0$, $x1$, $x2$, $x3$) are called **space-like**, those with $\eta_{aa} = -1$ ($x4$, $x5$, $x6$, $x7$) **time-like**. The symbol 1 also stands for the 16×16 identity matrix, and 1_8 for the 8×8 one.

5.2 The eight real gamma matrices

The gamma matrices are eight real 16×16 matrices $\gamma^{(x0)}, \ldots, \gamma^{(x7)}$. Chapter 4 built them from the author's formulas (his matrices T16, with $\gamma^{(xk)} = \mathrm{T16}[k]$ for $k = 0, \ldots, 7$) and proved the **Clifford relation**

$$\gamma^a \gamma^b + \gamma^b \gamma^a = 2\eta^{ab}\, 1 \qquad \text{for all } a, b,$$

where η^{ab} is η_{aa} when $a = b$ and 0 when $a \neq b$. Written out, the relation says two things. For $a = b$: $\gamma^a \gamma^a = \eta_{aa} 1$, so a space-like gamma squares to $+1$ and a time-like gamma to -1. For $a \neq b$: $\gamma^a \gamma^b = -\gamma^b \gamma^a$, so two different gammas **anticommute** (exchanging them costs a sign). The Revision record stores the eight matrices in the file `Revision/algebra/gammas.json`, and two independent programs have checked them: `Revision/algebra/reports/python-algebra.json` (35 of 35 checks passed) and `Revision/algebra/reports/wolfram-algebra.json` (45 of 45 checks passed).

Every gamma is a **signed permutation matrix**: in each row exactly one entry is nonzero, and it is $+1$ or -1; the same holds in each column. Such a matrix is described completely by saying, for each row, in which column its nonzero entry stands and with which sign. The two following tables do this for all eight gammas, first the four space-like ones and then the four time-like ones. The entry $+9$ in row 1 of the column $\gamma^{(x0)}$ means: the matrix $\gamma^{(x0)}$ has the entry $+1$ in row 1 and column 9, and zeros in the other fifteen places of row 1. The tables are read off the record `Revision/algebra/gammas.json`.

row	$\gamma^{(x0)}$	$\gamma^{(x1)}$	$\gamma^{(x2)}$	$\gamma^{(x3)}$
1	+9	−16	+15	−14
2	+10	−15	−16	+13
3	+11	+14	−13	−16
4	+12	+13	+14	+15
5	+13	−12	+11	−10
6	+14	−11	−12	+9
7	+15	+10	−9	−12
8	+16	+9	+10	+11
9	+1	+8	−7	+6
10	+2	+7	+8	−5
11	+3	−6	+5	+8
12	+4	−5	−6	−7
13	+5	+4	−3	+2
14	+6	+3	+4	−1
15	+7	−2	+1	+4
16	+8	−1	−2	−3

The four time-like gammas, read in the same way:

row	$\gamma^{(x4)}$	$\gamma^{(x5)}$	$\gamma^{(x6)}$	$\gamma^{(x7)}$
1	−14	+15	+16	+9
2	+13	+16	−15	+10
3	+16	−13	+14	+11
4	−15	−14	−13	+12
5	+10	−11	−12	−13
6	−9	−12	+11	−14
7	−12	+9	−10	−15
8	+11	+10	+9	−16
9	+6	−7	−8	−1
10	−5	−8	+7	−2
11	−8	+5	−6	−3
12	+7	+6	+5	−4
13	−2	+3	+4	+5
14	+1	+4	−3	+6
15	+4	−1	+2	+7
16	−3	−2	−1	+8

How to multiply two signed permutation matrices. Let M have in row r the entry s (a sign) in column k, and let N have in row k the entry t in column c. The entry of MN in row r and column q is $\sum_j M_{rj}N_{jq}$; only $j = k$ contributes, and N_{kq} is nonzero only for $q = c$. So MN has in row r the single entry st in column c: follow the row number through the two columns of the table and multiply the signs. For example, for $\gamma^{(x4)}\gamma^{(x4)}$: row 1 of $\gamma^{(x4)}$ points to column 14 with the sign −, and row 14 of $\gamma^{(x4)}$ points to column 1 with the sign +; so row 1 of $\gamma^{(x4)}\gamma^{(x4)}$ has the entry $(-1)(+1) = -1$ in column 1, as $\gamma^{(x4)}\gamma^{(x4)} = \eta_{x4\,x4}1 = -1$ demands. For $\gamma^{(x0)}\gamma^{(x0)}$: row 1 points to column 9 with +, row 9 points back to column 1 with +; the product has +1 on the diagonal.

Symmetric and antisymmetric. The transpose M^T of a matrix exchanges rows and columns, $(M^T)_{rc} = M_{cr}$. The table shows that $\gamma^{(x1)}$ has −1 in row 1, column 16, and also −1 in row 16, column 1: the two entries mirror each other with the same sign. In fact the four space-like gammas

are **symmetric** ($M^T = M$) and the four time-like ones are **antisymmetric** ($M^T = -M$; for example $\gamma^{(x4)}$ has -1 in row 1, column 14 and $+1$ in row 14, column 1). In one formula:

$$(\gamma^a)^T = \eta_{aa}\,\gamma^a.$$

The statuses of these facts are listed in the next table. Here and in every later status table, the last column names the report file of the Revision record and the names of its checks; a report is a file in which a program has recorded every check with its name, its verdict and a detail text. The two reports `python-algebra.json` and `wolfram-algebra.json` lie in the folder `Revision/algebra/reports`.

statement	status	where it is verified
the Clifford relation for all 64 pairs of directions	PROVED (exact integer arithmetic)	`python-algebra.json`, checks `clifford_relation` and `clifford_relation_sympy`; `wolfram-algebra.json`, check `Clifford_relation`
every gamma is real and a signed permutation matrix	PROVED	`python-algebra.json`, check `reality_signed_permutations`; `wolfram-algebra.json`, checks `reality` and `signed_permutation_matrices`
$(\gamma^a)^T = \eta_{aa}\gamma^a$	PROVED	`python-algebra.json` and `wolfram-algebra.json`, check `symmetry_pattern`

Notebook 05a checks all three facts again. Everything in Sections 5.3 to 5.6 follows from the Clifford relation and the symmetry pattern alone.

5.3 Six rules for products of gammas

A **product of different gammas** is a product $P = \gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ of k gammas of k different directions $a_1, \ldots, a_k$; k is its **degree**. There are $2^8 = 256$ of them if we take the directions in the order $x0, \ldots, x7$ and count the empty product 1 (each direction is either in the product or not). The six rules below are used again and again in this chapter.

Rule 1 (moving a gamma through a product). Take a gamma γ^e and the product P. Move γ^e from the left of P to its right, one factor at a time. Passing a factor γ^{a_j} with $a_j \neq e$ costs a sign, because

$$\gamma^e\gamma^{a_j} = -\gamma^{a_j}\gamma^e \qquad (a_j \neq e),$$

which is the Clifford relation for two different directions. Passing the factor γ^e itself costs nothing, because a matrix commutes with itself. So the sign is -1 to the power of the number of factors different from e:

$$\gamma^e P = (-1)^{k-1}\, P\gamma^e \quad \text{if } e \text{ is one of the } k \text{ factors}, \qquad \gamma^e P = (-1)^k\, P\gamma^e \quad \text{if it is not.}$$

Rule 2 (the square of a product). Write $P = \gamma^{a_1} P'$ with $P' = \gamma^{a_2} \cdots \gamma^{a_k}$. Then

$$PP = \gamma^{a_1} P' \gamma^{a_1} P'.$$

Move the second γ^{a_1} to the left through P'; P' has $k-1$ factors, all different from a_1, so Rule 1 (read from right to left) gives

$$PP = (-1)^{k-1} \gamma^{a_1}\gamma^{a_1} P'P' = (-1)^{k-1} \eta_{a_1 a_1}\, P'P',$$

where the second step is the Clifford relation $\gamma^{a_1}\gamma^{a_1} = \eta_{a_1 a_1} 1$. The product $P'P'$ is the square of a product of $k-1$ different gammas, so the same step applies to it, with $k-2$ factors to pass, and so on down to the empty product. Collecting the signs:

$$PP = (-1)^{(k-1)+(k-2)+\cdots+1+0}\ \eta_{a_1 a_1}\eta_{a_2 a_2}\cdots\eta_{a_k a_k}\, 1 = (-1)^{k(k-1)/2}\ \eta_{a_1 a_1}\cdots\eta_{a_k a_k}\, 1,$$

where the last step is the sum of the numbers $0, 1, \ldots, k-1$, which is $k(k-1)/2$ (write the sum forwards and backwards and add: k pairs, each adding up to $k-1$).

Rule 3 (reversing a product). $\gamma^{a_k}\cdots\gamma^{a_2}\gamma^{a_1} = (-1)^{k(k-1)/2}\,\gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$. Proof: in the reversed product, move γ^{a_1} from the last place to the first; it passes $k-1$ different factors, each costing a sign. Then move γ^{a_2} to the second place; it passes $k-2$ factors. Continuing, the total number of sign changes is $(k-1)+(k-2)+\cdots+0 = k(k-1)/2$.

Rule 4 (the transpose of a product). The transpose of a product is the product of the transposes in the reverse order, $(MN)^T = N^T M^T$. With the symmetry pattern $(\gamma^a)^T = \eta_{aa}\gamma^a$ and Rule 3:

$$P^T = (\gamma^{a_k})^T \cdots (\gamma^{a_1})^T = \eta_{a_1 a_1}\cdots\eta_{a_k a_k}\ \gamma^{a_k}\cdots\gamma^{a_1} = (-1)^{k(k-1)/2}\ \eta_{a_1 a_1}\cdots\eta_{a_k a_k}\ P.$$

Rule 5 (the trace of a product is zero). The **trace** $\operatorname{tr} M$ of a square matrix is the sum of its diagonal entries; for two square matrices $\operatorname{tr}(MN) = \operatorname{tr}(NM)$, because both are $\sum_{r,c} M_{rc} N_{cr}$. Claim: every product P of $k \geq 1$ different gammas has $\operatorname{tr} P = 0$. Proof: first find a gamma γ^e that anticommutes with P. If k is even, take e to be one of the factors: by Rule 1 the sign is $(-1)^{k-1} = -1$. If k is odd, then $k \leq 7$, so at least one of the eight directions is not a factor; take e to be such a direction: the sign is $(-1)^k = -1$. Now, using $\gamma^e\gamma^e = \eta_{ee} 1$ and $\eta_{ee}\eta_{ee} = 1$,

$$\operatorname{tr} P = \eta_{ee} \operatorname{tr}(\gamma^e\gamma^e P) = \eta_{ee} \operatorname{tr}(\gamma^e P \gamma^e) = -\eta_{ee} \operatorname{tr}(\gamma^e\gamma^e P) = -\operatorname{tr} P.$$

The first step inserts $\eta_{ee}\gamma^e\gamma^e = 1$; the second is $\operatorname{tr}(MN) = \operatorname{tr}(NM)$ with $M = \gamma^e$ and $N = \gamma^e P$; the third uses $P\gamma^e = -\gamma^e P$; the fourth undoes the first. A number equal to minus itself is 0.

Rule 6 (counting eigenvalues). An **eigenvalue** of a square matrix M is a number λ for which some column $v \neq 0$ has $Mv = \lambda v$. A 16×16 matrix has 16 eigenvalues when each is counted as often as it occurs as a root of the polynomial $\det(\lambda 1 - M)$ (its **multiplicity**), and the trace is their sum. Claim: if $MM = 1$ and $\operatorname{tr} M = 0$, then M has the eigenvalue $+1$ eight times and -1 eight times.

Proof: if $Mv = \lambda v$, then $v = MMv = M(\lambda v) = \lambda^2 v$, so $\lambda^2 = 1$ and $\lambda = \pm 1$. With n_+ eigenvalues $+1$ and n_- eigenvalues -1: $n_+ + n_- = 16$ and $n_+ - n_- = \operatorname{tr} M = 0$, so $n_+ = n_- = 8$. In the same way, if $MM = -1$ and $\operatorname{tr} M = 0$, then $\lambda^2 = -1$, $\lambda = \pm i$, and $i(n_+ - n_-) = 0$ gives eight $+i$ and eight $-i$. In both cases the **determinant**, the product of the 16 eigenvalues, is $(+1)^8(-1)^8 = 1$ or $i^8(-i)^8 = 1$.

Applied to the gammas themselves: a space-like gamma has $\gamma\gamma = +1$ and trace 0 (Rule 5 with $k = 1$), so eight eigenvalues $+1$ and eight -1; a time-like gamma has eight $+i$ and eight $-i$; every gamma has determinant $+1$. Status: PROVED (by the rules above). Notebook 05a checks the squaring rule on all 255 products of degree 1 to 8 and counts the eigenvalues; Notebook 05d computes the eight determinants exactly.

5.4 The charge matrix C and the Dirac adjoint

Definition. The **charge matrix** is the product of the four space-like gammas,

$$C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}.$$

The author calls it sigma16. It is used to make numbers out of spinors: the **Dirac adjoint** of a column Ψ is the row $\bar{\Psi} = \Psi^\dagger C$, where $\Psi^\dagger$ is the row of the complex conjugates of the components of Ψ, and the **scalar** of the field is

$$S = \bar{\Psi}\Psi = \Psi^\dagger C \Psi = \sum_{r,c} \Psi_r^* C_{rc} \Psi_c.$$

Section 5.18 proves that S does not change when the directions are turned by any element of Spin(4,4); this is why C, and not the identity matrix, stands between $\Psi^\dagger$ and Ψ. Here are its properties, each derived from Section 5.3.

(C1) How C moves past a gamma: $C\gamma^a = -\eta_{aa}\gamma^a C$**.** C is a product of $k = 4$ different gammas. If a is space-like, γ^a is one of its factors, and Rule 1 gives $\gamma^a C = (-1)^3 C\gamma^a = -C\gamma^a$. If a is time-like, it is not a factor, and Rule 1 gives $\gamma^a C = (-1)^4 C\gamma^a = C\gamma^a$. Both cases read $\gamma^a C = -\eta_{aa} C\gamma^a$. Multiplying this by $-\eta_{aa}$ and using $\eta_{aa}\eta_{aa} = 1$ gives the claim. So C anticommutes with the four space-like gammas and commutes with the four time-like ones.

(C2) C is symmetric. Rule 4 with $k = 4$ and four space-like factors: $C^T = (-1)^6(+1)^4\, C = C$.

(C3) $CC = 1$**.** Rule 2 with $k = 4$: $CC = (-1)^6(+1)^4\, 1 = 1$. So C is its own inverse, $C^{-1} = C$.

(C4) Every $C\gamma^a$ **is antisymmetric.** Line by line:

$$(C\gamma^a)^T = (\gamma^a)^T C^T = \eta_{aa}\gamma^a C = \eta_{aa}(-\eta_{aa})\, C\gamma^a = -C\gamma^a.$$

The first step is $(MN)^T = N^T M^T$; the second uses the symmetry pattern and (C2); the third is (C1) in the form $\gamma^a C = -\eta_{aa} C\gamma^a$; the fourth is $\eta_{aa}\eta_{aa} = 1$.

(C5) $C\gamma^a C^{-1} = -(\gamma^a)^T$**.** With $C^{-1} = C$ from (C3):

$$C\gamma^a C = (-\eta_{aa}\gamma^a C)\, C = -\eta_{aa}\gamma^a\, CC = -\eta_{aa}\gamma^a = -(\gamma^a)^T.$$

The first step is (C1), the second regroups the product, the third is (C3), the fourth is the symmetry pattern.

(C6) C has signature (8, 8). By Rule 5, $\operatorname{tr} C = 0$; with $CC = 1$, Rule 6 gives eight eigenvalues $+1$ and eight -1. For a real symmetric matrix the pair (number of positive eigenvalues, number of negative eigenvalues) is called its **signature**; C has signature $(8, 8)$. This means that the **quadratic form** $u^T C u = \sum_{r,c} u_r C_{rc} u_c$ of a real column u takes both signs. Example (Notebook 05a, section 7): the table of Section 5.6 shows $C_{1,5} = C_{5,1} = -1$. For $u(t) = \cos t\, e_1 + \sin t\, e_5$, where e_r is the column with 1 in row r and 0 elsewhere, only these two entries meet two nonzero components, and

$$u^T C u = 2 \cos t \, \sin t \, C_{1,5} = -\sin 2t,$$

by the double-angle formula $2 \sin t \cos t = \sin 2t$. At $t = \pi/4$ the form is -1; with the components 9 and 13, where $C_{9,13} = +1$, it is $+1$. The ordinary squared length $u^T u = \cos^2 t + \sin^2 t = 1$ never changes sign; the form of C does.

(C7) The shape of C. The table of Section 5.6 shows $C = \operatorname{diag}(-\sigma, \sigma)$, the block matrix with $-\sigma$ in the top left, $+\sigma$ in the bottom right and zeros elsewhere, where σ is the author's 8×8 matrix with the 4×4 identity in its two off-diagonal blocks:

$$\sigma = \begin{pmatrix} 0 & 1_4 \\ 1_4 & 0 \end{pmatrix}.$$

Consequences for the bilinears. The **currents** of the field are $J^a = -i\bar{\Psi}\gamma^a\Psi = \Psi^\dagger(-iC\gamma^a)\Psi$. By (C4), $C\gamma^a$ is real and antisymmetric, so the matrix $-iC\gamma^a$ is **Hermitian** (equal to its conjugate transpose): $(-iC\gamma^a)^\dagger = (+i)(C\gamma^a)^T = -iC\gamma^a$. A Hermitian matrix K gives a real number $\Psi^\dagger K \Psi$ for every complex column Ψ of ordinary numbers (its complex conjugate is $\Psi^\dagger K^\dagger \Psi$, the same number). C is real and symmetric, hence Hermitian too, so S and the eight currents are real.

5.5 The chirality and the two halves

Definition. The **chirality** is the product of all eight gammas in the author's order,

$$\Gamma = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}\gamma^{(x4)}\gamma^{(x5)}\gamma^{(x6)}\gamma^{(x7)}.$$

(The author calls it T16[8]; the label 8 is a name, not a ninth direction.) Its properties:

(X1) $\Gamma\Gamma = 1$**.** Rule 2 with $k = 8$, four space-like and four time-like factors: $\Gamma\Gamma = (-1)^{28}(+1)^4(-1)^4\,1 = 1$.

(X2) Γ **anticommutes with every gamma.** Every direction is one of the eight factors, so Rule 1 gives $\gamma^a\Gamma = (-1)^7\Gamma\gamma^a = -\Gamma\gamma^a$.

(X3) Γ **commutes with every product of an even number of gammas and anticommutes with every product of an odd number.** Moving Γ through a product of j gammas (different or not) passes j factors, each costing a sign by (X2): $\Gamma E = (-1)^j E\Gamma$. A product of an even number of gammas is called **even**, one of an odd number **odd**.

(X4) $\Gamma = C\gamma^{(x4)}\gamma^{(x5)}\gamma^{(x6)}\gamma^{(x7)}$**.** The first four factors of Γ are C.

(X5) $C\Gamma = \Gamma C$**.** C is even (four factors); use (X3).

(X6) Γ **is symmetric.** Rule 4 with $k = 8$: $\Gamma^T = (-1)^{28}(+1)^4(-1)^4\,\Gamma = \Gamma$.

(X7) $\Gamma^T C\Gamma = C$**.** Line by line: $\Gamma^T C\Gamma = \Gamma C\Gamma$ by (X6); $= C\Gamma\Gamma$ by (X5); $= C$ by (X1).

(X8) $\Gamma^T C\gamma^a\Gamma = -C\gamma^a$ **for every** a**.** Line by line: $\Gamma^T C\gamma^a\Gamma = \Gamma C\gamma^a\Gamma$ by (X6); $= C\Gamma\gamma^a\Gamma$ by (X5); $= -C\gamma^a\Gamma\Gamma$ by (X2); $= -C\gamma^a$ by (X1).

(X9) $\Gamma = \mathrm{diag}(-1_8, 1_8)$**.** For the author's gammas the product is diagonal: -1 on the first eight diagonal places and $+1$ on the last eight (the table of Section 5.6, column Γ: row r points to column r, with the sign $-$ for $r \le 8$). This agrees with Rule 6: eight eigenvalues -1 and eight $+1$.

The chiral projectors. A **projector** is a matrix with $PP = P$. Put

$$P_- = \tfrac{1}{2}(1 - \Gamma), \qquad P_+ = \tfrac{1}{2}(1 + \Gamma).$$

Then, multiplying out and using (X1),

$$P_-P_- = \tfrac{1}{4}(1 - 2\Gamma + \Gamma\Gamma) = \tfrac{1}{4}(2 - 2\Gamma) = P_-,$$

and in the same way $P_+P_+ = P_+$, while $P_-P_+ = \frac{1}{4}(1 - \Gamma\Gamma) = 0$ and $P_- + P_+ = 1$. By (X9), $P_- = \mathrm{diag}(1_8, 0)$ keeps the components 1 to 8 of a column and sets the others to zero, and $P_+ = \mathrm{diag}(0, 1_8)$ keeps the components 9 to 16. These are the two **chiral halves**: on the first half $\Gamma = -1$, on the second $\Gamma = +1$.

Every gamma exchanges the halves. Using (X2),

$$\gamma^a P_- = \tfrac{1}{2}(\gamma^a - \gamma^a\Gamma) = \tfrac{1}{2}(\gamma^a + \Gamma\gamma^a) = P_+\gamma^a.$$

So if a column Ψ lives in the first half ($P_-\Psi = \Psi$), then $\gamma^a\Psi = \gamma^a P_-\Psi = P_+\gamma^a\Psi$ lives in the second half, and the same with the halves exchanged. In the table of Section 5.2 this is visible: in every gamma, rows 1 to 8 point to columns 9 to 16 and rows 9 to 16 to columns 1 to 8.

The block rule. Cut a 16×16 matrix into four 8×8 blocks, $M = \begin{pmatrix} W & X \\ Y & Z \end{pmatrix}$. With $\Gamma = \mathrm{diag}(-1_8, 1_8)$, multiplying from the left changes the sign of the top rows and from the right the sign of the left columns:

$$\Gamma M = \begin{pmatrix} -W & -X \\ Y & Z \end{pmatrix}, \qquad M\Gamma = \begin{pmatrix} -W & X \\ -Y & Z \end{pmatrix}.$$

So M commutes with Γ exactly when $X = Y = 0$ (**block diagonal**), and anticommutes with it exactly when $W = Z = 0$ (**block off-diagonal**). With (X3): every even product of gammas is block diagonal and every odd one block off-diagonal.

Why (X7) and (X8) matter. Map a field Ψ to $\Gamma\Psi$. Because Γ is real, $(\Gamma\Psi)^\dagger = \Psi^\dagger\Gamma^T$, and so

$$(\Gamma\Psi)^\dagger C(\Gamma\Psi) = \Psi^\dagger\Gamma^T C\Gamma\Psi = \Psi^\dagger C\Psi,$$

by (X7): the scalar S is unchanged. By (X8) every bilinear $\Psi^\dagger C\gamma^a\Psi$ changes its sign, and so does every $\Psi^\dagger C\gamma^a E\Psi$ with an even product E (move Γ through E first, which costs nothing). The kinetic term of the Lagrangian of Chapter 7 is of this form, so the map $\Psi \to \Gamma\Psi$ keeps the mass term and reverses the kinetic term. These matrix identities are the input of the pairing theorem T1, which Chapter 18 proves: the map Γ carries the solutions with the parameters (m, λ) to the solutions with $(-m, -\lambda)$. T1 is an exact map between two sets of solutions; it does not say that anything is created (Chapter 20).

5.6 The matrix B and the charge density

Definition. $B = -i\,C\gamma^{(x4)} = -i\,\gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}\gamma^{(x4)}$, where i is the imaginary unit ($i^2 = -1$).

(B1) B is purely imaginary. $C\gamma^{(x4)}$ is a product of real matrices, so it is real, and B is $-i$ times it.

(B2) B is Hermitian. The conjugate transpose of B conjugates the number $-i$ to $+i$ and transposes the real matrix:

$$B^\dagger = (+i)\,(C\gamma^{(x4)})^T = (+i)(-C\gamma^{(x4)}) = -i\,C\gamma^{(x4)} = B,$$

where the second step is (C4) for $a = x4$.

(B3) $BB = 1$. First $BB = (-i)^2\,(C\gamma^{(x4)})(C\gamma^{(x4)}) = -(C\gamma^{(x4)})^2$. The matrix $C\gamma^{(x4)}$ is the product of the five different gammas of $x0, x1, x2, x3, x4$, four space-like and one time-like, so Rule 2 gives $(C\gamma^{(x4)})^2 = (-1)^{10}(+1)^4(-1)\,1 = -1$. Hence $BB = -(-1) = 1$.

(B4) B has signature (8, 8). By Rule 5 (with $k = 5$) $\operatorname{tr} B = 0$, and with $BB = 1$ Rule 6 gives eight eigenvalues $+1$ and eight -1; the characteristic polynomial is $\det(\lambda 1 - B) = (\lambda - 1)^8(\lambda + 1)^8$. As B is Hermitian, the number $\Psi^\dagger B\Psi$ is real for every complex column, and it takes both signs.

(B5) B commutes with five gammas and anticommutes with three. Rule 1 with the five factors $x0, x1, x2, x3, x4$: a gamma among them passes four others, sign $(-1)^4 = +1$; a gamma not among them ($x5$, $x6$, $x7$) passes five, sign $(-1)^5 = -1$. The number $-i$ commutes with every matrix. So B commutes with $\gamma^{(x0)}, \gamma^{(x1)}, \gamma^{(x2)}, \gamma^{(x3)}, \gamma^{(x4)}$ and anticommutes with the gammas of the three extra times.

What B is for. The time component of the current of Section 5.4 is

$$J^{(x4)} = \Psi^\dagger(-iC\gamma^{(x4)})\Psi = \Psi^\dagger B\Psi,$$

the **charge density** of the field. The Revision record proves a **local conservation law**: for every solution of the field equation,

$$\sum_\mu \partial_\mu(\sqrt{|g|}\, J^\mu) = 0 \qquad \text{at every point,}$$

where ∂_μ is the partial derivative along the coordinate μ (the sum runs over $x0, \ldots, x7$), $z = 6Hx0$, $\sqrt{|g|} = b_4^{3/2}\cos z$ is the volume factor of the author's metric (Chapter 3), and $J^\mu = -i\bar{\Psi}\gamma^\mu\Psi$ is the current built with the gammas γ^μ of the curved space (Section 5.28 and Chapter 6; for the time $\gamma^{x4} = \gamma^{(x4)}$, because $g_{44} = -1$, so $J^{x4} = \Psi^\dagger B\Psi$). The record checks this law for a general $b_4(x4)$ (check `u1_noether_matrix_identity_b4` of `Revision/theory/reports/python-field-theory-b4.json`) and, independently, at $b_4 = 1$, where $\sqrt{|g|} = \cos z$ (the lead check `u1_noether_matrix_identity`). The backgrounds of this book have $b_4 = 1$ (Chapter 3, Section 3.8), and the rest of this section writes $\cos z$; for a general b_4, which depends on $x4$ only, the factor $b_4^{3/2}$ multiplies the total charge below at each time. The **total charge** is the integral of the charge density over the seven directions other than the time,

$$Q = \int \cos z\ \Psi^\dagger B\Psi\ d^7x.$$

Line by line: the derivative of Q with respect to the time $x4$ is the integral of $\partial_{x4}(\cos z\, J^{x4})$; by the local law this equals minus the integral of the seven other terms $\partial_\mu(\cos z\, J^\mu)$, $\mu \neq x4$; and the integral of a derivative along one direction is the difference of the values at the two ends of that direction (the fundamental theorem of calculus). So $dQ/dx4$ equals minus the **flux** of the current through the boundary of the seven other directions. Hence Q does not change in time **for every solution whose current flux through that boundary vanishes**. The condition is needed: the local law alone does not make the flux zero. The seven directions are the unbounded directions of 3-space and of the extra times and the hidden interval $0 < z < \pi/2$, which has two ends. At the end $z \to 0$, the **tip**, the metric is singular ($g_{00} = \cot^2 z$ grows without bound). The other end, $z = \pi/2$, is the **brane** (the edge of the hidden direction, at a finite distance, where $g_{00} = \cot^2 z = 0$). The part of the flux that leaves through these two ends is $\cos z\, J^{x0}$ at $z = \pi/2$ minus its value at $z \to 0$, added up over the six other directions. The Revision record states that this boundary term vanishes at the tip $z \to 0$ but not, in general, at the brane $z = \pi/2$ (`Revision/theory/reports/python-scope.json`, check `good_sector_hermiticity_up_to_the_brane_flux`), and the record's check of the local law says the same: it proves the local law only, and the constancy of Q is not established by it. Chapter 18 (Section 18.21) derives a family of exact solutions, the fields that depend only on the time. Some of them, for example the one of Notebook 18c, send charge through the brane: for these fields the flow $\cos z\, J^{x0}$ at the brane equals a number q_0 that changes in time, and Notebook 18c finds it between -0.3454 and 0.3454, so that the charge of a region that spans the whole hidden interval changes in time. Chapter 10 (Sections 10.27 and 10.28) shows another exact solution whose charge grows. Not every member of the family of Section 18.21 sends charge through the brane. That section writes the field equation of these fields as $d\Psi/dx4 = M\Psi$ with a constant matrix M whose square, in the oscillating case of that section, is $-w^2$ times the unit

matrix ($w > 0$ a number), and its solution in that case as $\Psi(x4) = \cos(wx4)\,\Psi(0) + \frac{\sin(wx4)}{w}\,M\Psi(0)$. Take any column v for which $\chi = \frac{1}{2}(v - \frac{i}{w}Mv)$ is not zero, and start from $\Psi(0) = \chi$. Line by line: $M\chi = \frac{1}{2}(Mv - \frac{i}{w}M^2v) = \frac{1}{2}(Mv + iwv)$, because $M^2 = -w^2$ and $-\frac{i}{w}(-w^2) = iw$; and $iw\chi = \frac{1}{2}(iwv - \frac{i\cdot i\,w}{w}Mv) = \frac{1}{2}(iwv + Mv)$, because $i \cdot i = -1$; the two agree, so $M\chi = iw\chi$; inserting $M\chi = iw\chi$ into the solution gives $\Psi(x4) = \big(\cos(wx4) + i\sin(wx4)\big)\chi = e^{iwx4}\chi$, a **stationary** solution (a fixed column times a phase factor); its charge density is $\Psi^\dagger B\Psi = e^{-iwx4}e^{iwx4}\,\chi^\dagger B\chi = \chi^\dagger B\chi$, the same at every time; the field depends only on $x4$, so in the local law every derivative except those along $x4$ and $x0$ is zero, and the law reads $\partial_{x4}(\cos z\, J^{x4}) = -\partial_{x0}(\cos z\, J^{x0})$; the left side is zero, because $\cos z$ does not depend on $x4$ and J^{x4} does not change in time; so $\cos z\, J^{x0}$ has the same value at every point of the hidden interval; it is zero at the tip (the record's boundary term vanishes there), hence it is zero at the brane. So a constant total charge needs a **no-flux condition** at the brane, $\cos z\, J^{x0} = 0$ at $z = \pi/2$, which holds for some solutions (the stationary ones above) and fails for others (the one of Notebook 18c). No equation of the Revision record or of this book derives it for every solution, and the field equations and the quantisation of the record impose no condition at the brane (OPEN). The Kohn-Sham model of Chapter 14 ASSUMES one: a **Z2 mirror** at the brane (the hidden interval is glued at the brane to a mirror copy of itself), whose two conditions make the current along the hidden direction zero there (`Revision/kohn_sham/ks-theory.json`, entry `boundaryConditions.brane`, status ASSUMED). Wherever a constant total charge is used, this condition is ASSUMED. The status table at the end of this section names the checks; Chapter 21 derives the identity and the boundary terms. Because B has eight positive and eight negative eigenvalues, the charge density can be positive or negative: the field can carry charge of both signs. In the quantum theory B is the matrix of the canonical anticommutator, and its indefinite signature forces an indefinite (Krein) inner product (Section 5.34 and Chapter 10).

The matrices C, Γ, B and ΓC in one table. Each is a signed permutation matrix (for B, after division by i); the table is read like the one of Section 5.2. C, Γ and B are stored in the record `Revision/algebra/gammas.json`; ΓC (the charge-conjugation matrix $\mathcal{C}_-$ of Section 5.28) is C with the signs of rows 1 to 8 reversed, as Notebook 05c computes.

16	+12	+16	−7	+12

Reading the table: C maps row 1 to column 5 with the sign −, so $C_{1,5} = -1$, the entry used in (C6); B/i has +10 in row 1 and −1 in row 10, so $B_{1,10} = +i$ and $B_{10,1} = -i = (B_{1,10})^*$, as a Hermitian

matrix requires; ΓC has $+\sigma$ in both diagonal blocks.

statement	status	where it is verified
(B1): $B = -iC\gamma^{(x4)}$ is purely imaginary	PROVED	`wolfram-algebra.json`, checks `B_definition` and `B_purely_imaginary`
(B2) to (B4): B is Hermitian, $BB = 1$, $\mathrm{tr}\, B = 0$, characteristic polynomial $(\lambda-1)^8(\lambda+1)^8$	PROVED	`python-algebra.json`, check `B_hermitian_involution_signature`; `wolfram-algebra.json`, checks `B_Hermitian`, `B_squared_identity` and `B_signature_8_8`
(B5): the commutation signs of B	PROVED	`python-algebra.json`, check `B_gamma_relations`
the local law $\sum_\mu \partial_\mu(\sqrt{\lvert g\rvert}\, J^\mu) = 0$ for every solution, with $\sqrt{\lvert g\rvert} = b_4^{3/2}\cos z$ ($\cos z$ at $b_4 = 1$)	PROVED in the record (derived in Chapter 21)	`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity` ($b_4 = 1$); `Revision/theory/reports/python-field-theory-b4.json`, check `u1_noether_matrix_identity_b4` (general b_4)
the total charge Q is constant in time for every solution whose current flux through the boundary of the seven other directions vanishes	PROVED (a conditional statement, from the local law, above; the boundary terms in Chapter 21)	the same check, together with the fundamental theorem of calculus
the flux through the brane $z = \pi/2$ vanishes (the no-flux condition), so that Q is constant	OPEN: not derived for every solution; it fails for exact solutions of Section 18.21, for example the one of Notebook 18c, whose flow through the brane ranges from -0.3454 to 0.3454, and it holds for the stationary members of that family (PROVED above); ASSUMED in the Kohn-Sham model of Chapter 14 (the Z2 mirror) and wherever a constant total charge is used	`Revision/theory/reports/python-scope.json`, check `good_sector_hermiticity_up_to_the_brane_flux`; the detail text of the check `u1_noether_matrix_identity` (the constancy of Q is not established); Notebook 18c; `Revision/kohn_sham/ks-theory.json`, entry `boundaryConditions.brane` (status ASSUMED)

Notebook 05a re-checks the first three rows.

5.7 Example: Notebook 05a checks C, Γ and B

Notebook 05a reads the eight gammas from the record `Revision/algebra/gammas.json` as exact whole numbers and checks, one by one, every statement of Sections 5.2 to 5.6. It reads the two reports of the record and, for every check that repeats a recorded check, prints a second line naming the report file and the check. It tests the squaring rule of Section 5.3 on all 255 products of different gammas, evaluates the quadratic form of C along two paths, computes the characteristic polynomial of B exactly with sympy, counts the eigenvalues of all eleven matrices and draws six teaching figures: heat maps of C and σ, the two values of the quadratic form, heat maps of Γ, its projectors and $\gamma^{(x1)}$, heat maps of the matrices that make B, the table of eigenvalue counts and the table of commutation signs. Its last line is ALL 26 CHECKS PASSED (notebook 05a).

5.8 How to run Notebook 05a

Step 1. What this notebook does and what it needs.

Notebook 05a (The matrices C, Gamma and B built from the author's gammas) is the file `Revision/textbook/notebooks/05a_c_gamma_b.ipynb` of the repository Dirac_claude. It reads the eight real 16 by 16 gamma matrices of the Revision record, checks the Clifford relation, builds the charge matrix C (the product of the four space-like gammas), the chirality Gamma (the product of all eight gammas) and the matrix B = -i C gamma^(x4), checks again with its own code every property that the Revision record states about them (symmetry, squares, commutation signs, eigenvalues and signature; COMPUTED here, partly in exact whole-number arithmetic and partly in floating-point numbers, while the record proves them exactly), and draws six teaching plots: heat maps of the matrices, an indefinite quadratic form, the spectra and a table of commutation signs. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05a_c_gamma_b.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05a_c_gamma_b.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05a_c_gamma_b.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/05a.captions.json`
- `Revision/textbook/figures/05a_1_c_matrix.png`
- `Revision/textbook/figures/05a_2_c_form_signs.png`
- `Revision/textbook/figures/05a_3_chirality.png`
- `Revision/textbook/figures/05a_4_b_matrix.png`
- `Revision/textbook/figures/05a_5_spectra.png`
- `Revision/textbook/figures/05a_6_commutation_signs.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05a exist
ALL 26 CHECKS PASSED (notebook 05a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/05a_c_gamma_b.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05a_c_gamma_b.ipynb
python -m nbconvert --execute --inplace 05a_c_gamma_b.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming `Revision/algebra/gammas.json`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

5.9 Notebook 05a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05a_c_gamma_b.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The author's theory uses eight real $16 \times 16$ matrices, the *gamma matrices*
$\gamma^{(x0)}, \dots, \gamma^{(x7)}$, one for each coordinate direction. From them
the theory builds three further matrices that appear in every formula of the book:

- the **charge matrix** $C = \gamma^{(x0)} \gamma^{(x1)} \gamma^{(x2)} \gamma^{(x3)}$,
  the product of the four space-like gammas (the author calls it sigma16);
- the **chirality** $\Gamma = \gamma^{(x0)} \gamma^{(x1)} \gamma^{(x2)} \cdots
  \gamma^{(x7)}$, the product of all eight gammas;
- the matrix $B = -i\, C \gamma^{(x4)}$, where $i$ is the imaginary unit
  ($i^2 = -1$).

This notebook reads the gammas from the Revision record
`Revision/algebra/gammas.json`, checks the Clifford relation, builds $C$, $\Gamma$
and $B$, and checks every property that the Revision reports
`Revision/algebra/reports/python-algebra.json` and
`Revision/algebra/reports/wolfram-algebra.json` record about them: which of them are
symmetric, what their squares are, with which gammas they commute or anticommute,
their eigenvalues, and the *signature* $(8, 8)$ of $C$ and $B$. Every check that
repeats a recorded check prints the record file and the check name. It draws six
teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 05a (The matrices C, Gamma and B built from the author's gammas) is the file
'Revision/textbook/notebooks/05a_c_gamma_b.ipynb' of the repository Dirac_claude. It
reads the eight real 16 by 16 gamma matrices of the Revision record, checks the Clifford
relation, builds the charge matrix C (the product of the four space-like gammas), the
chirality Gamma (the product of all eight gammas) and the matrix B = -i C gamma^(x4),
checks again with its own code every property that the Revision record states about them
(symmetry, squares, commutation signs, eigenvalues and signature; COMPUTED here, partly
in exact whole-number arithmetic and partly in floating-point numbers, while the record
proves them exactly), and draws six teaching plots: heat maps of the matrices, an
indefinite quadratic form, the spectra and a table of commutation signs. It needs a
computer with Windows 11, macOS or Linux, an internet connection for the installation,
the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv

Then close the terminal and open a NEW one (a terminal opened before the installation
does not know the new programs), and check the version of Python; it must print 3.12 or a
higher number:
```

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
```

```
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 05a_c_gamma_b.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05a_c_gamma_b.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05a_c_gamma_b.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05a.captions.json‘
- ‘Revision/textbook/figures/05a_1_c_matrix.png‘
- ‘Revision/textbook/figures/05a_2_c_form_signs.png‘
- ‘Revision/textbook/figures/05a_3_chirality.png‘
- ‘Revision/textbook/figures/05a_4_b_matrix.png‘
- ‘Revision/textbook/figures/05a_5_spectra.png‘
- ‘Revision/textbook/figures/05a_6_commutation_signs.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05a exist
ALL 26 CHECKS PASSED (notebook 05a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
    python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from
  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/05a_c_gamma_b.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 05a_c_gamma_b.ipynb
      python -m nbconvert --execute --inplace 05a_c_gamma_b.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming ‘Revision/algebra/gammas.json‘: the notebook was opened
  outside the repository, or the repository is incomplete; clone the repository again and
  open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 05a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05a (The matrices C, Gamma and B built from the author’s gammas) is the file
# Revision/textbook/notebooks/05a_c_gamma_b.ipynb of the repository Dirac_claude. It
# reads the eight real 16 by 16 gamma matrices of the Revision record, checks the
# Clifford relation, builds the charge matrix C (the product of the four space-like
```

```
# gammas), the chirality Gamma (the product of all eight gammas) and the matrix B = -i C
# gamma^(x4), checks again with its own code every property that the Revision record
# states about them (symmetry, squares, commutation signs, eigenvalues and signature;
# COMPUTED here, partly in exact whole-number arithmetic and partly in floating-point
# numbers, while the record proves them exactly), and draws six teaching plots: heat maps
# of the matrices, an indefinite quadratic form, the spectra and a table of commutation
# signs. It needs a computer with Windows 11, macOS or Linux, an internet connection for
# the installation, the program Git, and Python 3.12 or newer (the notebooks were built
# with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
```

```
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
```

```
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05a_c_gamma_b.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05a_c_gamma_b.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 05a_c_gamma_b.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
```

```
# - Revision/textbook/figures/05a.captions.json
# - Revision/textbook/figures/05a_1_c_matrix.png
# - Revision/textbook/figures/05a_2_c_form_signs.png
# - Revision/textbook/figures/05a_3_chirality.png
# - Revision/textbook/figures/05a_4_b_matrix.png
# - Revision/textbook/figures/05a_5_spectra.png
# - Revision/textbook/figures/05a_6_commutation_signs.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the six figure files of notebook 05a exist
#     ALL 26 CHECKS PASSED (notebook 05a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05a_c_gamma_b.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05a_c_gamma_b.ipynb
#     python -m nbconvert --execute --inplace 05a_c_gamma_b.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
```

```
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming Revision/algebra/gammas.json: the notebook was opened
#   outside the repository, or the repository is incomplete; clone the repository again
#   and open the notebook from its folder Revision/textbook/notebooks.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Matrix**: a rectangular table of numbers. A $16 \times 16$ matrix has 16 rows and
  16 columns. The entry in row $r$ and column $c$ of the matrix $M$ is written
  $M_{rc}$; rows and columns are numbered 1 to 16 in the text and in the plots.
- **Matrix product**: $(MN)_{rc} = \sum_k M_{rk} N_{kc}$. In Python the sign ‘@‘
  multiplies two matrices. The order matters: $MN$ and $NM$ are in general
  different.
- **Identity matrix** $1$: ones on the diagonal, zeros elsewhere; $1M = M1 = M$.
- **Commute, anticommute**: $M$ and $N$ *commute* when $MN = NM$ and *anticommute*
  when $MN = -NM$.
- **Anticommutator**: $\{M, N\} = MN + NM$.
- **Transpose** $M^T$: the matrix with rows and columns exchanged,
  $(M^T)_{rc} = M_{cr}$. $M$ is **symmetric** when $M^T = M$ and **antisymmetric**
  when $M^T = -M$.
- **Inverse** $M^{-1}$: the matrix with $M M^{-1} = M^{-1} M = 1$. When $MM = 1$,
  the matrix is its own inverse.
- **Complex conjugate**: for a complex number $z = a + ib$ ($a$, $b$ real) it is
  $z^* = a - ib$. For a matrix, $M^*$ conjugates every entry, and the
  **conjugate transpose** is $M^\dagger = (M^*)^T$. A matrix with $M^\dagger = M$
```

```
  is **Hermitian**.
- **Eigenvalue, eigenvector**: a number $\lambda$ and a column $v \neq 0$ with
  $Mv = \lambda v$. The list of all eigenvalues (counted with their multiplicity)
  is the **spectrum** of $M$.
- **Trace** $\mathrm{tr}\, M$: the sum of the diagonal entries; it equals the sum
  of the eigenvalues.
- **Signature** $(p, q)$ of a symmetric or Hermitian matrix: it has $p$ positive
  and $q$ negative eigenvalues. A signature with both $p > 0$ and $q > 0$ is
  *indefinite*: the quadratic form $u^T M u$ (or $u^\dagger M u$) takes both
  signs.
- **Signed permutation matrix**: exactly one nonzero entry, $+1$ or $-1$, in each
  row and in each column.
- **Block**: a $16 \times 16$ matrix cut into four $8 \times 8$ pieces; rows and
  columns 1 to 8 form the first half, 9 to 16 the second half.
  $\mathrm{diag}(X, Y)$ is the matrix with the blocks $X$ (top left) and $Y$
  (bottom right) and zeros elsewhere.
- **Projector**: a matrix with $PP = P$.
- **Heat map**: a picture of a matrix in which every entry is a coloured square; in
  this notebook $-1$ is blue, $0$ light grey and $+1$ red.
- **Record, check**: a Revision record is a file of the repository written by the
  Revision programs; a *check* in it has a name, a verdict (pass or fail) and a
  detail text.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's spacetime has eight coordinates $x0, \dots, x7$: $x1, x2, x3$ are
ordinary 3-space, $x4$ is the time, $x5, x6, x7$ are three extra times (they deflate
exponentially in the author's metric) and $x0$ is a hidden space direction. The
flat metric of the frame is

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

in the order $x0, \dots, x7$: the four directions with $\eta_{aa} = +1$ ($x1, x2,
x3, x0$) are *space-like*, the four with $\eta_{aa} = -1$ ($x4, x5, x6, x7$) are
*time-like*. The gamma matrices obey the **Clifford relation**

$$\{\gamma^a, \gamma^b\} = 2 \eta^{ab}\, 1 ,$$

that is: $\gamma^a \gamma^a = \eta_{aa} 1$ (a space-like gamma squares to $+1$, a
time-like one to $-1$), and two different gammas anticommute.

**The sign rule for moving a gamma.** Let $P$ be a product of $k$ *different*
gammas. Move $\gamma^a$ from the left of $P$ to its right, one factor at a time.
Passing a factor different from $\gamma^a$ costs a sign $-1$ (they anticommute);
passing $\gamma^a$ itself costs nothing. Hence

- if $\gamma^a$ is one of the $k$ factors: $\gamma^a P = (-1)^{k-1} P \gamma^a$;
- if it is not: $\gamma^a P = (-1)^{k} P \gamma^a$.

For $C$ ($k = 4$, factors $x0, x1, x2, x3$): a space-like gamma is a factor and
gives $(-1)^3 = -1$ (anticommutes); a time-like gamma is not a factor and gives
```

```
$(-1)^4 = +1$ (commutes). In one formula: $C\gamma^a = -\eta_{aa}\, \gamma^a C$.

**The sign rule for squaring a product.** Write
$P = \gamma^{a_1} \cdots \gamma^{a_k}$ with different $a_j$. In $PP$, move the
second copy of $\gamma^{a_1}$ to the left until it meets the first copy: it passes
$k - 1$ different factors, giving $(-1)^{k-1}$, and then
$\gamma^{a_1}\gamma^{a_1} = \eta_{a_1 a_1}$. Repeating with $\gamma^{a_2}$
($k - 2$ passes), and so on, gives

$$P P = (-1)^{(k-1) + (k-2) + \dots + 0}\ \eta_{a_1 a_1} \cdots \eta_{a_k a_k}\, 1
    = (-1)^{k(k-1)/2}\ \eta_{a_1 a_1} \cdots \eta_{a_k a_k}\, 1 .$$

For $C$: $(-1)^{6} (+1)^4 = +1$, so $CC = 1$. For $\Gamma$ ($k = 8$): $(-1)^{28}
(+1)^4 (-1)^4 = +1$, so $\Gamma\Gamma = 1$. For $C\gamma^{(x4)}$ ($k = 5$):
$(-1)^{10} (+1)^4 (-1) = -1$, so $BB = (-i)^2 (C\gamma^{(x4)})^2 = (-1)(-1) = 1$.

**Why a matrix with $MM = 1$ and trace 0 has eight eigenvalues $+1$ and eight
$-1$.** If $Mv = \lambda v$, then $v = MMv = \lambda^2 v$, so $\lambda = \pm 1$.
The trace is the sum of the 16 eigenvalues: $n_+ - n_- = 0$ and $n_+ + n_- = 16$
give $n_+ = n_- = 8$. For a time-like gamma, $\gamma\gamma = -1$ gives
$\lambda^2 = -1$, so $\lambda = \pm i$, again eight of each.

The notebook checks each of these statements on the actual matrices.
```

```
## 5. The eight gamma matrices from the Revision record

The next cell reads the record ‘Revision/algebra/gammas.json‘. It holds the gammas in
the order $x0, \dots, x7$ as lists of rows of whole numbers. ‘np.array‘ turns each
list into a numpy matrix of whole numbers (‘int64‘), so every product below is
computed **exactly** (no rounding). The dictionary ‘gamma‘ gives each matrix by the
name of its coordinate: ‘gamma["x4"]‘ is $\gamma^{(x4)}$.
```

In [2]:

```
import numpy as np  # arrays of numbers, matrices and linear algebra

FIXTURE = "Revision/algebra/gammas.json"  # the Revision record of the gammas
fixture = json.loads(repository_file(FIXTURE).read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # the coordinate names "x0", "x1", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # eta_aa: +1 space-like, -1 time-like
# gamma["x0"], ..., gamma["x7"]: the eight 16 x 16 matrices of whole numbers
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the 16 x 16 identity matrix, written 1 in the text
for x in COORDS:
    kind = "space-like" if ETA[x] == 1 else "time-like"
    rows, columns = gamma[x].shape  # the numbers of rows and of columns
    say(f"gamma^({x}): {rows} x {columns}, eta = {ETA[x]:+d} ({kind})")
```

Out [2]:

```
gamma^(x0): 16 x 16, eta = +1 (space-like)
gamma^(x1): 16 x 16, eta = +1 (space-like)
gamma^(x2): 16 x 16, eta = +1 (space-like)
gamma^(x3): 16 x 16, eta = +1 (space-like)
gamma^(x4): 16 x 16, eta = -1 (time-like)
gamma^(x5): 16 x 16, eta = -1 (time-like)
gamma^(x6): 16 x 16, eta = -1 (time-like)
gamma^(x7): 16 x 16, eta = -1 (time-like)
```

Text cell:

```
The next cell reads the two Revision reports whose checks this notebook repeats, and
defines three small helpers: ‘recorded(key, name)‘ is true when the report ‘key‘
("python" or "wolfram") holds the check ‘name‘ with the verdict pass;
‘record_of(key, name)‘ is the text that a check prints after the word
"reproduces"; and ‘check_reproduces(condition, name, record)‘ is the helper ‘check‘
for a check that reproduces a Revision record. It lets ‘check‘ print the PASS line
and the line "reproduces ..." into a text buffer (‘contextlib.redirect_stdout‘) and
then sends both lines with one ‘sys.stdout.write‘: Jupyter delivers printed text in
pieces, and one piece keeps the two lines together, so that the tools that read the
notebook always see them as one check. The first check confirms the order of the
coordinates and the signs of $\eta$.
```

In [3]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

## 7. C defines an indefinite quadratic form

For a real column $u$ of 16 numbers the number $u^T C u = \sum_{r,c} u_r C_{rc}
u_c$ is a *quadratic form*. Because $C$ has eigenvalues of both signs, this form
takes both signs. Take the path $u(t) = \cos t\, e_1 + \sin t\, e_5$, where $e_r$ is
the column with a 1 in row $r$ and zeros elsewhere. Only the entries $C_{1,5} =
C_{5,1}$ meet two nonzero components, so $u^T C u = 2 \cos t \sin t\, C_{1,5} =
C_{1,5} \sin 2t$ (double-angle formula $2\sin t\cos t = \sin 2t$). Along the path
$v(t) = \cos t\, e_9 + \sin t\, e_{13}$ the same steps give $C_{9,13} \sin 2t$. The
next cell reads $C_{1,5} = -1$ and $C_{9,13} = +1$ from the matrix (Python counts
rows from 0, so row 1 is index 0), evaluates both forms on 401 values of $t$ and
checks them against the formulas. It also computes the eigenvalues of $C$
(‘np.linalg.eigvalsh‘ is made for symmetric matrices) and counts the positive and
negative ones.
```

In [11]:

```
t = np.linspace(0.0, np.pi, 401)  # 401 equally spaced values of t from 0 to pi
e = np.eye(16)  # e[r - 1] is the column e_r (a 1 in row r)

## 8. The chirality Gamma and the two halves

The next cell builds $\Gamma = \gamma^{(x0)} \gamma^{(x1)} \cdots \gamma^{(x7)}$ (the
author's product order) and checks four recorded facts:

1. $\Gamma$ equals the recorded matrix and is $\mathrm{diag}(-1_8, 1_8)$;
2. $\Gamma\Gamma = 1$ and $\Gamma$ anticommutes with every $\gamma^a$ (sign rule:
   every gamma is one of the 8 factors, $(-1)^{8-1} = -1$);
3. $\Gamma = C \gamma^{(x4)}\gamma^{(x5)}\gamma^{(x6)}\gamma^{(x7)}$ (the first four
   factors of $\Gamma$ are $C$);
4. $C\Gamma = \Gamma C$ (both are products of an even number of gammas),
   $\Gamma^T = \Gamma$, $\Gamma^T C \Gamma = C$ and
   $\Gamma^T C\gamma^a \Gamma = -C\gamma^a$ for every $a$.

Fact 4 is the matrix input of the pairing theorem T1 of the Revision record: the
map $\Psi \to \Gamma\Psi$ keeps the bilinear $\Psi^\dagger C \Psi$ (because
$(\Gamma\Psi)^\dagger C(\Gamma\Psi) = \Psi^\dagger\Gamma^T C\Gamma\Psi$, $\Gamma$
being real) and reverses the sign of every $\Psi^\dagger C\gamma^a E\Psi$ in which
$E$ is a product of an even number of gammas ($\Gamma$ commutes with such an $E$).
```

```
Because $\Gamma\Gamma = 1$, the matrices $P_- = \tfrac12(1 - \Gamma)$ and
$P_+ = \tfrac12(1 + \Gamma)$ are projectors: $P_-P_- = \tfrac14(1 - 2\Gamma +
\Gamma\Gamma) = \tfrac14(2 - 2\Gamma) = P_-$, and in the same way $P_+P_+ = P_+$ and
$P_-P_+ = \tfrac14(1 - \Gamma\Gamma) = 0$. With $\Gamma = \mathrm{diag}(-1_8, 1_8)$,
$P_- = \mathrm{diag}(1_8, 0)$ keeps the first half of a column (components 1 to 8,
chirality $-1$) and $P_+ = \mathrm{diag}(0, 1_8)$ the second half (9 to 16,
chirality $+1$). Since $\gamma^a\Gamma = -\Gamma\gamma^a$, we get $\gamma^a P_- =
\tfrac12(\gamma^a + \Gamma\gamma^a) = P_+\gamma^a$: every gamma carries the first
half into the second and back, so every gamma has zero diagonal blocks. The next
cell checks all of this (‘//‘ divides whole numbers exactly; the entries of
$1 \pm \Gamma$ are 0 or 2).

## 9. The matrix B

The next cell builds $B = -i\, C\gamma^{(x4)}$ (in Python the imaginary unit is
written ‘1j‘) and checks it against the record, which stores the real and the
imaginary part separately. Then it checks the recorded properties: $B$ is purely
imaginary, Hermitian ($B^\dagger = B$), $BB = 1$ and $\mathrm{tr}\, B = 0$. Why
Hermitian: $C\gamma^{(x4)}$ is real and antisymmetric (section 6), so
$B^\dagger = (+i)(C\gamma^{(x4)})^T = (+i)(-C\gamma^{(x4)}) = B$. The entries of $B$
are $0$, $i$ or $-i$, so every product is again exact.
```

In [16]:

```
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4); 1j is the imaginary unit
B_record = (np.array(fixture["B"]["re"], dtype=np.int64)

## 13. What this notebook showed

- The eight gammas of the Revision record are real signed permutation matrices
  that obey the Clifford relation $\{\gamma^a, \gamma^b\} = 2\eta^{ab}1$; the
  space-like ones ($x0, x1, x2, x3$) are symmetric, the time-like ones ($x4, x5,
  x6, x7$) antisymmetric.
- $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)} =
  \mathrm{diag}(-\sigma, \sigma)$ is real and symmetric, $CC = 1$, it anticommutes
  with the space-like and commutes with the time-like gammas, every $C\gamma^a$ is
  antisymmetric and $C\gamma^a C^{-1} = -(\gamma^a)^T$. Its quadratic form has
  signature $(8, 8)$: it takes both signs.
- $\Gamma = \gamma^{(x0)}\gamma^{(x1)}\cdots\gamma^{(x7)} = \mathrm{diag}(-1_8,
  1_8)$ squares to 1, anticommutes with every gamma, commutes with $C$ and
  satisfies $\Gamma^T C\Gamma = C$ and $\Gamma^T C\gamma^a\Gamma = -C\gamma^a$. Its
  projectors split the 16 components into two halves of 8, and every gamma
  exchanges the halves.
- $B = -iC\gamma^{(x4)}$ is purely imaginary and Hermitian with $BB = 1$, its
  characteristic polynomial is $(\lambda - 1)^8(\lambda + 1)^8$ (signature
  $(8, 8)$), and it anticommutes exactly with the gammas of the three extra times.
- The squaring rule $(-1)^{k(k-1)/2}\prod\eta$ holds for all 255 products of
  different gammas.
- Every check printed with a line "reproduces ..." repeats a check of the Revision
  reports ‘Revision/algebra/reports/python-algebra.json‘ and
  ‘wolfram-algebra.json‘, whose verdicts the notebook read and confirmed. The
  squaring rule for all 255 products, the quadratic form along the two paths, the
  commutation signs of $C$ with each gamma and the eigenvalue counts are this
  notebook’s own computations.
```

5.10 Line-by-line walk-through of Notebook 05a

The notebook has 23 code cells, In [1] to In [23]. This section explains every line of every one of them. The words used are those of the notebook's section 3 (matrix, product, transpose, eigenvalue, signature, heat map and so on), which Sections 5.2 to 5.6 defined. When a cell gives a long caption to `save_figure`, the quotation replaces the caption, or the rest of it, by a line `...`); the full caption is printed under the figure in the complete text of the notebook (Section 5.9). The docstrings of the functions (explained under In [1] below) are left out of all quotations.

In [1], the set-up cell. It is the same in every notebook of the book; only the line that sets `NOTEBOOK_ID` differs. Its first part repeats the complete run instructions of Section 5.8 as comment lines: every line that starts with `#` is a **comment**, which Python skips. The code starts after the line THE SET-UP between two lines of `=` signs. (The function definitions in the cell also carry **docstrings**, texts in triple quotes below the `def` line that say what the function does; they are left out of the quotations here.)

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json`, `os`, `textwrap` and `pathlib` come with Python; `from pathlib import Path` takes the single name `Path` out of `pathlib`. A `Path` is the address of a file or folder, written the same way on every operating system. The plotting package matplotlib is loaded together with its drawing functions under the short name `plt`, and `Image` and `display` come from IPython, the part of Jupyter that runs Python code; together they show a saved picture below a cell.

```
NOTEBOOK_ID = "05a"  # this notebook: chapter 05, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"05a"`. The figure files and the last line of the notebook use it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` lists

the parent folder, its parent and so on; `[here, *here.parents]` is the list that starts with `here` and continues with all of them. The `for` loop takes the folders one after the other; `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If there is none, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The comment lines say in short what the two code lines do. The first code line calls the function and names its result `REPO`; it is never printed, because it differs from computer to computer while the printed output of a notebook must not. The second line chooses the folder below which files are written. `os.environ` holds the **environment variables** (named texts that a program receives from the computer); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and the repository folder otherwise. When you run the notebook the variable is not set; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` is the full path of a repository file, for reading a Revision record. `output_file("Revision/...")` is the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates its folder (and any missing folder above it) and does nothing if it exists.

```
def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of the book; `textwrap.fill` breaks the text at blanks, and every line after the first starts with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings of matplotlib, so that the figures are the same on every computer. `plt.rcParams.update({...})` then sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid behind the curves. The braces make a **dictionary**: pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: each name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/05a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary `{}` and a line end into the captions file, which `save_figure` then fills; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, and a cell run twice keeps its number. The file name joins the notebook id, the number and the name, for example `05a_1_c_matrix.png`. `fig.savefig` writes the picture as a PNG file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time. The caption is stored and the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys). `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
```

```
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list**, an ordered collection written with square brackets. `check` is the function behind every check of the book. `condition` is either `True` or `False`; if it is false, `raise AssertionError(...)` stops the notebook with an error that names the check (Python's own statement `assert` is not used, because Python started with the option `-O` skips it). If it is true, the name is appended to `PASSED` and the line PASS name is printed; when the optional third argument names a Revision record, a second line says which record and check the result reproduces.

```
def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT, followed by the unit when one is given. `all_checks_passed` prints the last line of the notebook with the number of checks that passed (`len` is the length of a list). The last statement prints the single output line of In [1].

In [2], the gammas from the record.

```
import numpy as np  # arrays of numbers, matrices and linear algebra

FIXTURE = "Revision/algebra/gammas.json"  # the Revision record of the gammas
fixture = json.loads(repository_file(FIXTURE).read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # the coordinate names "x0", "x1", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # eta_aa: +1 space-like, -1 time-like
```

numpy is loaded under the short name `np`. `read_text` reads the record file as text and `json.loads` turns the text into Python objects: `fixture` is a dictionary whose keys are the names stored in the record. `fixture["coordinates"]` is the list `["x0", ..., "x7"]`. `zip` pairs each coordinate name with its entry of the list `fixture["eta"]`, and `dict` makes a dictionary of the pairs, so `ETA["x4"]` is -1.

```
# gamma["x0"], ..., gamma["x7"]: the eight 16 x 16 matrices of whole numbers
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the 16 x 16 identity matrix, written 1 in the text
```

The comment line names what the next line builds. A **dictionary comprehension** `{x: ... for x, m in ...}` builds a dictionary in one line: for each pair of a name `x` and a stored matrix `m` (a list of 16 rows of 16 whole numbers) it stores `np.array(m, dtype=np.int64)`, the same matrix as a numpy array of 64-bit whole numbers. With whole numbers every product below is exact: nothing is rounded. `np.eye(16)` is the identity matrix.

```
for x in COORDS:
    kind = "space-like" if ETA[x] == 1 else "time-like"
    rows, columns = gamma[x].shape  # the numbers of rows and of columns
    say(f"gamma^({x}): {rows} x {columns}, eta = {ETA[x]:+d} ({kind})")
```

For each direction the loop chooses the word space-like or time-like (`a if condition else b` is `a` when the condition holds and `b` otherwise), reads the shape of the matrix (16 rows and 16 columns) and prints one line; `{ETA[x]:+d}` writes the whole number with its sign. The eight printed lines show eight 16×16 matrices, four with $\eta = +1$ and four with $\eta = -1$.

In [3], the recorded checks.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

REPORT_FILES = {"python": "Revision/algebra/reports/python-algebra.json",
                "wolfram": "Revision/algebra/reports/wolfram-algebra.json"}
VERDICTS = {}  # (report key, check name) -> (verdict in lower case, detail text)
for key, path in REPORT_FILES.items():
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in report_data["checks"]:
        VERDICTS[(key, entry["name"])] = (entry["verdict"].lower(), entry["detail"])
```

Three more modules of Python are loaded. `REPORT_FILES` names the two reports of the record. The loop reads each report; `report_data["checks"]` is its list of checks, each a dictionary with the keys `name`, `verdict` and `detail`. Every check is stored in `VERDICTS` under the pair (report key, check name); `.lower()` writes the verdict in small letters, because one report writes PASS and the other pass.

```
def recorded(key, name):
    return VERDICTS[(key, name)][0] == "pass"

def record_of(key, name):
    return f"{REPORT_FILES[key]}, check {name}"
```

`recorded("python", "clifford_relation")` is true when the Python report holds that check with the verdict pass (`[0]` takes the first element of the stored pair). `record_of` builds the text that a reproducing check prints after the word reproduces.

```
def check_reproduces(condition, name, record):
    collected = io.StringIO()
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together
```

This is `check` for a check that reproduces a record. Inside the `with` block everything printed goes into the text buffer `collected` instead of the screen; `check` prints its PASS line and its reproduces

line there (or stops the notebook if the condition is false). Then `sys.stdout.write` sends both lines at once. Jupyter delivers printed text in pieces, and one piece keeps the two lines together for the tools that read the notebook.

```
say(f"{len(VERDICTS)} recorded checks were read from the two reports.")
check_reproduces(COORDS == ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
                 and fixture["eta"] == [1, 1, 1, 1, -1, -1, -1, -1]
                 and recorded("wolfram", "eta_in_author_order"),
                 "the coordinates are x0..x7 and eta = diag(+1,+1,+1,+1,-1,-1,-1,-1)",
                 record=record_of("wolfram", "eta_in_author_order"))
```

The first line prints the number of recorded checks read: 80, the 35 of the Python report and the 45 of the Wolfram report. The check compares the list of coordinate names and the list of the signs of η with the expected lists (`==` compares two lists element by element) and requires that the Wolfram report recorded the same fact; `and` is true only when all its parts are true. It prints PASS and the record it reproduces.

In [4], the Clifford relation.

```
def anticommutator(m, n):
    return m @ n + n @ m

failures = []  # the pairs (x, y) for which the relation fails
for x in COORDS:
    for y in COORDS:
        # the right side: 2 eta_xx 1 when x = y, the zero matrix otherwise
        expected = 2 * ETA[x] * I16 if x == y else np.zeros_like(I16)
        if not np.array_equal(anticommutator(gamma[x], gamma[y]), expected):
            failures.append((x, y))
```

In Python the sign `@` multiplies two matrices, so `anticommutator(m, n)` is $mn + nm$. Two loops run through all $8 \times 8 = 64$ ordered pairs of directions. For each pair the right side of the Clifford relation is $2\eta_{xx}1$ when the two directions are equal and the zero matrix (`np.zeros_like(I16)`, zeros of the same shape) otherwise. `np.array_equal` is true only when all 256 entries agree; a pair for which they do not is appended to `failures`.

```
say(f"pairs tested: {len(COORDS) ** 2}; pairs that fail: {len(failures)}")
check_reproduces(failures == [] and recorded("python", "clifford_relation"),
                 "{gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs",
                 record=record_of("python", "clifford_relation"))
```

`**` is the power in Python, so `len(COORDS) ** 2` is 64. The printed line reports 64 pairs tested and 0 failures, and the check requires the list of failures to be empty.

In [5], signed permutations and the symmetry pattern.

```
values = sorted({int(v) for x in COORDS for v in gamma[x].flat})  # every entry once
one_per_row = all((gamma[x] != 0).sum(axis=1).tolist() == [1] * 16 for x in COORDS)
one_per_column = all((gamma[x] != 0).sum(axis=0).tolist() == [1] * 16 for x in COORDS)
say(f"the entries of the gammas are {values}")
```

`gamma[x].flat` runs through the 256 entries of a matrix. The braces make a **set**, which keeps every value only once; `sorted` turns it into an ordered list, here `[-1, 0, 1]`. `gamma[x] != 0` is a table of true and false values (true where the entry is not zero); `.sum(axis=1)` counts the true values in each row and `.sum(axis=0)` in each column; `.tolist()` turns the result into a list, and `[1] * 16` is the list of sixteen ones. `all(...)` is true when the condition holds for every direction.

```
check_reproduces(values == [-1, 0, 1] and one_per_row and one_per_column
                 and recorded("python", "reality_signed_permutations"),
                 "every gamma is real and a signed permutation matrix",
                 record=record_of("python", "reality_signed_permutations"))
symmetric = [x for x in COORDS if np.array_equal(gamma[x].T, gamma[x])]
antisymmetric = [x for x in COORDS if np.array_equal(gamma[x].T, -gamma[x])]
say("symmetric gammas: " + ", ".join(symmetric))
say("antisymmetric gammas: " + ", ".join(antisymmetric))
check_reproduces(symmetric == ["x0", "x1", "x2", "x3"]
                 and antisymmetric == ["x4", "x5", "x6", "x7"]
                 and recorded("python", "symmetry_pattern"),
                 "(gamma^a)^T = eta_aa gamma^a: space-like symmetric, time-like "
                 "antisymmetric",
                 record=record_of("python", "symmetry_pattern"))
```

The first check combines the three facts. Then two **list comprehensions** collect the directions whose matrix equals its transpose (`.T` is the transpose) and those whose matrix equals minus its transpose; `", ".join(...)` writes a list of names separated by commas. The printed lines are `x0, x1, x2, x3` and `x4, x5, x6, x7`, and the second check requires exactly these lists: the space-like gammas are symmetric and the time-like ones antisymmetric.

In [6], three helpers.

```
from matplotlib.colors import LinearSegmentedColormap

# Colours of the heat maps: -1 blue, 0 light grey, +1 red (a diverging colour scale).
SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
```

A **colour map** assigns a colour to every number of a range. `from_list` makes one that runs smoothly through the three listed colours (each written as a hexadecimal code of its red, green and blue parts): blue for the lowest value, light grey in the middle, red for the highest.

```
def heat_map(ax, matrix, title, halves=True, row_label=True):
    size = matrix.shape[0]
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ticks = [0, 3, 7, 11, 15] if size == 16 else [0, 3, 7]  # counted from 0
    ax.set_xticks(ticks, [str(t + 1) for t in ticks])  # labels counted from 1
    ax.set_yticks(ticks, [str(t + 1) for t in ticks])
    ax.set_xlabel("column")
    if row_label:
        ax.set_ylabel("row")
    ax.grid(False)  # no grid lines across the coloured squares
    if halves and size == 16:
```

```
        ax.axhline(7.5, color="black", linewidth=0.8)  # between rows 8 and 9
        ax.axvline(7.5, color="black", linewidth=0.8)  # between columns 8 and 9
    return image
```

`heat_map` draws a matrix on the **axes** `ax` (one picture area of a figure). `ax.imshow` draws one coloured square per entry with the colour map `SIGNS`, so that -1 is blue, 0 grey and $+1$ red (`vmin` and `vmax` fix the range). Python counts rows and columns from 0, the book from 1: the tick marks stand at the positions 0, 3, 7, 11, 15 and are labelled 1, 4, 8, 12, 16 (for an 8×8 matrix only 1, 4, 8). The optional argument `row_label=False` leaves out the word row on the second and later pictures of a row of pictures. For a 16×16 matrix two thin black lines at the position 7.5 (between the eighth and the ninth row and column) show the two halves. The function returns the drawn image, which a colour bar needs.

```
def commutation_sign(m, n):
    if np.array_equal(m @ n, n @ m):
        return 1
    if np.array_equal(m @ n, -(n @ m)):
        return -1
    return 0

def product(directions):
    result = I16
    for d in directions:
        result = result @ gamma[d]
    return result

say("helpers heat_map, commutation_sign and product are defined")
```

`commutation_sign(m, n)` returns $+1$ when $mn = nm$, -1 when $mn = -nm$ and 0 when neither holds. `product(["x0", "x1"])` multiplies the gammas of the listed directions in the order of the list, starting from the identity. The cell prints one line.

In [7], the charge matrix.

```
C = product(["x0", "x1", "x2", "x3"])  # the four space-like gammas
C_record = np.array(fixture["C"], dtype=np.int64)  # the C stored in the record
check_reproduces(np.array_equal(C, C_record) and recorded("wolfram", "C_definition"),
                 "C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3) equals the recorded C",
                 record=record_of("wolfram", "C_definition"))
```

$C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$ is computed and compared with the matrix C that the record stores.

```
I4, Z4 = np.eye(4, dtype=np.int64), np.zeros((4, 4), dtype=np.int64)
I8, Z8 = np.eye(8, dtype=np.int64), np.zeros((8, 8), dtype=np.int64)
sigma = np.block([[Z4, I4], [I4, Z4]])  # the author's 8 x 8 matrix sigma
check_reproduces(np.array_equal(C, np.block([[-sigma, Z8], [Z8, sigma]]))
                 and recorded("python", "C_equals_notebook_sigma16"),
                 "C = diag(-sigma, sigma), called sigma16 by the author",
```

```
                record=record_of("python", "C_equals_notebook_sigma16"))
check_reproduces(np.array_equal(C.T, C) and np.array_equal(C @ C, I16)
                and recorded("python", "C_real_symmetric_involution"),
                "C is real and symmetric, and C C = 1 (so C is its own inverse)",
                record=record_of("python", "C_real_symmetric_involution"))
```

The first two lines make identity and zero matrices of sizes 4 and 8 (a line `A, B = p, q` names two values at once). `np.block` assembles a matrix from a list of rows of blocks: `[[Z4, I4], [I4, Z4]]` is the author's σ, and `[[-sigma, Z8], [Z8, sigma]]` is $\mathrm{diag}(-\sigma, \sigma)$. The two checks confirm (C7), then (C2) and (C3) of Section 5.4.

In [8], the picture of C.

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.4), width_ratios=[2, 1])
heat_map(axes[0], C, r"$C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$")
image = heat_map(axes[1], sigma, r"$\sigma$ (8 x 8)", halves=False,
                row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.75, label="matrix entry")
save_figure(fig, "c_matrix",
            "Heat maps of the charge matrix $C$ (left, 16 by 16) and of the "
            ...)
```

`plt.subplots(1, 2, ...)` makes a figure with one row of two picture areas; `width_ratios=[2, 1]` makes the first twice as wide as the second. A string that starts with `r` is a **raw string**: its backslashes are kept as they are, which the mathematical titles (typeset by matplotlib between dollar signs) need. The first heat map shows C, the second σ without the half lines. `fig.colorbar` adds a bar that shows which colour means which value, with ticks at -1, 0, $+1$, shrunk to three quarters of the height. `save_figure` saves the figure as `05a_1_c_matrix.png` with its caption (the full caption is printed in the notebook text above; Python joins strings written next to each other into one). In the figure, look at the top-left block: blue squares in the pattern of σ; the bottom-right block: red squares in the same pattern; the picture is mirror-symmetric about its diagonal, because $C^T = C$.

In [9], how C moves past the gammas.

```
signs_C = {x: commutation_sign(C, gamma[x]) for x in COORDS}  # +1 or -1 for each x
say("C gamma^(x) = s gamma^(x) C with s = "
    + ", ".join(f"{x}: {signs_C[x]:+d}" for x in COORDS))
check(all(signs_C[x] == -ETA[x] for x in COORDS),
      "C gamma^a = -eta_aa gamma^a C (anticommutes with space-like, commutes with "
      "time-like gammas)")
```

`signs_C` stores, for each direction, the sign s in $C\gamma^a = s\,\gamma^a C$. The printed line lists them: -1 for $x0$, $x1$, $x2$, $x3$ and $+1$ for $x4$ to $x7$. The check is (C1): $s = -\eta_{aa}$ for every direction. It is this notebook's own check (no record holds it in this form), so it prints no reproduces line.

```
check_reproduces(all(np.array_equal((C @ gamma[x]).T, -(C @ gamma[x])) for x in COORDS)
                and recorded("python", "C_gamma_antisymmetric"),
                "C gamma^a is antisymmetric for every a",
```

```
                record=record_of("python", "C_gamma_antisymmetric"))
check_reproduces(all(np.array_equal(C @ gamma[x] @ C, -gamma[x].T) for x in COORDS)
                and recorded("python", "C_conjugation"),
                "C gamma^a C^-1 = -(gamma^a)^T for every a",
                record=record_of("python", "C_conjugation"))
```

The two checks are (C4) and (C5). The second writes $C\gamma^a C$ for $C\gamma^a C^{-1}$, because $C^{-1} = C$.

In [10], the squaring rule on all 255 products.

```
import itertools  # lists all subsets of a given size

def square_sign(directions):
    k = len(directions)
    s = (-1) ** (k * (k - 1) // 2)  # // is division of whole numbers
    for d in directions:
        s *= ETA[d]
    return s
```

`square_sign` computes the sign that Rule 2 of Section 5.3 predicts for the square of the product of the listed directions: $(-1)^{k(k-1)/2}$ times the product of the η_{dd}. `//` divides whole numbers without a remainder ($k(k-1)$ is always even), and `s *= ETA[d]` multiplies `s` by η_{dd}.

```
agree = 0  # how many subsets obey the rule
for k in range(1, 9):
    for subset in itertools.combinations(COORDS, k):
        p = product(subset)
        if np.array_equal(p @ p, square_sign(subset) * I16):
            agree += 1
say(f"subsets tested: 255; subsets that obey the squaring rule: {agree}")
```

`range(1, 9)` runs through $k = 1, \ldots, 8$. `itertools.combinations(COORDS, k)` lists every subset of k directions, each in the order $x0, \ldots, x7$; there are $\binom{8}{k}$ of them, $2^8 - 1 = 255$ in all. For each subset the cell multiplies the gammas, squares the product and compares it with the predicted sign times the identity; `agree += 1` adds one to the counter. The printed line reports 255 of 255.

```
for label, dirs in [("C", ["x0", "x1", "x2", "x3"]),
                    ("Gamma", ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]),
                    ("C gamma^(x4)", ["x0", "x1", "x2", "x3", "x4"])]:
    say(f"({label})^2 = {square_sign(dirs):+d} times 1 (k = {len(dirs)})")
check(agree == 255, "the squaring rule holds for all 255 products of different gammas")
```

The loop prints the predicted squares of the three products used in this chapter: $C^2 = +1$, $\Gamma^2 = +1$ and $(C\gamma^{(x4)})^2 = -1$, the facts behind (C3), (X1) and (B3). The check requires all 255 subsets to agree.

In [11], the quadratic form of C.

```
t = np.linspace(0.0, np.pi, 401)  # 401 equally spaced values of t from 0 to pi
e = np.eye(16)  # e[r - 1] is the column e_r (a 1 in row r)
u = np.outer(np.cos(t), e[0]) + np.outer(np.sin(t), e[4])  # u(t), one per row
v = np.outer(np.cos(t), e[8]) + np.outer(np.sin(t), e[12])  # v(t), one per row
```

`np.linspace(0.0, np.pi, 401)` is an array of 401 numbers from 0 to π with equal steps. `e[0]` is the first row of the identity, the column e_1 written as a row; Python counts from 0, so e_5 is `e[4]`. `np.outer(a, b)` is the table whose row j is the number `a[j]` times the row `b`; so `u` has 401 rows, row j being $\cos t_j\, e_1 + \sin t_j\, e_5$, and `v` holds $\cos t\, e_9 + \sin t\, e_{13}$ in the same way.

```
form_u = np.einsum("tr,rc,tc->t", u, C, u)  # u^T C u for every t at once
form_v = np.einsum("tr,rc,tc->t", v, C, v)  # v^T C v for every t at once
say(f"C_(1,5) = {C[0, 4]:+d} and C_(9,13) = {C[8, 12]:+d}")
check(C[0, 4] == -1 and C[8, 12] == 1
      and np.max(np.abs(form_u + np.sin(2 * t))) < 1e-14
      and np.max(np.abs(form_v - np.sin(2 * t))) < 1e-14,
      "u^T C u = -sin 2t and v^T C v = +sin 2t along the two paths")
```

`np.einsum` evaluates a sum over repeated letters: `"tr,rc,tc->t"` means $\sum_{r,c} u_{tr} C_{rc} u_{tc}$ for every t, that is $u^T C u$ at all 401 times at once. The printed line shows $C_{1,5} = -1$ and $C_{9,13} = +1$ (entries `[0, 4]` and `[8, 12]`). The check compares the computed forms with $-\sin 2t$ and $+\sin 2t$: the largest difference (`np.max(np.abs(...))`) must be below 10^{-14}, because the numbers are now floating-point numbers, which keep about 16 significant digits.

```
eigenvalues_C = np.linalg.eigvalsh(C.astype(float))  # 16 real eigenvalues, sorted
n_plus = int(np.sum(np.abs(eigenvalues_C - 1.0) < 1e-9))  # how many are +1
n_minus = int(np.sum(np.abs(eigenvalues_C + 1.0) < 1e-9))  # how many are -1
say(f"trace of C = {int(np.trace(C))}; eigenvalues +1: {n_plus}, -1: {n_minus}")
check(np.trace(C) == 0 and n_plus == 8 and n_minus == 8,
      "C has eight eigenvalues +1 and eight -1: signature (8, 8)")
```

`np.linalg.eigvalsh` computes the eigenvalues of a symmetric matrix (`.astype(float)` turns the whole numbers into floating-point numbers first). `np.abs(eigenvalues_C - 1.0) < 1e-9` is true for every eigenvalue within 10^{-9} of $+1$, and `np.sum` counts the true values. The printed line shows trace 0, eight $+1$ and eight -1: (C6) of Section 5.4.

In [12], the picture of the two forms.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
ax.plot(t, form_u, color="#2a78d6", linewidth=2,
        label=r"$u^T C u$ with $u = \cos t\, e_1 + \sin t\, e_5$")
ax.plot(t, form_v, color="#eb6834", linewidth=2, linestyle="--",
        label=r"$v^T C v$ with $v = \cos t\, e_9 + \sin t\, e_{13}$")
ax.plot(t, np.einsum("tr,tr->t", u, u), color="#1baf7a", linewidth=2,
        linestyle=":", label=r"$u^T u$ (ordinary squared length)")
ax.axhline(0.0, color="black", linewidth=0.6)
```

`ax.plot(xs, ys, ...)` draws a curve through the points; `color` gives its colour, `linewidth` its thickness, `linestyle` makes it dashed or dotted, and `label` is its name in the legend. The third

curve is $u^T u$ (`"tr,tr->t"` sums $u_{tr} u_{tr}$ over r), which is 1 everywhere. `ax.axhline(0.0)` draws the horizontal line at height 0.

```
ax.set_xticks([0, np.pi / 4, np.pi / 2, 3 * np.pi / 4, np.pi],
              ["0", r"$\pi/4$", r"$\pi/2$", r"$3\pi/4$", r"$\pi$"])
ax.set_xlabel("$t$ (radians)")
ax.set_ylabel("value of the quadratic form")
ax.set_title("The form of $C$ takes both signs; the ordinary length does not")
# the legend goes below the picture, where it hides no curve
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.17), ncol=1)
save_figure(fig, "c_form_signs",
            ...)
```

The tick marks of the horizontal axis are placed at multiples of $\pi/4$ and labelled in radians; the axes and the picture get their labels and title. `ax.legend` draws the box that names the curves; `bbox_to_anchor=(0.5, -0.17)` puts its top centre below the picture, where it hides no curve. The figure, `05a_2_c_form_signs.png`, shows the solid curve $-\sin 2t$ going down to -1, the dashed curve $+\sin 2t$ going up to $+1$, and the dotted line at 1: the form of C takes both signs on unit columns, the ordinary length does not.

In [13], the chirality.

```
Gamma = product(["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"])  # all eight
check_reproduces(np.array_equal(Gamma, np.array(fixture["Gamma"], dtype=np.int64))
                 and np.array_equal(Gamma, np.block([[-I8, Z8], [Z8, I8]]))
                 and recorded("python", "chirality_diag"),
                 "Gamma = gamma^(x0) gamma^(x1) ... gamma^(x7) = diag(-1_8, 1_8), as "
                 "recorded",
                 record=record_of("python", "chirality_diag"))
```

Γ is the product of all eight gammas in the author's order. The check compares it with the recorded matrix and with $\mathrm{diag}(-1_8, 1_8)$: (X9) of Section 5.5.

```
check_reproduces(np.array_equal(Gamma @ Gamma, I16)
                 and all(commutation_sign(Gamma, gamma[x]) == -1 for x in COORDS)
                 and recorded("python", "chirality_anticommutes"),
                 "Gamma Gamma = 1 and Gamma anticommutes with every gamma^a",
                 record=record_of("python", "chirality_anticommutes"))
check_reproduces(np.array_equal(Gamma, C @ product(["x4", "x5", "x6", "x7"]))
                 and recorded("python", "chirality_eq_C_times_time_gammas"),
                 "Gamma = C gamma^(x4) gamma^(x5) gamma^(x6) gamma^(x7)",
                 record=record_of("python", "chirality_eq_C_times_time_gammas"))
```

These are (X1) with (X2), and (X4).

```
check_reproduces(commutation_sign(C, Gamma) == 1 and np.array_equal(Gamma.T, Gamma)
                 and np.array_equal(Gamma.T @ C @ Gamma, C)
                 and all(np.array_equal(Gamma.T @ C @ gamma[x] @ Gamma, -(C @ gamma[x]))
                         for x in COORDS)
```

```
                and recorded("python", "chirality_C_relation"),
                "C Gamma = Gamma C, Gamma^T C Gamma = C, Gamma^T C gamma^a Gamma = -C "
                "gamma^a",
                record=record_of("python", "chirality_C_relation"))
```

This check combines (X5), (X6), (X7) and (X8), the matrix input of the pairing theorem T1.

In [14], the projectors.

```
P_minus = (I16 - Gamma) // 2  # the projector onto components 1 to 8
P_plus = (I16 + Gamma) // 2  # the projector onto components 9 to 16
check(np.array_equal(P_minus, np.block([[I8, Z8], [Z8, Z8]]))
      and np.array_equal(P_plus, np.block([[Z8, Z8], [Z8, I8]]))
      and np.array_equal(P_minus @ P_minus, P_minus)
      and np.array_equal(P_plus @ P_plus, P_plus)
      and not np.any(P_minus @ P_plus) and np.array_equal(P_minus + P_plus, I16)
      and np.trace(P_minus) == 8 and np.trace(P_plus) == 8,
      "P_- = diag(1_8, 0) and P_+ = diag(0, 1_8) are complementary projectors of rank 8")
```

The entries of $1 \pm \Gamma$ are 0 and 2, so the division by 2 with `//` is exact and keeps whole numbers. The check confirms the shapes $\mathrm{diag}(1_8, 0)$ and $\mathrm{diag}(0, 1_8)$, the projector rules $P_- P_- = P_-$, $P_+ P_+ = P_+$, $P_- P_+ = 0$ (`np.any` is true when some entry is not zero, so `not np.any(...)` means the matrix is zero) and $P_- + P_+ = 1$, and that each keeps 8 components (trace 8).

```
check_reproduces(all(np.array_equal(gamma[x] @ P_minus, P_plus @ gamma[x])
                     for x in COORDS)
                and all(not np.any(gamma[x][:8, :8]) and not np.any(gamma[x][8:, 8:])
                        for x in COORDS)
                and recorded("python", "reflections_exchange_halves")
                and recorded("wolfram", "Spin_Pin_reflection_swaps_halves"),
                "gamma^a P_- = P_+ gamma^a: every gamma exchanges the two halves",
                record=record_of("python", "reflections_exchange_halves"))
```

The check is $\gamma^a P_- = P_+ \gamma^a$ for every direction, and that the two diagonal blocks of every gamma are zero. `gamma[x][:8, :8]` is the top-left block: the **slice** `:8` takes the rows (or columns) 0 to 7 in Python's counting, the book's 1 to 8; `8:` takes the rest.

In [15], the picture of the chirality.

```
fig, axes = plt.subplots(1, 4, figsize=(13.0, 3.9))
heat_map(axes[0], Gamma, r"$\Gamma$")
heat_map(axes[1], P_minus, r"$P_- = (1 - \Gamma)/2$", row_label=False)
heat_map(axes[2], P_plus, r"$P_+ = (1 + \Gamma)/2$", row_label=False)
image = heat_map(axes[3], gamma["x1"], r"$\gamma^{(x1)}$ for comparison",
                 row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "chirality",
            ...)
```

Four heat maps in one row and a colour bar, saved as `05a_3_chirality.png`. In the figure, Γ is blue on the first eight diagonal places and red on the last eight; P_- and P_+ are red on the diagonal of one half; $\gamma^{(x1)}$ has its coloured squares only in the two off-diagonal blocks.

In [16], the matrix B.

```
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4); 1j is the imaginary unit
B_record = (np.array(fixture["B"]["re"], dtype=np.int64)
            + 1j * np.array(fixture["B"]["im"], dtype=np.int64))
check_reproduces(np.array_equal(B, B_record) and recorded("wolfram", "B_definition"),
                 "B = -i C gamma^(x4) equals the recorded B",
                 record=record_of("wolfram", "B_definition"))
```

Python writes the imaginary unit as `1j`. The record stores the real and the imaginary part of B separately (`fixture["B"]["re"]` and `fixture["B"]["im"]`), and the cell assembles them into one complex matrix before comparing. The entries of B are 0, i and $-i$, which the computer stores exactly.

```
check_reproduces(not np.any(B.real) and np.array_equal(B.conj().T, B)
                 and np.array_equal(B @ B, I16) and np.trace(B) == 0
                 and recorded("python", "B_hermitian_involution_signature")
                 and recorded("wolfram", "B_Hermitian")
                 and recorded("wolfram", "B_squared_identity"),
                 "B is purely imaginary and Hermitian, B B = 1 and tr B = 0",
                 record=record_of("python", "B_hermitian_involution_signature"))
```

`B.real` is the real part (it must be zero everywhere), and `B.conj().T` the conjugate transpose $B^\dagger$. The check combines (B1) to (B4).

In [17], the characteristic polynomial of B.

```
import sympy as sp  # exact algebra with symbols

lam = sp.Symbol("lam")  # the variable lambda of the polynomial
B_exact = sp.I * sp.Matrix((-(C @ gamma["x4"])).tolist())  # B with exact sympy numbers
polynomial = sp.factor(B_exact.charpoly(lam).as_expr())  # det(lam 1 - B), factored
say(f"characteristic polynomial of B: {polynomial}")
```

sympy computes with symbols and exact numbers. `sp.Symbol("lam")` is the letter λ. Since $B = -iC\gamma^{(x4)} = i(-C\gamma^{(x4)})$, the matrix is built as sympy's imaginary unit `sp.I` times the whole-number matrix $-C\gamma^{(x4)}$ (`.tolist()` turns the numpy array into a list of rows, which `sp.Matrix` accepts). `charpoly(lam)` computes $\det(\lambda 1 - B)$ exactly, `.as_expr()` writes it as an ordinary expression, and `sp.factor` writes it as a product of factors. The printed result is `(lam - 1)**8*(lam + 1)**8`, sympy's way of writing $(\lambda - 1)^8(\lambda + 1)^8$.

```
detail = VERDICTS[("python", "B_hermitian_involution_signature")][1]
check_reproduces(sp.expand(polynomial - (lam - 1) ** 8 * (lam + 1) ** 8) == 0
                 and f"= {polynomial}" in detail
                 and recorded("wolfram", "B_signature_8_8"),
                 "det(lam 1 - B) = (lam - 1)^8 (lam + 1)^8: signature (8, 8)",
                 record=record_of("python", "B_hermitian_involution_signature"))
```

`detail` is the detail text of the recorded check, which states the polynomial. The check requires that the difference between the computed polynomial and $(\lambda-1)^8(\lambda+1)^8$ multiplies out (`sp.expand`) to exactly 0, and that the text `= (lam - 1)**8*(lam + 1)**8` occurs in the recorded detail (`in` tests whether one string occurs in another): the notebook and the record wrote the same polynomial, character by character.

In [18], how B moves past the gammas.

```
signs_B = {x: commutation_sign(B, gamma[x]) for x in COORDS}
commute = [x for x in COORDS if signs_B[x] == 1]
anticommute = [x for x in COORDS if signs_B[x] == -1]
say("B commutes with gamma^(x) for x = " + ", ".join(commute))
say("B anticommutes with gamma^(x) for x = " + ", ".join(anticommute))
check_reproduces(commute == ["x0", "x1", "x2", "x3", "x4"]
                 and anticommute == ["x5", "x6", "x7"]
                 and recorded("python", "B_gamma_relations"),
                 "B commutes with gamma^a for a = x0, x1, x2, x3, x4 and anticommutes "
                 "for x5, x6, x7",
                 record=record_of("python", "B_gamma_relations"))
```

The sign of B with each gamma is computed and the directions are sorted into two lists. The printed lines and the check confirm (B5): B anticommutes exactly with the gammas of the three extra times.

In [19], the picture of B.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
heat_map(axes[0], gamma["x4"], r"$\gamma^{(x4)}$ (antisymmetric)")
heat_map(axes[1], C @ gamma["x4"], r"$C\gamma^{(x4)}$ (antisymmetric)",
         row_label=False)
image = heat_map(axes[2], B.imag, r"imaginary part of $B = -iC\gamma^{(x4)}$",
                 row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "b_matrix",
            ...)
```

Three heat maps: $\gamma^{(x4)}$, $C\gamma^{(x4)}$ and the imaginary part of B (`B.imag`), which is $-C\gamma^{(x4)}$. In `05a_4_b_matrix.png` every picture changes colour when it is mirrored about its diagonal: all three are antisymmetric, and B, being i times an antisymmetric real matrix, is Hermitian.

In [20], the spectra.

```
TARGETS = [1, -1, 1j, -1j]  # the four possible eigenvalues
TARGET_NAMES = ["+1", "-1", "+i", "-i"]
matrices = {f"gamma^({x})": gamma[x] for x in COORDS}
matrices.update({"C": C, "Gamma": Gamma, "B": B})
counts = {}  # name -> [how many eigenvalues near +1, -1, +i, -i]
for name, m in matrices.items():
    eigenvalues = np.linalg.eigvals(m.astype(complex))
    counts[name] = [int(np.sum(np.abs(eigenvalues - z) < 1e-9)) for z in TARGETS]
    say(f"{name:12} " + "  ".join(f"{n}: {c}" for n, c in
                                   zip(TARGET_NAMES, counts[name])))
```

`matrices` collects the eleven matrices under their names (`update` adds three more entries). For each, `np.linalg.eigvals` computes its 16 eigenvalues as complex floating-point numbers, and the list comprehension counts how many lie within 10^{-9} of each of $+1$, -1, $+i$, $-i$ (for a complex number `np.abs` is its distance from 0). `{name:12}` pads the name to 12 characters, so that the eleven printed lines form a table.

```
predicted = {name: ([8, 8, 0, 0] if name in ("C", "Gamma", "B")
                    or ETA[name[7:9]] == 1 else [0, 0, 8, 8]) for name in matrices}
check(counts == predicted and all(np.trace(gamma[x]) == 0 for x in COORDS),
      "eigenvalues: +1 and -1 eight times each for the space-like gammas, C, Gamma "
      "and B; +i and -i eight times each for the time-like gammas")
```

The prediction of Rule 6: eight $+1$ and eight -1 for C, Γ, B and the space-like gammas, eight $+i$ and eight $-i$ for the time-like ones. For a gamma, `name[7:9]` cuts the two characters at positions 7 and 8 out of a name such as `gamma^(x1)`, which are `x1`; the `or` looks at it only when the name is not one of the three (Python evaluates `a or b` from the left and stops when `a` is true). The check compares all counts with the prediction and checks that every gamma has trace 0, the condition of Rule 6.

In [21], the picture of the spectra.

```
from matplotlib.colors import LinearSegmentedColormap as Ramp

names = list(matrices)  # the 11 matrices in the order of the table
table = np.array([counts[name] for name in names])  # 11 rows, 4 columns
COUNT_COLORS = Ramp.from_list("counts", ["#f0efec", "#2a78d6"])  # 0 grey, 8 blue
fig, ax = plt.subplots(figsize=(6.0, 6.4))
ax.imshow(table, cmap=COUNT_COLORS, vmin=0, vmax=8, aspect="auto")
for k in range(1, table.shape[0]):  # white gaps between the rows
    ax.axhline(k - 0.5, color="white", linewidth=2)
for k in range(1, table.shape[1]):  # and between the columns
    ax.axvline(k - 0.5, color="white", linewidth=2)
```

The table of counts becomes an array of 11 rows and 4 columns and is drawn as coloured squares, grey for 0 and blue for 8 (`as Ramp` gives the imported name a shorter name; `aspect="auto"` lets the squares be stretched to fill the picture). White lines between the rows and columns separate the squares.

```
for r in range(table.shape[0]):
    for c in range(table.shape[1]):
        ax.text(c, r, str(table[r, c]), ha="center", va="center",
                color="white" if table[r, c] == 8 else "black")
ax.set_xticks(range(4), ["$+1$", "$-1$", "$+i$", "$-i$"])
labels = [rf"$\gamma^{{({x})}}$" for x in COORDS] + ["$C$", r"$\Gamma$", "$B$"]
ax.set_yticks(range(len(names)), labels)
ax.set_xlabel("eigenvalue")
ax.set_title("How many times each eigenvalue occurs (16 in each row)")
ax.grid(False)
save_figure(fig, "spectra",
            ...)
```

`ax.text(c, r, ...)` writes each count in the middle of its square (`ha` and `va` centre it horizontally and vertically), in white on blue and in black on grey. The column labels are the four eigenvalues; the row labels are made by an `rf`-string, raw and formatted at once, in which a doubled brace `{{` stands for a single brace in the result, so that `$\gamma^{(x1)}$` and so on come out. The figure `05a_5_spectra.png` shows blue squares with 8 in the columns $+1$ and -1 for the space-like gammas, C, Γ and B, and in the columns $+i$ and $-i$ for the time-like gammas.

In [22], the table of commutation signs.

```
rows = {"C": signs_C, "Gamma": {x: commutation_sign(Gamma, gamma[x]) for x in COORDS},
        "B": signs_B}
sign_table = np.array([[rows[name][x] for x in COORDS] for name in rows])
expected_table = np.array([[-ETA[x] for x in COORDS], [-1] * 8,
                           [1, 1, 1, 1, 1, -1, -1, -1]])
check(np.array_equal(sign_table, expected_table),
      "the commutation signs of C, Gamma and B with the eight gammas are as predicted")
```

The signs of C (In [9]), of Γ (computed here) and of B (In [18]) with the eight gammas form a table of 3 rows and 8 columns. The predicted table has the rows $-\eta_{aa}$ (C1), eight times -1 (X2) and the pattern of (B5). The check compares them.

```
fig, ax = plt.subplots(figsize=(8.0, 3.2))
ax.imshow(sign_table, cmap=SIGNS, vmin=-1, vmax=1, aspect="auto")
for k in range(1, 3):  # white gaps between the rows
    ax.axhline(k - 0.5, color="white", linewidth=2)
for k in range(1, 8):  # and between the columns
    ax.axvline(k - 0.5, color="white", linewidth=2)
for r in range(3):
    for c in range(8):
        ax.text(c, r, f"{sign_table[r, c]:+d}", ha="center", va="center",
                color="white", fontweight="bold")
ax.set_xticks(range(8), [rf"$\gamma^{{({x})}}$" for x in COORDS])
ax.set_yticks(range(3), ["$C$", r"$\Gamma$", "$B$"])
ax.set_title(r"Sign $s$ in $M\gamma^a = s\,\gamma^a M$ (red $+1$ commute, "
             r"blue $-1$ anticommute)")
ax.grid(False)
save_figure(fig, "commutation_signs",
            ...)
```

The drawing works as in In [21], with the colour map of the heat maps: red squares $+1$ (commute), blue squares -1 (anticommute), each with its sign written in bold white. In `05a_6_commutatio n_signs.png` the row C is blue for $x0$, $x1$, $x2$, $x3$ and red for $x4$ to $x7$; the row Γ is blue everywhere; the row B is blue only for the extra times $x5$, $x6$, $x7$.

In [23], the last check.

```
FIGURES = ["05a_1_c_matrix.png", "05a_2_c_form_signs.png", "05a_3_chirality.png",
           "05a_4_b_matrix.png", "05a_5_spectra.png", "05a_6_commutation_signs.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the six figure files of notebook 05a exist")
all_checks_passed()
```

The cell checks that the six figure files exist and prints the last line, ALL 26 CHECKS PASSED (notebook 05a). The 26 checks are: one in In [3], one in In [4], two in In [5], three in In [7], three in In [9], one in In [10], two in In [11], four in In [13], two in In [14], two in In [16], and one each in In [17], In [18], In [20], In [22] and In [23]. The cells In [1], In [2], In [6], In [8], In [12], In [15], In [19] and In [21] check nothing.

5.11 Groups and representations from zero

This section introduces the words of group theory that the rest of the chapter needs, each with a proof of the one fact used later. All groups here are groups of matrices.

Group. A **group** of $n \times n$ matrices is a set G of invertible matrices that contains the identity, the product of any two of its members and the inverse of each member. Examples: the two matrices $\{1, -1\}$; all invertible $n \times n$ matrices; the rotations of the plane $R(\varphi) = \begin{pmatrix} \cos\varphi & -\sin\varphi \\ \sin\varphi & \cos\varphi \end{pmatrix}$, because $R(\varphi)R(\psi) = R(\varphi + \psi)$ (the addition theorems of sine and cosine) and $R(\varphi)^{-1} = R(-\varphi)$. A **subgroup** is a subset that is itself a group. The group **generated** by some matrices is the set of all finite products of these matrices and of their inverses; it is the smallest group that contains them.

Representation. A group of 16×16 matrices acts on columns of 16 numbers by multiplication, $\Psi \to g\Psi$. One says that the 16 components **carry a representation** of the group. A **subspace** is a set of columns that contains every sum and every multiple of its members (for example all columns whose components 9 to 16 are zero). A subspace W is **invariant** when gw lies in W for every g of the group and every w of W. The zero subspace $\{0\}$ and the set of all columns are always invariant. The representation is **irreducible** when there is no other invariant subspace: the 16 components cannot be cut into smaller pieces that the group keeps apart.

Span. A **combination** of matrices $M_1, \ldots, M_N$ is $c_1 M_1 + \cdots + c_N M_N$ with numbers c_j; the **span** is the set of all combinations. The matrices are **linearly independent** when no one of them is a combination of the others; then their span has **dimension** N. Writing each 16×16 matrix as one row of 256 numbers, N matrices are independent exactly when the N rows have **rank** N (the rank of a list of rows is the number of independent ones among them).

Commutant, intertwiner, equivalence. The **commutant** of a list of matrices is the set of all matrices X that commute with every matrix of the list. Two groups (or lists) of matrices $g \to \rho_1(g)$ and $g \to \rho_2(g)$, labelled by the same elements g, have an **intertwiner** T when $T\rho_1(g) = \rho_2(g)T$ for every g; they are **equivalent** when an invertible intertwiner exists, because then $\rho_2(g) = T\rho_1(g)T^{-1}$ and the two are the same matrices written in another basis.

Lemma 1. For an intertwiner T, the set of columns v with $Tv = 0$ (its **kernel**) is invariant under ρ_1, and the set of columns Tv (its **image**) is invariant under ρ_2. Proof: if $Tv = 0$, then $T\rho_1(g)v = \rho_2(g)Tv = 0$, so $\rho_1(g)v$ lies in the kernel; and $\rho_2(g)(Tv) = T(\rho_1(g)v)$ lies in the image.

Lemma 2 (Schur's lemma). An intertwiner T between two irreducible representations is either zero or invertible. Proof: by Lemma 1 and irreducibility, the kernel of T is $\{0\}$ or everything, and so is its image. If $T \neq 0$, the kernel is not everything, so it is $\{0\}$: T maps different columns to different columns. And the image is not $\{0\}$, so it is everything: every column is reached. A matrix with both properties is invertible.

Lemma 3 (span criterion). If the matrices of a group G of $n \times n$ matrices span all $n \times n$

matrices, then (a) the representation is irreducible, and (b) its commutant consists of the multiples of the identity. Proof of (a): let $W \neq \{0\}$ be invariant and $w \neq 0$ a column of W. An invariant subspace is mapped into itself by every combination of group matrices (each term maps w into W, and W contains sums and multiples), hence by every matrix. For any column v, the matrix $M = v\,w^T/(w^T w)$ (the column v times the row w^T, divided by the number $w^T w > 0$; for complex columns use $w^\dagger$) satisfies $Mw = v$. So v lies in W, and W is everything. Proof of (b): a matrix X that commutes with every group matrix commutes with every combination of them, hence with every matrix, in particular with the matrix E_{rc} that has a single 1 in row r and column c. The entry (i, j) of XE_{rc} is X_{ir} when $j = c$ and 0 otherwise; that of $E_{rc}X$ is X_{cj} when $i = r$ and 0 otherwise. Taking $j = c$ and $i \neq r$: $X_{ir} = 0$, so every entry off the diagonal is zero. Taking $i = r$ and $j = c$: $X_{rr} = X_{cc}$, so all diagonal entries are equal. So X is a number times 1.

Lemma 4 (two blocks). Suppose the matrices of a group of 16×16 matrices span exactly the block-diagonal matrices $\mathrm{diag}(X, Y)$, with X and Y any two 8×8 matrices. Then (a) the first half (components 1 to 8) and the second half (9 to 16) are invariant subspaces; (b) each half is irreducible; (c) the two halves are inequivalent; (d) the commutant has dimension 2 and is spanned by $P_- = \mathrm{diag}(1_8, 0)$ and $P_+ = \mathrm{diag}(0, 1_8)$. Proof: (a) a block-diagonal matrix maps a column with zeros in one half to a column with zeros in the same half. (b) On the first half the group acts by the blocks X, which span all 8×8 matrices; Lemma 3 applies, and the same for Y. (c) Let T be an 8×8 intertwiner, $TX = YT$ for every group element. The equation then holds for every combination, hence for every pair (X, Y) of 8×8 matrices (the span contains $\mathrm{diag}(X, Y)$ for all X and Y independently). Take $X = 1_8$ and $Y = 0$: $T = 0$. The only intertwiner is zero, so the halves are inequivalent. (d) Write a 16×16 matrix in blocks, $Z = \begin{pmatrix} W & U \\ V & R \end{pmatrix}$. Then

$$\mathrm{diag}(X, Y)\, Z = \begin{pmatrix} XW & XU \\ YV & YR \end{pmatrix}, \qquad Z\,\mathrm{diag}(X, Y) = \begin{pmatrix} WX & UY \\ VX & RY \end{pmatrix}.$$

Z commutes with all of them when W commutes with every X (so $W = w1_8$ by Lemma 3(b)), R with every Y (so $R = r1_8$), and $XU = UY$ and $YV = VX$ for all X, Y (so $U = V = 0$, by the argument of (c)). Hence $Z = wP_- + rP_+$: a space of dimension 2.

The negative control. If instead the second half carried a copy of the first ($Y = X$ always), the commutant would contain every $\begin{pmatrix} p1_8 & q1_8 \\ s1_8 & t1_8 \end{pmatrix}$, which commutes with every $\mathrm{diag}(X, X)$: dimension 4. So the commutant dimension 2 distinguishes two inequivalent halves (dimension 2) from two equivalent ones (dimension 4); Notebook 05b computes both.

Real or complex numbers. All the equations of this chapter for an unknown matrix have whole-number coefficients. Gaussian elimination, which finds their solutions, uses only addition, subtraction, multiplication and division of the coefficients, so it takes exactly the same steps whether the unknowns are allowed to be rational, real or complex numbers. The dimension of the space of solutions is therefore the same in all three cases, and the irreducibility proved below holds over the real and over the complex numbers.

5.12 Pin(4,4), Spin(4,4) and the generators S^{ab}

Vectors in the algebra. A **vector** is a list of eight real numbers $v = (v_{x0}, \dots, v_{x7})$. To it belongs the matrix $\gamma(v) = \sum_a v_a \gamma^a$, and two vectors have the **metric product** $\eta(u, v) = \sum_a \eta_{aa} u_a v_a$. From the Clifford relation, line by line:

$$\gamma(u)\gamma(v) + \gamma(v)\gamma(u) = \sum_{a,b} u_a v_b \, (\gamma^a \gamma^b + \gamma^b \gamma^a) = \sum_{a,b} u_a v_b \, 2\eta^{ab} 1 = 2\eta(u, v)\, 1.$$

The first step multiplies out both products and collects the terms with the same pair (a, b); the second is the Clifford relation; the third keeps only the terms $a = b$ (where $\eta^{aa} = \eta_{aa}$). With $u = v$: $\gamma(v)\gamma(v) = \eta(v, v)\, 1$. A vector with $\eta(u, u) = +1$ or -1 is a **unit vector**. For a unit vector, $\gamma(u)$ is invertible with $\gamma(u)^{-1} = \eta(u, u)\, \gamma(u)$, because $\gamma(u)\, \eta(u, u)\gamma(u) = \eta(u, u)^2\, 1 = 1$. (A **null** vector, such as $e_{x1} + e_{x4}$ with $\eta = 1 - 1 = 0$, has $\gamma(v)\gamma(v) = 0$ and no inverse; it is excluded.)

O(4,4) and SO(4,4). The real 8×8 matrices Λ that keep the metric product, $\eta(\Lambda u, \Lambda v) = \eta(u, v)$ for all u, v, are those with $\Lambda^T \eta \Lambda = \eta$; they form the group **O(4,4)**. Taking the determinant of both sides, $(\det \Lambda)^2 \det \eta = \det \eta$, and $\det \eta = (+1)^4(-1)^4 = 1$, so $\det \Lambda = \pm 1$. Those with $\det \Lambda = +1$ form the subgroup **SO(4,4)**.

Reflections. For a unit vector u, the **reflection** along u is the 8×8 matrix R_u with

$$R_u v = v - 2\, \frac{\eta(u, v)}{\eta(u, u)}\, u.$$

It sends u to $u - 2u = -u$ and keeps every w with $\eta(u, w) = 0$. These w form a 7-dimensional subspace that does not contain u, so in a basis made of u and seven such w the matrix is $\mathrm{diag}(-1, 1, \dots, 1)$, and $\det R_u = -1$. It keeps the metric product: expanding $\eta(R_u v, R_u w)$ gives $\eta(v, w)$ plus three terms with the factor $\eta(u, v)\eta(u, w)/\eta(u, u)$ and the coefficients -2, -2 and $+4$, which add up to zero. So R_u lies in O(4,4) but not in SO(4,4).

The key identity. For a unit vector u and any vector v:

$$-\gamma(u)\gamma(v)\gamma(u)^{-1} = \gamma(R_u v).$$

Proof, line by line. By the relation above, $\gamma(u)\gamma(v) = 2\eta(u, v)1 - \gamma(v)\gamma(u)$. Multiply from the right by $\gamma(u)^{-1}$:

$$\gamma(u)\gamma(v)\gamma(u)^{-1} = 2\eta(u, v)\, \gamma(u)^{-1} - \gamma(v) = 2\eta(u, v)\, \eta(u, u)\, \gamma(u) - \gamma(v).$$

Since $\eta(u, u) = \pm 1$, $\eta(u, u) = 1/\eta(u, u)$, and γ is linear ($\gamma(v) - c\,\gamma(u) = \gamma(v - cu)$), so the right side is $-\gamma(v - 2\eta(u, v)u/\eta(u, u)) = -\gamma(R_u v)$. Multiplying by -1 gives the identity. **Conjugation by a unit vector is a reflection, up to the sign.**

Pin(4,4) and Spin(4,4). Pin(4,4) is the set of all products

$$g = \gamma(u_1)\gamma(u_2) \cdots \gamma(u_k)$$

of finitely many unit vectors ($k = 0, 1, 2, \ldots$; the empty product is 1). It is a group: the product of two such products is again one, and the inverse $g^{-1} = \gamma(u_k)^{-1} \cdots \gamma(u_1)^{-1}$ is one too, because $\gamma(u)^{-1} = \gamma(\eta(u,u)u)$ and $\eta(u,u)u$ is a unit vector. **Spin(4,4)** is the subgroup of the products with an **even** number k of factors. Examples: every $\gamma^a = \gamma(e_a)$ lies in Pin(4,4), where e_a is the basic unit vector of the direction a; so does every product of different gammas, and it lies in Spin(4,4) when it is even. In particular C (four factors), Γ (eight), $1 = \gamma^{(x1)}\gamma^{(x1)}$ and $-1 = \gamma^{(x4)}\gamma^{(x4)}$ lie in Spin(4,4).

Even and odd are well defined. Multiply out a product of k vectors: each $\gamma(u_j)$ is a combination of single gammas, so the product is a combination of products of k gammas. Each such product can be brought into the order $x0, \ldots, x7$ by exchanging neighbours (a sign each time) and then shortened by $\gamma^a\gamma^a = \eta_{aa}1$, which removes two factors at a time. So the product is a combination of products of different gammas whose degrees have the same parity (evenness or oddness) as k. Section 5.13 shows that the 256 products of different gammas are linearly independent; so a nonzero matrix cannot be both a combination of even products and a combination of odd products. An element of Pin(4,4) is invertible, hence not zero, so it is either **even** or **odd**, never both.

The vector matrix. For g in Pin(4,4) put $\alpha(g) = g$ if g is even and $\alpha(g) = -g$ if it is odd (the **twisted** action). For a single unit vector the key identity reads $\alpha(\gamma(u))\,\gamma^c\,\gamma(u)^{-1} = \gamma(R_u e_c) = \sum_d (R_u)_{dc}\gamma^d$. For a product, $\alpha(gh) = \alpha(g)\alpha(h)$, and

$$\alpha(gh)\gamma^c(gh)^{-1} = \alpha(g)\big[\alpha(h)\gamma^c h^{-1}\big]g^{-1} = \sum_d \Lambda(h)_{dc}\,\alpha(g)\gamma^d g^{-1} = \sum_e \big(\Lambda(g)\Lambda(h)\big)_{ec}\gamma^e,$$

where $\Lambda(g)$ is the 8×8 matrix with $\alpha(g)\gamma^c g^{-1} = \sum_d \Lambda(g)_{dc}\gamma^d$. So $\Lambda(gh) = \Lambda(g)\Lambda(h)$, and for $g = \gamma(u_1)\cdots\gamma(u_k)$:

$$\Lambda(g) = R_{u_1}R_{u_2}\cdots R_{u_k},$$

a product of k reflections. It lies in O(4,4), with $\det\Lambda(g) = (-1)^k$: the even elements, those of Spin(4,4), have vector matrices in SO(4,4). The matrix $\Lambda(g)$ says how g moves the eight directions; it is called the **vector matrix** of g. Section 5.18 shows that g and $-g$ have the same vector matrix and that these are the only two (the **double cover**).

The generators. For two directions a and b the **scaled commutator**

$$S^{ab} = \tfrac{1}{4}[\gamma^a, \gamma^b] = \tfrac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$$

is called a **generator**. $S^{aa} = 0$ and $S^{ba} = -S^{ab}$. For $a \neq b$ the two gammas anticommute, so $\gamma^a\gamma^b - \gamma^b\gamma^a = 2\gamma^a\gamma^b$ and $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$: its entries are 0 and $\pm\frac{1}{2}$. With a before b in the order $x0, \ldots, x7$ there are $8 \cdot 7/2 = 28$ generators, one for each **coordinate plane** (a, b). When $\eta_{aa}\eta_{bb} = +1$ (both directions space-like, or both time-like) the plane is called a **rotation** plane: $\binom{4}{2} + \binom{4}{2} = 6 + 6 = 12$ of them. When $\eta_{aa}\eta_{bb} = -1$ (one space-like and one time-like direction) it is a **boost** plane: $4 \cdot 4 = 16$ of them. Note that a plane of two times, such as $(x4, x5)$, is a rotation plane.

The vector rule. For all a, b, c:

$$[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b.$$

Proof for $a \neq b$ (for $a = b$ both sides are zero). Use the Clifford relation first as $\gamma^b\gamma^c = 2\eta^{bc}1 - \gamma^c\gamma^b$ and then as $\gamma^a\gamma^c = 2\eta^{ac}1 - \gamma^c\gamma^a$:

$$\gamma^a\gamma^b\gamma^c = 2\eta^{bc}\gamma^a - \gamma^a\gamma^c\gamma^b = 2\eta^{bc}\gamma^a - 2\eta^{ac}\gamma^b + \gamma^c\gamma^a\gamma^b.$$

Hence $[\gamma^a\gamma^b, \gamma^c] = \gamma^a\gamma^b\gamma^c - \gamma^c\gamma^a\gamma^b = 2\eta^{bc}\gamma^a - 2\eta^{ac}\gamma^b$, and dividing by 2 gives the rule. It says that a generator turns the gammas into combinations of each other, as an infinitesimal turning of the directions turns the components of a vector: in the plane $(x1, x2)$, $[S^{(x1)(x2)}, \gamma^{(x1)}] = -\gamma^{(x2)}$ and $[S^{(x1)(x2)}, \gamma^{(x2)}] = \gamma^{(x1)}$, and every other gamma commutes with $S^{(x1)(x2)}$.

5.13 Irreducible under Pin(4,4), two inequivalent halves under Spin(4,4)

The author's statement about the field dirac16complex is that its 16 components transform under a 16-dimensional irreducible representation of Pin(4,4), and, for the transformations of determinant 1, under a direct sum of two inequivalent 8×8 irreducible representations of Spin(4,4). This section proves both halves of the statement.

From a matrix equation to linear equations. Every statement below is about an unknown matrix X that obeys equations such as $\gamma^a X = X\gamma^a$. Let X be an unknown $n \times m$ matrix, L a known $n \times n$ matrix and R a known $m \times m$ matrix. The entry (r, c) of $LX - XR$ is

$$(LX)_{rc} - (XR)_{rc} = \sum_k L_{rk}X_{kc} - \sum_k X_{rk}R_{kc}.$$

So $LX - XR = 0$ is a list of nm **linear equations** for the nm entries of X: in the equation (r, c) the unknown X_{kc} has the coefficient L_{rk} and the unknown X_{rk} the coefficient $-R_{kc}$. Listing the unknowns row by row $(X_{11}, X_{12}, \dots)$, these coefficients form the matrix

$$A = \mathrm{kron}(L, 1_m) - \mathrm{kron}(1_n, R^T),$$

with one row per equation and one column per unknown; $\mathrm{kron}(P, Q)$, the **Kronecker product**, is the big matrix whose block in block row r and block column k is P_{rk} times the whole matrix Q.

For a list of equations (for example one for each of the eight gammas) the coefficient matrices are stacked on top of each other. The solutions form a space of dimension (number of unknowns) minus (rank of A). The rank can be computed **exactly** by Gaussian elimination with fractions, without any rounding.

A second, independent engine. For the coefficient matrix A, the matrix $N = A^T A$ is symmetric, and $Ny = 0$ exactly when $Ay = 0$: if $Ny = 0$, then $0 = y^T Ny = (Ay)^T(Ay)$, which is the sum of the squares of the entries of Ay, so $Ay = 0$; the converse is clear. So the dimension of the solution space equals the number of zero eigenvalues of N, which a floating-point eigenvalue program computes independently of the exact elimination.

Theorem P (Pin(4,4) is irreducible). The 16 components carry an irreducible representation of Pin(4,4), and only the multiples of 1 commute with every element of Pin(4,4).

Proof, step by step.

- Step 1: the span of Pin(4,4) is the span of the 256 products of different gammas. Every product of different gammas is a product of unit vectors $\gamma(e_a)$, hence an element of Pin(4,4). Conversely, every element of Pin(4,4) is, by the multiplication argument of Section 5.12, a combination of products of different gammas.
- Step 2: the 256 products of different gammas are linearly independent. This is an exact computation: the 256×256 matrix of their entries has rank 256 (Revision record and Notebook 05b). 256 independent 16×16 matrices span the space of all 16×16 matrices, which has dimension 256.
- Step 3: by Lemma 3 of Section 5.11, the representation is irreducible and its commutant consists of the multiples of 1.

The second engine confirms the commutant directly: the $8 \times 256 = 2048$ equations $\gamma^a X - X\gamma^a = 0$ ($a = x0, \ldots, x7$) have rank 255, so their solutions form a space of dimension $256 - 255 = 1$, the multiples of 1. (A matrix that commutes with the eight gammas commutes with all their products and combinations, hence with all of Pin(4,4); the converse holds because every gamma is in Pin(4,4).)

Theorem S (two inequivalent halves under Spin(4,4)). Under Spin(4,4) the 16 components split into the two chiral halves of 8 components (Section 5.5); each half carries an irreducible representation of Spin(4,4); the two are inequivalent; and the commutant of Spin(4,4) is spanned by P_- and P_+.

Proof, step by step.

- Step 1: the span of Spin(4,4) is the span of the 128 even products of different gammas, by the argument of Theorem P restricted to even products (Section 5.12: an even element is a combination of even products; every even product of different gammas is an even element).
- Step 2: every even product is block diagonal (the block rule of Section 5.5), and the 128 even products are linearly independent (exact rank 128). The block-diagonal matrices $\mathrm{diag}(X, Y)$ form a space of dimension $64 + 64 = 128$. So the even products span exactly all block-diagonal matrices.
- Step 3: Lemma 4 of Section 5.11 gives all four claims.

The same with the 28 generators. The Revision record and Notebook 05b also compute the commutant of the 28 generators S^{ab}: dimension 2, spanned by P_- and P_+; on each half the commutant of the 28 blocks has dimension 1; and the equations for an intertwiner between the halves have only the solution 0. A matrix commutes with every exponential $\exp(\theta S^{ab})$ (Section 5.18) exactly when it commutes with every S^{ab} (take the derivative at $\theta = 0$ in one direction; in the other, a matrix that commutes with S commutes with every power of S and hence with the power series of the exponential). So these numbers show that the conclusions of Theorem S hold already for the part of Spin(4,4) made of products of exponentials, which Section 5.23 calls $\mathrm{Spin}_0(4,4)$.

Why Pin(4,4) sees one block of 16. Every gamma is an odd element of Pin(4,4), and every gamma exchanges the two halves (Section 5.5). So neither half is invariant under Pin(4,4): the two inequivalent halves of Spin(4,4) are joined by the reflections into one irreducible representation of Pin(4,4).

Imposing the gammas one at a time. How large is the commutant of only the first j gammas? With no condition all 256 entries are free. The first gamma in the order $x0, \ldots, x7$ is $\gamma^{(x0)}$. The matrices that commute with $\gamma^{(x0)}$ are those that map each of its two eigenspaces into itself: if $\gamma v = \lambda v$ and $X\gamma = \gamma X$, then $\gamma(Xv) = X\gamma v = \lambda Xv$, so Xv has the same eigenvalue; conversely a matrix that acts separately on the two eigenspaces commutes with γ. A real symmetric matrix has a basis of eigenvectors, and $\gamma^{(x0)}$ (space-like, hence symmetric) has eight eigenvalues $+1$ and eight -1 (Section 5.3), so there are $8^2 + 8^2 = 128$ free entries. Notebook 05b computes, exactly, that every further gamma halves the dimension again: $256, 128, 64, 32, 16, 8, 4, 2, 1$. (Only the first step is proved here; the whole sequence is COMPUTED.)

5.14 Example: Notebook 05b computes the commutants

Notebook 05b turns every statement of Section 5.13 into a system of linear equations and computes its exact rank with sympy. It first tests the construction of the coefficient matrix on a random matrix and on a 2×2 warm-up that can be done by hand; then it computes the ranks of the 256 and of the 128 even products of different gammas, the commutant of the eight gammas, the commutants obtained by imposing the gammas one at a time, the commutant of the 28 generators, the commutants on each half, the intertwiners between the halves and the negative control with two equal halves. It confirms every dimension a second time with the zero eigenvalues of $A^T A$, and predicts all 256 eigenvalues of $A^T A$ for the eight gammas exactly. It draws five figures and ends with the line ALL 17 CHECKS PASSED (notebook 05b).

5.15 How to run Notebook 05b

Step 1. What this notebook does and what it needs.

Notebook 05b (Commutants: Pin(4,4) acts irreducibly, Spin(4,4) splits into two inequivalent halves) is the file `Revision/textbook/notebooks/05b_commutants.ipynb` of the repository Dirac_claude. It turns the matrix equations X M = M X into systems of linear equations for the 256 entries of an unknown 16 by 16 matrix X, solves them exactly, and so computes: the rank of the 256 Clifford products, the commutant of the eight gammas (dimension 1: the 16 components carry an irreducible representation of Pin(4,4)), the commutant of the 28 generators S^ab (dimension 2, spanned by the chiral projectors), the commutants of the two halves (1 and 1) and the intertwiners between them (0 and 0: inequivalent halves), with a negative control that shows what equivalent halves would give. Five teaching plots show the counts, the eigenvalues of the equation systems and the dimensions. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private

Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05b_commutants.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 25 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05b_commutants.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05b_commutants.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/05b.captions.json`
- `Revision/textbook/figures/05b_1_clifford_products.png`
- `Revision/textbook/figures/05b_2_system_eigenvalues.png`
- `Revision/textbook/figures/05b_3_commutant_halving.png`
- `Revision/textbook/figures/05b_4_spin_commutant.png`
- `Revision/textbook/figures/05b_5_dimensions.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the five figure files of notebook 05b exist
ALL 17 CHECKS PASSED (notebook 05b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/05b_commutants.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05b_commutants.ipynb
python -m nbconvert --execute --inplace 05b_commutants.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming `Revision/algebra/gammas.json`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.
- the cells of sections 10 and 11 take much longer than a few seconds: they solve 7168 linear equations exactly; on a slow computer they may take a minute. Wait until the star in the brackets left of the cell turns into a number.

5.16 Notebook 05b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05b_commutants.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The 16 components of the author's spinor field are acted on by two groups of
$16 \times 16$ matrices: **Pin(4,4)**, made of products of gamma matrices, and its
subgroup **Spin(4,4)**, made of products of an *even* number of them. The Revision
record states, and this notebook verifies with its own exact computation:
```

1. the $2^8 = 256$ products of different gammas are linearly independent, so they span all 16×16 matrices;
2. only the multiples of the identity commute with all eight gammas (the *commutant* has dimension 1): the 16 components form an **irreducible** representation of Pin(4,4);
3. the matrices that commute with all 28 generators S^{ab} of Spin(4,4) form a space of dimension 2, spanned by the two chiral projectors P_- and P_+: under Spin(4,4) the 16 components split into two halves of 8;
4. each half is irreducible (commutant dimension 1), and the two halves are **inequivalent**: the only matrix that carries one half into the other while respecting Spin(4,4) is zero.

The method is the same for every statement: a matrix equation such as $X\gamma^a = \gamma^a X$ for an unknown matrix X is a system of *linear equations* for the 256 entries of X, and the number of independent solutions is 256 minus the *rank* of the system. Every check that repeats a recorded check prints the record file and the check name. Five teaching plots show the counts and the dimensions; a negative control shows what the computation would give if the two halves were equivalent.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 05b (Commutants: Pin(4,4) acts irreducibly, Spin(4,4) splits into two inequivalent halves) is the file ‘Revision/textbook/notebooks/05b_commutants.ipynb‘ of the repository Dirac_claude. It turns the matrix equations X M = M X into systems of linear equations for the 256 entries of an unknown 16 by 16 matrix X, solves them exactly, and so computes: the rank of the 256 Clifford products, the commutant of the eight gammas (dimension 1: the 16 components carry an irreducible representation of Pin(4,4)), the commutant of the 28 generators S^ab (dimension 2, spanned by the chiral projectors), the commutants of the two halves (1 and 1) and the intertwiners between them (0 and 0: inequivalent halves), with a negative control that shows what equivalent halves would give. Five teaching plots show the counts, the eigenvalues of the equation systems and the dimensions. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the

default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
```

```
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 05b_commutants.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 25 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 05b_commutants.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05b_commutants.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05b.captions.json‘
- ‘Revision/textbook/figures/05b_1_clifford_products.png‘
- ‘Revision/textbook/figures/05b_2_system_eigenvalues.png‘
- ‘Revision/textbook/figures/05b_3_commutant_halving.png‘
- ‘Revision/textbook/figures/05b_4_spin_commutant.png‘
- ‘Revision/textbook/figures/05b_5_dimensions.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the

stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the five figure files of notebook 05b exist
ALL 17 CHECKS PASSED (notebook 05b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/05b_commutants.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 05b_commutants.ipynb
  python -m nbconvert --execute --inplace 05b_commutants.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands

  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming ‘Revision/algebra/gammas.json‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.
- the cells of sections 10 and 11 take much longer than a few seconds: they solve 7168 linear equations exactly; on a slow computer they may take a minute. Wait until the star in the brackets left of the cell turns into a number.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 05b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05b (Commutants: Pin(4,4) acts irreducibly, Spin(4,4) splits into two
# inequivalent halves) is the file Revision/textbook/notebooks/05b_commutants.ipynb of
# the repository Dirac_claude. It turns the matrix equations X M = M X into systems of
# linear equations for the 256 entries of an unknown 16 by 16 matrix X, solves them
# exactly, and so computes: the rank of the 256 Clifford products, the commutant of the
# eight gammas (dimension 1: the 16 components carry an irreducible representation of
# Pin(4,4)), the commutant of the 28 generators S^ab (dimension 2, spanned by the chiral
# projectors), the commutants of the two halves (1 and 1) and the intertwiners between
# them (0 and 0: inequivalent halves), with a negative control that shows what equivalent
# halves would give. Five teaching plots show the counts, the eigenvalues of the equation
# systems and the dimensions. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
```

```
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

```
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05b_commutants.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
```

```
# notebook has finished when the last code cell shows a number; this takes about 25
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05b_commutants.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 05b_commutants.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/05b.captions.json
# - Revision/textbook/figures/05b_1_clifford_products.png
# - Revision/textbook/figures/05b_2_system_eigenvalues.png
# - Revision/textbook/figures/05b_3_commutant_halving.png
# - Revision/textbook/figures/05b_4_spin_commutant.png
# - Revision/textbook/figures/05b_5_dimensions.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the five figure files of notebook 05b exist
#     ALL 17 CHECKS PASSED (notebook 05b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
```

```
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05b_commutants.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05b_commutants.ipynb
#     python -m nbconvert --execute --inplace 05b_commutants.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming Revision/algebra/gammas.json: the notebook was opened
#   outside the repository, or the repository is incomplete; clone the repository again
#   and open the notebook from its folder Revision/textbook/notebooks.
# - the cells of sections 10 and 11 take much longer than a few seconds: they solve 7168
#   linear equations exactly; on a slow computer they may take a minute. Wait until the
#   star in the brackets left of the cell turns into a number.

## 3. The words used in this notebook

- **Linear equation, system**: an equation of the form $c_1 y_1 + c_2 y_2 + \dots
  + c_n y_n = 0$ for unknown numbers $y_1, \dots, y_n$ with given coefficients
  $c_j$. A *system* is a list of such equations; its coefficients form the
  **coefficient matrix** $A$ (one row per equation), and the system reads
  $Ay = 0$.
- **Solution space, dimension**: the set of all solutions $y$ of $Ay = 0$. Sums
  and multiples of solutions are solutions. Its **dimension** is the number of
  solutions needed so that every solution is a combination of them (a
  **basis**).
- **Rank**: the number of independent rows of $A$ (rows that are not combinations
  of other rows). For $n$ unknowns: dimension of the solution space $= n -
  \text{rank}$.
- **Exact arithmetic**: computing with fractions, never rounding. The package
  sympy does this (`DomainMatrix` over `QQ`, the rational numbers).
- **Linearly independent matrices**: no one of them is a combination of the
  others. Writing each $16 \times 16$ matrix as one row of 256 numbers, $N$ matrices
  are independent when these $N$ rows have rank $N$.
- **Span**: all combinations of a list of matrices.
- **Clifford product**: a product $\gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ of
  $k$ *different* gammas, taken in the order $x0, \dots, x7$; $k$ is its
  **degree**; it is **even** or **odd** with $k$. The degree-0 product is $1$.
- **Group**: a set of invertible matrices that contains the products and the
  inverses of its members.
- **Representation, invariant subspace, irreducible**: a group of $16 \times 16$
  matrices *represents* the group on columns of 16 numbers. A set of columns that
  every group matrix maps into itself is *invariant*. The representation is
  **irreducible** when the only invariant subspaces are $\{0\}$ and everything.
- **Commutant**: all matrices $X$ that commute with every matrix of a list.
- **Intertwiner**: a matrix $X$ with $X M_k = N_k X$ for two lists of matrices
  $M_k$, $N_k$ (it carries the first representation into the second).
  **Equivalent** representations have an invertible intertwiner.
- **Schur's lemma** (used here, proved in the text): when the matrices of a
  representation span all matrices, the representation is irreducible and its
  commutant is the multiples of 1; an intertwiner between two irreducible
  representations is zero or invertible.
- **Generators** $S^{ab} = \tfrac14[\gamma^a, \gamma^b] = \tfrac14(\gamma^a\gamma^b
  - \gamma^b\gamma^a)$: the 28 matrices ($a < b$) from which every element of the
  part of Spin(4,4) connected to 1 is built as a product of exponentials
  $\exp(\theta S^{ab})$.
- **Chiral halves**: the components 1 to 8 (chirality $\Gamma = -1$) and 9 to 16
  ($\Gamma = +1$); $P_- = \mathrm{diag}(1_8, 0)$ and $P_+ = \mathrm{diag}(0, 1_8)$.
- **Kronecker product** `np.kron(L, R)`: the big matrix whose block in block row
  $r$ and block column $k$ is $L_{rk}$ times the whole matrix $R$.
```

Text cell:

```
## 4. The physical and mathematical situation

**From a matrix equation to linear equations.** Let $X$ be an unknown $n \times m$
matrix, $L$ a known $n \times n$ and $R$ a known $m \times m$ matrix, and consider
$LX - XR = 0$. List the $nm$ entries of $X$ row by row: $X_{11}, X_{12}, \dots,
X_{1m}, X_{21}, \dots$. The entry $(r, c)$ of the equation is

$$(LX)_{rc} - (XR)_{rc} = \sum_k L_{rk} X_{kc} - \sum_k X_{rk} R_{kc} = 0 .$$

In the first sum the unknown $X_{kc}$ has the coefficient $L_{rk}$; in the second
the unknown $X_{rk}$ has the coefficient $R_{kc}$. Collected over all $(r, c)$,
these coefficients form the matrix $\mathrm{kron}(L, 1_m) - \mathrm{kron}(1_n,
R^T)$, with one row per equation and one column per unknown. For a list of pairs
$(L_j, R_j)$ the coefficient matrices are stacked on top of each other. For the
commutant of the eight gammas: $n = m = 16$, $L_j = R_j = \gamma^{a}$, so
$8 \times 256 = 2048$ equations for 256 unknowns.

**How the two computations prove irreducibility.** Every element of Pin(4,4) is a
product of matrices $\gamma(u) = \sum_a u_a \gamma^a$, so it is a combination of
Clifford products; conversely every Clifford product is, up to a sign, an element
of Pin(4,4) (each $\gamma^a$ is one). So the span of Pin(4,4) is the span of the 256
Clifford products. *First computation*: if they span all $16 \times 16$ matrices,
then every invariant subspace is $\{0\}$ or everything (a subspace kept by every
matrix is $\{0\}$ or everything), and only the multiples of 1 commute with them
(Schur's lemma in its span form). *Second computation*: the commutant of the eight
gammas, solved directly; it confirms the second statement independently. For
Spin(4,4) the even products play the same role: if they span exactly the
block-diagonal matrices $\mathrm{diag}(X, Y)$, each half is irreducible and the two
halves are inequivalent (an intertwiner $T$ with $TX = YT$ for all $X$, $Y$ must
vanish: take $X = 1_8$, $Y = 0$). The commutant of the 28 generators $S^{ab}$, which
build the part of Spin(4,4) connected to 1, and the intertwiners between the two
halves are then computed directly, in the form in which the Revision record states
them.

**Two halves, equivalent or not.** If the 16 components split into two invariant
halves of 8 and each half is irreducible, the commutant has dimension 2 when the
halves are inequivalent ($X = p P_- + q P_+$) and dimension 4 when they are
equivalent (then a matrix that carries one half onto the other also commutes).
The notebook computes both the real case and an artificial *control* with two
equal halves.

**A second engine.** For a coefficient matrix $A$ the matrix $N = A^T A$ is
symmetric, and $Ny = 0$ exactly when $Ay = 0$: if $Ny = 0$, then
$0 = y^T N y = (Ay)^T(Ay) = |Ay|^2$, the sum of the squares of the entries of
$Ay$, so $Ay = 0$; the converse is clear. Hence the dimension of the solution space
equals the number of zero eigenvalues of $N$, which numpy computes in
floating-point numbers, independently of sympy.
```

Text cell:

```
## 5. The gammas and the recorded checks

The next cell reads the gammas from the record ‘Revision/algebra/gammas.json‘ (exact
```

whole numbers), reads the two Revision reports, and defines the helpers
‘recorded(key, name)‘ (true when the report ‘key‘, "python" or "wolfram", holds the
check ‘name‘ with the verdict pass), ‘detail(key, name)‘ (the detail text of that
check), ‘record_of(key, name)‘ (the text printed after "reproduces") and
‘check_reproduces(condition, name, record)‘, the helper ‘check‘ for a check that
reproduces a Revision record: it lets ‘check‘ print the PASS line and the line
"reproduces ..." into a text buffer (‘contextlib.redirect_stdout‘) and sends both
lines with one ‘sys.stdout.write‘, because Jupyter delivers printed text in pieces
and one piece keeps the two lines together for the tools that read the notebook.
Then it checks the Clifford relation, on which everything below rests.

In [2]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1

REPORT_FILES = {"python": "Revision/algebra/reports/python-algebra.json",
                "wolfram": "Revision/algebra/reports/wolfram-algebra.json"}
VERDICTS = {}  # (report key, check name) -> (verdict in lower case, detail text)
for key, path in REPORT_FILES.items():
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in report_data["checks"]:
        VERDICTS[(key, entry["name"])] = (entry["verdict"].lower(), entry["detail"])

def recorded(key, name):
    """True when the report key records the check name with the verdict pass."""
    return VERDICTS[(key, name)][0] == "pass"

def detail(key, name):
    """The detail text of the recorded check."""
    return VERDICTS[(key, name)][1]

def record_of(key, name):
    """The text printed after "reproduces": the record file and the check name."""
    return f"{REPORT_FILES[key]}, check {name}"

def check_reproduces(condition, name, record):
    """check(condition, name, record=record), printed in one piece."""
    collected = io.StringIO()
```

```
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together

clifford_ok = all(
    np.array_equal(gamma[x] @ gamma[y] + gamma[y] @ gamma[x],
                   2 * ETA[x] * I16 if x == y else 0 * I16)
    for x in COORDS for y in COORDS)
check_reproduces(clifford_ok and recorded("python", "clifford_relation"),
                 "{gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs",
                 record=record_of("python", "clifford_relation"))
```

Out [2]:

```
PASS {gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs
     reproduces Revision/algebra/reports/python-algebra.json, check clifford_relation
```

Text cell:

```
## 6. The tools: equation systems and their exact rank

The next cell defines three tools.

- ‘commutation_system(lefts, rights)‘ builds the coefficient matrix of the
  equations $L X - X R = 0$ for all pairs $(L, R)$ of the two lists, following
  section 4.
- ‘exact_rank(A)‘ computes the rank of a matrix of whole numbers exactly, with
  sympy’s ‘DomainMatrix‘ over the rational numbers ‘QQ‘ (Gaussian elimination with
  fractions).
- ‘solution_basis(A, n, m)‘ returns a basis of the solutions as $n \times m$
  matrices (sympy’s ‘nullspace‘, also exact).

Then the cell tests the construction: for a random matrix $X$ of whole numbers
(from a random-number generator with the fixed seed 12345, so every run uses the
same numbers), the coefficient matrix applied to the entries of $X$ must give the
entries of $LX - XR$.
```

In [3]:

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over QQ

def commutation_system(lefts, rights):
    """Coefficient matrix of L X - X R = 0 for every pair (L, R); X is n x m with
    n = size of L and m = size of R; the unknowns are the entries of X row by row."""
    blocks = []
    for L, R in zip(lefts, rights):
        n, m = L.shape[0], R.shape[0]
        blocks.append(np.kron(L, np.eye(m, dtype=np.int64))
```

```
                    - np.kron(np.eye(n, dtype=np.int64), R.T))
    return np.vstack(blocks)  # the blocks stacked on top of each other

def exact_rank(A):
    """The rank of the whole-number matrix A, computed exactly."""
    return DomainMatrix.from_list(A.tolist(), sp.QQ).rank()

def solution_basis(A, n, m):
    """A basis of all solutions of A y = 0, each reshaped to an n x m matrix."""
    null = DomainMatrix.from_list(A.tolist(), sp.QQ).nullspace().to_Matrix()
    return [np.array(null.row(k).tolist()[0], dtype=float).reshape(n, m)
            for k in range(null.rows)]

rng = np.random.default_rng(12345)  # random numbers with a fixed seed
X = rng.integers(-5, 6, size=(16, 16))  # a random 16 x 16 matrix, entries -5..5
L, R = gamma["x1"], gamma["x4"]
A = commutation_system([L], [R])
say(f"one pair (L, R) gives {A.shape[0]} equations for {A.shape[1]} unknowns")
check(np.array_equal(A @ X.reshape(256), (L @ X - X @ R).reshape(256)),
      "the coefficient matrix applied to X row by row gives L X - X R")
```

Out [3]:

```
one pair (L, R) gives 256 equations for 256 unknowns
PASS the coefficient matrix applied to X row by row gives L X - X R
```

Text cell:

```
**A warm-up with $2 \times 2$ matrices.** Which $2 \times 2$ matrices
$X = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$ commute with
$M = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$? By hand: $MX =
\begin{pmatrix} r & s \\ p & q \end{pmatrix}$ and $XM = \begin{pmatrix} q & p \\ s & r
\end{pmatrix}$, so $MX = XM$ means $r = q$ and $s = p$: the solutions are
$\begin{pmatrix} p & q \\ q & p \end{pmatrix}$, a space of dimension 2 (basis: the
identity and $M$ itself). The next cell gets the same answer from the tools: 4
equations, rank 2, dimension $4 - 2 = 2$.
```

In [4]:

```
M = np.array([[0, 1], [1, 0]], dtype=np.int64)
A_small = commutation_system([M], [M])  # 4 equations for the 4 entries p, q, r, s
rank_small = exact_rank(A_small)
basis_small = solution_basis(A_small, 2, 2)
say(f"coefficient matrix (rows = equations, columns = p, q, r, s):")
for row in A_small.tolist():
    say(f"    {row}")
say(f"rank {rank_small}; dimension of the solution space {4 - rank_small}")
for k, b in enumerate(basis_small, 1):
```

```
    say(f"basis solution {k}: rows {b.astype(int).tolist()}")
check(rank_small == 2 and len(basis_small) == 2,
      "warm-up: the 2 x 2 matrices commuting with M form a space of dimension 2")
```

Out [4]:

```
coefficient matrix (rows = equations, columns = p, q, r, s):
    [0, -1, 1, 0]
    [-1, 0, 0, 1]
    [1, 0, 0, -1]
    [0, 1, -1, 0]
rank 2; dimension of the solution space 2
basis solution 1: rows [[0, 1], [1, 0]]
basis solution 2: rows [[1, 0], [0, 1]]
PASS warm-up: the 2 x 2 matrices commuting with M form a space of dimension 2
```

Text cell:

```
## 7. The 256 Clifford products span all 16 x 16 matrices

The next cell builds the Clifford products of every degree $k = 0, \dots, 8$ (for
each $k$, ‘itertools.combinations‘ lists the $\binom{8}{k}$ subsets of $k$
directions in the order $x0, \dots, x7$). It writes each product as one row of 256
numbers and computes exactly the rank of all 256 rows (must be 256: independent),
of the 128 even ones (must be 128), and the rank after adding the products degree
by degree. It also checks that every even product is block diagonal (it maps each
half into itself) and every odd product block off-diagonal (it exchanges the
halves).
```

In [5]:

```
import itertools  # subsets of a given size
from math import comb  # comb(8, k): the number of subsets of size k

products = {}  # degree k -> list of the Clifford products of degree k
for k in range(9):
    products[k] = []
    for subset in itertools.combinations(COORDS, k):
        p = I16
        for x in subset:
            p = p @ gamma[x]
        products[k].append(p)
rows_all = np.array([p.reshape(256) for k in range(9) for p in products[k]])
rows_even = np.array([p.reshape(256) for k in (0, 2, 4, 6, 8) for p in products[k]])
rank_all, rank_even = exact_rank(rows_all), exact_rank(rows_even)
cumulative = []  # the rank after adding the degrees 0, 1, ..., k
for k in range(9):
    cumulative.append(exact_rank(np.array(
        [p.reshape(256) for j in range(k + 1) for p in products[j]])))
for k in range(9):
    say(f"degree {k}: {len(products[k]):2d} products (comb(8, {k}) = {comb(8, k):2d});"
```

```
        f" rank of all products up to degree {k}: {cumulative[k]}")
say(f"rank of all 256 products: {rank_all}; rank of the 128 even products: "
    f"{rank_even}")

```
**The second engine and what its eigenvalues mean.** The next cell computes the
eigenvalues of $N = A^T A$ ($256 \times 256$) with numpy and counts those below
$10^{-9}$: by section 4 their number is the dimension of the commutant. The
eigenvalues can even be predicted exactly. The equations for $\gamma^a$ act on $X$
as $X \to \gamma^a X - X\gamma^a$; the transposed equations act as $X \to
\eta_{aa}(\gamma^a X - X\gamma^a)$ (because $(\gamma^a)^T = \eta_{aa}\gamma^a$).
Take for $X$ a Clifford product $P$. If $\gamma^a$ commutes with $P$, the first
step gives 0. If it anticommutes, the first step gives $2\gamma^a P$, the second
$\eta_{aa}(2\gamma^a\gamma^a P - 2\gamma^a P\gamma^a) = \eta_{aa}(2\eta_{aa}P +
2\eta_{aa}P) = 4P$. So $NP = 4\, n(P)\, P$, where $n(P)$ is the number of gammas
that anticommute with $P$. By the sign rule for moving a gamma through $k$
different factors, $n(P) = k$ for even $k$ and $n(P) = 8 - k$ for odd $k$. The cell
checks $NP = 4n(P)P$ exactly for all 256 products and compares the predicted list
of eigenvalues with numpy's.

## 9. Imposing the gammas one at a time

How does the commutant shrink as more gammas are required to commute with $X$?
With no condition, all 256 entries are free. The matrices that commute with one
gamma, say $\gamma^{(x1)}$, are those that map each of its two eigenspaces
(eigenvalue $+1$ and $-1$, eight dimensions each) into itself: $8^2 + 8^2 = 128$
of them. The next cell computes the dimension after imposing $\gamma^{(x1)}$, then
also $\gamma^{(x2)}$, and so on up to all eight, exactly.
```

In [9]:

```
halving = [256]  # dimension of the commutant of the first j gammas, j = 0, 1, ..., 8

## 10. The generators S^ab and the commutant of Spin(4,4)

The next cell builds the 28 generators $S^{ab} = \tfrac14[\gamma^a, \gamma^b]$
($a$ before $b$ in the order $x0, \dots, x7$). For $a \neq b$ the two gammas
anticommute, so $[\gamma^a, \gamma^b] = 2\gamma^a\gamma^b$ and $S^{ab} =
\tfrac12\gamma^a\gamma^b$: its entries are $0$ and $\pm\tfrac12$. It checks these
recorded facts and that every $S^{ab}$ is block diagonal. For the exact equation
system it uses the whole-number matrices $2S^{ab} = \gamma^a\gamma^b$, which have
the same commutant (a matrix commutes with $S$ exactly when it commutes with $2S$).
```

In [10]:

```
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 pairs
S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4 for a, b in pairs}
```

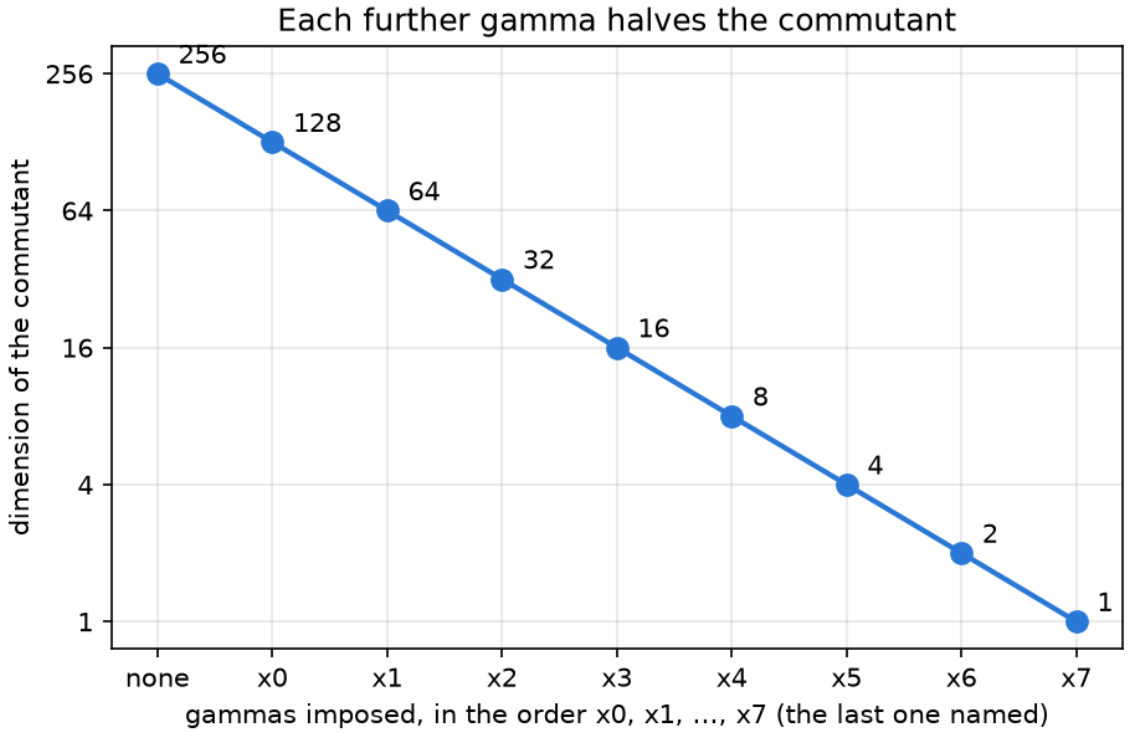

Figure 150: The dimension of the space of 16 by 16 matrices that commute with the gammas imposed so far (vertical axis, logarithmic with base 2), when the gammas are imposed one at a time in the order $x0$ to $x7$ (horizontal axis: the last gamma added). Without a condition all 256 entries are free; every further gamma halves the dimension, and with all eight only the multiples of the identity remain (dimension 1), computed exactly. (Notebook 05b, figure 3.)

## 11. The two halves: irreducible and inequivalent

Every $S^{ab}$ is $\mathrm{diag}(S_-^{ab}, S_+^{ab})$ with $8 \times 8$ blocks. The
next cell computes, exactly:

- the commutant of the 28 blocks $S_-^{ab}$ (64 unknowns): dimension 1 means the
  first half is irreducible; the same for the 28 blocks $S_+^{ab}$;
- the intertwiners $X$ with $X S_+^{ab} = S_-^{ab} X$ and with $X S_-^{ab} =
  S_+^{ab} X$ (with ‘commutation_system‘ the pairs are $(S_-, S_+)$ and $(S_+,
  S_-)$): dimension 0 means the only intertwiner is zero, so the halves are
  inequivalent;
- the **negative control**: the artificial $16 \times 16$ matrices
  $\mathrm{diag}(S_-^{ab}, S_-^{ab})$, two copies of the *same* half. Their
  commutant must have dimension 4 ($X = \begin{pmatrix} p 1_8 & q 1_8 \\ r 1_8 & s 1_8
  \end{pmatrix}$): this shows that the computation would detect equivalent halves.
```

## 13. What this notebook showed

- A matrix equation $LX = XR$ for an unknown matrix is a system of linear
  equations; its solutions form a space of dimension (number of unknowns) minus
  (rank), and the rank can be computed exactly.
- The 256 Clifford products of the author's gammas are independent: they span all
  $16 \times 16$ matrices; the 128 even ones are block diagonal and span all
  block-diagonal matrices ($64 + 64$).
- Only the multiples of 1 commute with all eight gammas: the 16 components carry
  an **irreducible** representation of Pin(4,4). The equation system has exactly
  one zero eigenvalue of $A^T A$, and all its eigenvalues are predicted exactly by
  the sign rule. Each further gamma halves the commutant: 256, 128, ..., 1.
- The matrices that commute with the 28 generators $S^{ab}$ are exactly
  $pP_- + qP_+$ (dimension 2): under Spin(4,4) the components split into the two
  chiral halves of 8.
- Each half is irreducible, and the two halves are **inequivalent** (no nonzero
  intertwiner); the negative control with two equal halves gives 4 instead of 2.
  The gammas exchange the halves, which is how the two inequivalent halves of
```

```
  Spin(4,4) form one irreducible representation of Pin(4,4).
- The ranks 256 and 128 and the dimensions 1, 2, 1, 1, 0 and 0 equal the numbers
  recorded in ‘Revision/algebra/reports/python-algebra.json‘ and
  ‘wolfram-algebra.json‘. The halving sequence 256, 128, ..., 1, the eigenvalue
  steps of $A^TA$ and the value 4 of the negative control are this notebook’s own
  computations.
```

5.17 Line-by-line walk-through of Notebook 05b

The notebook has 17 code cells. In [1] is the set-up cell, word for word the one of Notebook 05a explained in Section 5.10, except the line `NOTEBOOK_ID = "05b" # this notebook: chapter 05 , example b`; its comment lines repeat the instructions of Section 5.15. As in Section 5.10, the docstrings of the functions (the texts in triple quotes below a `def` line) are left out of the quotations, and a long caption given to `save_figure` is replaced by a line `...`); the full caption is printed under the figure in the complete text of the notebook.

In [2], the gammas and the recorded checks.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1
```

These lines load the modules and read the gammas exactly as In [2] and In [3] of Notebook 05a do (Section 5.10): `fixture` is the record, `COORDS` the coordinate names, `ETA` the signs η_{aa}, `gamma` the eight matrices of whole numbers and `I16` the identity.

```
REPORT_FILES = {"python": "Revision/algebra/reports/python-algebra.json",
                "wolfram": "Revision/algebra/reports/wolfram-algebra.json"}
VERDICTS = {}  # (report key, check name) -> (verdict in lower case, detail text)
for key, path in REPORT_FILES.items():
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in report_data["checks"]:
        VERDICTS[(key, entry["name"])] = (entry["verdict"].lower(), entry["detail"])

def recorded(key, name):
    return VERDICTS[(key, name)][0] == "pass"

def detail(key, name):
    return VERDICTS[(key, name)][1]
```

```
def record_of(key, name):
    return f"{REPORT_FILES[key]}, check {name}"

def check_reproduces(condition, name, record):
    collected = io.StringIO()
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together
```

The two reports are read and the helpers `recorded`, `record_of` and `check_reproduces` are defined as in Notebook 05a. The new helper `detail(key, name)` returns the detail text of a recorded check (`[1]`, the second element of the stored pair); several checks below compare a number with the number written in that text.

```
clifford_ok = all(
    np.array_equal(gamma[x] @ gamma[y] + gamma[y] @ gamma[x],
                   2 * ETA[x] * I16 if x == y else 0 * I16)
    for x in COORDS for y in COORDS)
check_reproduces(clifford_ok and recorded("python", "clifford_relation"),
                 "{gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs",
                 record=record_of("python", "clifford_relation"))
```

The Clifford relation is checked for the 64 pairs in one expression: `all(... for x in COORDS for y in COORDS)` runs through all pairs and is true when every comparison is; `0 * I16` is the zero matrix.

In [3], the tools.

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over QQ

def commutation_system(lefts, rights):
    blocks = []
    for L, R in zip(lefts, rights):
        n, m = L.shape[0], R.shape[0]
        blocks.append(np.kron(L, np.eye(m, dtype=np.int64))
                      - np.kron(np.eye(n, dtype=np.int64), R.T))
    return np.vstack(blocks)  # the blocks stacked on top of each other
```

`commutation_system` builds the coefficient matrix of Section 5.13 for a list of equations $LX - XR = 0$, one for each pair (L, R) of the two lists (`zip` pairs them). For each pair it reads the sizes n and m, forms $\mathrm{kron}(L, 1_m) - \mathrm{kron}(1_n, R^T)$ with numpy's Kronecker product `np.kron`, and `np.vstack` stacks all blocks on top of each other.

```
def exact_rank(A):
    return DomainMatrix.from_list(A.tolist(), sp.QQ).rank()
```

```
def solution_basis(A, n, m):
    null = DomainMatrix.from_list(A.tolist(), sp.QQ).nullspace().to_Matrix()
    return [np.array(null.row(k).tolist()[0], dtype=float).reshape(n, m)
            for k in range(null.rows)]
```

`DomainMatrix.from_list(..., sp.QQ)` makes an exact sympy matrix whose entries are rational numbers (`QQ` is sympy's name for the rational numbers). Its `.rank()` is computed by Gaussian elimination with fractions, without rounding. `.nullspace()` returns a basis of the solutions of $Ay = 0$, one solution per row; `.to_Matrix()` turns it into an ordinary sympy matrix. `solution_basis` takes each row (`null.row(k)`), turns it into a numpy array of floating-point numbers and reshapes the nm numbers into an $n \times m$ matrix (the unknowns were listed row by row, so `reshape` restores the matrix).

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed
X = rng.integers(-5, 6, size=(16, 16))  # a random 16 x 16 matrix, entries -5..5
L, R = gamma["x1"], gamma["x4"]
A = commutation_system([L], [R])
say(f"one pair (L, R) gives {A.shape[0]} equations for {A.shape[1]} unknowns")
check(np.array_equal(A @ X.reshape(256), (L @ X - X @ R).reshape(256)),
      "the coefficient matrix applied to X row by row gives L X - X R")
```

The construction is tested before it is used. `np.random.default_rng(12345)` is a random-number generator started with the fixed **seed** 12345, so that every run draws the same numbers; `rng.integers(-5, 6, size=(16, 16))` draws a 16×16 matrix of whole numbers from -5 to 5 (the upper end 6 is excluded). For $L = \gamma^{(x1)}$ and $R = \gamma^{(x4)}$ the coefficient matrix has 256 rows and 256 columns (printed). The check multiplies it with the 256 entries of X listed row by row (`X.reshape(256)`) and compares the result with the entries of $LX - XR$ listed in the same order.

In [4], the warm-up.

```
M = np.array([[0, 1], [1, 0]], dtype=np.int64)
A_small = commutation_system([M], [M])  # 4 equations for the 4 entries p, q, r, s
rank_small = exact_rank(A_small)
basis_small = solution_basis(A_small, 2, 2)
say(f"coefficient matrix (rows = equations, columns = p, q, r, s):")
for row in A_small.tolist():
    say(f"    {row}")
say(f"rank {rank_small}; dimension of the solution space {4 - rank_small}")
for k, b in enumerate(basis_small, 1):
    say(f"basis solution {k}: rows {b.astype(int).tolist()}")
check(rank_small == 2 and len(basis_small) == 2,
      "warm-up: the 2 x 2 matrices commuting with M form a space of dimension 2")
```

For $M = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $X = \begin{pmatrix} p & q \\ r & s \end{pmatrix}$ the equation $MX - XM = 0$ reads $r - q = 0$, $s - p = 0$, $p - s = 0$, $q - r = 0$, the four printed rows of coefficients (columns p, q, r, s). Two of them repeat the other two, so the rank is 2 and the solution space has dimension $4 - 2 = 2$. `enumerate(basis_`

`small, 1)` numbers the basis solutions from 1; `.astype(int)` turns them into whole numbers for printing. The two printed solutions are M itself and the identity, as the hand computation of the notebook's text predicts.

In [5], the 256 products of different gammas.

```
import itertools  # subsets of a given size
from math import comb  # comb(8, k): the number of subsets of size k

products = {}  # degree k -> list of the Clifford products of degree k
for k in range(9):
    products[k] = []
    for subset in itertools.combinations(COORDS, k):
        p = I16
        for x in subset:
            p = p @ gamma[x]
        products[k].append(p)
```

For each degree $k = 0, \ldots, 8$ the cell lists every subset of k directions in the order $x0, \ldots, x7$ and multiplies their gammas; for $k = 0$ the only subset is empty and the product is the identity. `products[k]` is the list of the $\binom{8}{k}$ products of degree k; `comb(8, k)` from the module `math` computes this binomial number.

```
rows_all = np.array([p.reshape(256) for k in range(9) for p in products[k]])
rows_even = np.array([p.reshape(256) for k in (0, 2, 4, 6, 8) for p in products[k]])
rank_all, rank_even = exact_rank(rows_all), exact_rank(rows_even)
cumulative = []  # the rank after adding the degrees 0, 1, ..., k
for k in range(9):
    cumulative.append(exact_rank(np.array(
        [p.reshape(256) for j in range(k + 1) for p in products[j]])))
```

Each product is written as one row of 256 numbers (`reshape(256)`), giving a 256×256 array for all products and a 128×256 array for the even ones; their exact ranks are computed. `cumulati ve[k]` is the rank of all products of degrees 0 to k.

```
for k in range(9):
    say(f"degree {k}: {len(products[k]):2d} products (comb(8, {k}) = {comb(8, k):2d});"
        f" rank of all products up to degree {k}: {cumulative[k]}")
say(f"rank of all 256 products: {rank_all}; rank of the 128 even products: "
    f"{rank_even}")
check_reproduces(rank_all == 256 and f"rank {rank_all} (Fraction elimination)"
                 in detail("python", "clifford_products_span_M16")
                 and recorded("python", "clifford_products_span_M16")
                 and recorded("wolfram", "Clifford_basis_spans_full_matrix_algebra"),
                 "the 256 Clifford products are independent: they span all 16 x 16 "
                 "matrices",
                 record=record_of("python", "clifford_products_span_M16"))
```

The nine printed lines show the numbers of products 1, 8, 28, 56, 70, 56, 28, 8, 1 and the cumulative ranks 1, 9, 37, 93, 163, 219, 247, 255, 256: each degree raises the rank by exactly the number of its

products, so no product is a combination of the others. (`{len(products[k]):2d}` writes a whole number in two places.) The check requires the rank 256 and that the recorded detail text contains the words `rank 256 (Fraction elimination)`: the record found the same number.

```
even_diagonal = all(not p[:8, 8:].any() and not p[8:, :8].any()
                    for k in (0, 2, 4, 6, 8) for p in products[k])
odd_off = all(not p[:8, :8].any() and not p[8:, 8:].any()
              for k in (1, 3, 5, 7) for p in products[k])
check_reproduces(rank_even == 128 and even_diagonal and odd_off
                 and f"rank {rank_even} (Fraction)"
                 in detail("python", "even_products_span_M8_plus_M8")
                 and recorded("python", "even_products_span_M8_plus_M8")
                 and recorded("wolfram", "even_subalgebra_dimension"),
                 "the 128 even products are block diagonal and independent (64 + 64); "
                 "the odd ones are block off-diagonal",
                 record=record_of("python", "even_products_span_M8_plus_M8"))
```

`p[:8, 8:]` is the top-right block (rows 1 to 8, columns 9 to 16) and `p[8:, :8]` the bottom-left block; `.any()` is true when some entry is not zero. So `even_diagonal` says that every even product has zero off-diagonal blocks, and `odd_off` that every odd product has zero diagonal blocks, the block rule of Section 5.5. The check adds the rank 128 and the recorded number.

In [6], the picture of the products and ranks.

```
from matplotlib.patches import Patch  # a coloured square for a legend

degrees = np.arange(9)
counts = [len(products[k]) for k in range(9)]
colors = ["#2a78d6" if k % 2 == 0 else "#eb6834" for k in range(9)]
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
axes[0].bar(degrees, counts, color=colors, edgecolor="white", linewidth=2)
for k in range(9):
    axes[0].text(k, counts[k] + 1.5, str(counts[k]), ha="center")
axes[0].set_xlabel("degree $k$ (number of different gammas multiplied)")
axes[0].set_ylabel("number of products")
axes[0].set_title(r"$\binom{8}{k}$ products of degree $k$")
axes[0].set_ylim(0, 80)
axes[0].legend(handles=[Patch(color="#2a78d6", label="even degree"),
                        Patch(color="#eb6834", label="odd degree")],
               loc="upper right")
```

`np.arange(9)` is the array $0, 1, \ldots, 8$. `k % 2` is the remainder of k divided by 2, so even degrees get blue and odd degrees orange. `axes[0].bar` draws one bar per degree with the height of its count, and `text` writes the count just above each bar. A `Patch` is a coloured square for a legend that is made by hand (the bars themselves carry no labels).

```
added = np.cumsum(counts)  # how many products have been added up to degree k
axes[1].plot(added, cumulative, "o-", color="#2a78d6", linewidth=2, markersize=8,
             label="exact rank")
axes[1].plot([0, 256], [0, 256], ":", color="black", linewidth=1,
```

```
             label="rank = number of products")
axes[1].set_xlabel("number of products added (degrees 0 to $k$)")
axes[1].set_ylabel("rank")
axes[1].set_title("The rank grows by one for every product")
axes[1].legend(loc="upper left")
save_figure(fig, "clifford_products",
            ...)
```

`np.cumsum` adds up the counts: 1, 9, 37, 93, 163, 219, 247, 255, 256 products after the degrees 0 to k. The right picture plots the cumulative ranks against these numbers (`"o-"` draws dots joined by lines) and the dotted line rank = number of products. In `05b_1_clifford_products.png` the dots lie exactly on the dotted line.

In [7], the commutant of the eight gammas.

```
gammas = [gamma[x] for x in COORDS]
A_pin = commutation_system(gammas, gammas)  # 8 x 256 = 2048 equations
rank_pin = exact_rank(A_pin)
basis_pin = solution_basis(A_pin, 16, 16)
dimension_pin = 256 - rank_pin
say(f"equations {A_pin.shape[0]}, unknowns {A_pin.shape[1]}, rank {rank_pin}, "
    f"dimension of the commutant {dimension_pin}")
```

With $L = R = \gamma^a$ the equations $\gamma^a X - X\gamma^a = 0$ say that X commutes with γ^a; for the eight gammas they are 2048 equations for 256 unknowns. The printed line shows the rank 255 and the dimension $256 - 255 = 1$.

```
only = basis_pin[0]
proportional = np.array_equal(only / only[0, 0], np.eye(16))  # a multiple of 1?
say(f"the basis solution divided by its entry (1,1) equals the identity: "
    f"{proportional}")
check_reproduces(dimension_pin == 1 and len(basis_pin) == 1 and proportional
                 and f"= {dimension_pin} (Fraction)"
                 in detail("python", "pin_commutant_dimension_1")
                 and recorded("python", "pin_commutant_dimension_1")
                 and recorded("wolfram", "Pin44_irreducible_commutant_dim_1"),
                 "only the multiples of 1 commute with all eight gammas: Pin(4,4) acts "
                 "irreducibly on the 16 components",
                 record=record_of("python", "pin_commutant_dimension_1"))
```

The only basis solution is divided by its entry in row 1, column 1 (`only[0, 0]`), and the result is compared with the identity: True. The check is Theorem P, with the recorded dimension.

In [8], the second engine.

```
N_pin = A_pin.T @ A_pin  # 256 x 256, whole numbers, symmetric
eigen_pin = np.linalg.eigvalsh(N_pin.astype(float))  # sorted from small to large
zeros_pin = int(np.sum(np.abs(eigen_pin) < 1e-9))
say(f"numpy: eigenvalues of A^T A below 1e-9: {zeros_pin}")
```

$N = A^T A$ is computed in whole numbers, its 256 eigenvalues in floating-point numbers, and the eigenvalues below 10^{-9} in size are counted: exactly one, the dimension of the commutant again.

```
predicted = []  # the eigenvalue 4 n(P) of every Clifford product P
exact_eigenvectors = True
for k in range(9):
    n_anti = k if k % 2 == 0 else 8 - k  # gammas anticommuting with a product
    for p in products[k]:
        predicted.append(4 * n_anti)
        exact_eigenvectors &= np.array_equal(N_pin @ p.reshape(256),
                                             4 * n_anti * p.reshape(256))
```

The notebook's text explains why every product P of different gammas, written as a row of 256 numbers, is an eigenvector of N with the eigenvalue $4n(P)$, where $n(P)$ is the number of gammas that anticommute with P. By Rule 1 of Section 5.3, a product of even degree k anticommutes with its k factors and commutes with the others, so $n = k$; a product of odd degree anticommutes with the $8 - k$ gammas that are not factors, so $n = 8 - k$. The loop collects the predicted eigenvalue of each product and checks the eigenvector equation exactly (`&=` keeps `exact_eigenvectors` true only while every test passes).

```
predicted = np.sort(np.array(predicted))
values, multiplicities = np.unique(predicted, return_counts=True)
say("predicted eigenvalues of A^T A, written value x multiplicity:")
say("    " + ", ".join(f"{v} x {c}" for v, c in zip(values, multiplicities)))
check(exact_eigenvectors and zeros_pin == 1
      and np.max(np.abs(eigen_pin - predicted)) < 1e-9,
      "A^T A has exactly one zero eigenvalue; every Clifford product P is an "
      "eigenvector with eigenvalue 4 n(P)")
```

The 256 predicted eigenvalues are sorted; `np.unique(..., return_counts=True)` lists each different value once together with how often it occurs. The printed line reads 0 x 1, 4 x 8, 8 x 28, ..., 32 x 1: the value $4n$ occurs as often as there are products with that n. The check requires the exact eigenvector equations, one zero eigenvalue, and that numpy's sorted eigenvalues agree with the sorted predictions to within 10^{-9}. The 256 products are independent, so they are all the eigenvectors, and the prediction is the complete list.

In [9], imposing the gammas one at a time.

```
halving = [256]  # dimension of the commutant of the first j gammas, j = 0, 1, ..., 8
for j in range(1, 9):
    A_j = commutation_system(gammas[:j], gammas[:j])
    halving.append(256 - exact_rank(A_j))
for j in range(9):
    names = ", ".join(COORDS[:j]) if j else "none"
    say(f"gammas imposed: {j} ({names}); commutant dimension {halving[j]}")
check(halving == [256 // 2 ** j for j in range(9)],
      "every further gamma halves the commutant: 256, 128, 64, ..., 2, 1")
```

`gammas[:j]` is the list of the first j gammas. For $j = 1, \ldots, 8$ the exact dimension of their commutant is appended to `halving`, which starts with 256 (no condition). The printed lines show 256, 128,

64, 32, 16, 8, 4, 2, 1, and the check compares the list with $256/2^j$ (`2 ** j` is 2^j; `//` divides whole numbers).

In [10], the 28 generators.

```
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 pairs
S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4 for a, b in pairs}
entries = sorted({float(v) for s in S.values() for v in s.flat})
say(f"{len(S)} generators S^ab; their entries are {entries}")
```

`enumerate(COORDS)` gives each name with its position `i`; `COORDS[i + 1:]` is the list of the names after it, so `pairs` lists the 28 planes (a, b) with a before b. `S` stores $\frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$ for each plane; the division by 4 makes floating-point numbers, but halves are stored exactly. The printed line shows 28 generators with the entries -0.5, 0, 0.5.

```
check_reproduces(len(S) == 28 and entries == [-0.5, 0.0, 0.5]
                 and all(np.array_equal(S[(a, b)], gamma[a] @ gamma[b] / 2)
                         for a, b in pairs)
                 and recorded("python", "S_definition"),
                 "S^ab = (1/4)[gamma^a, gamma^b] = (1/2) gamma^a gamma^b: 28 matrices "
                 "with entries 0, +1/2, -1/2",
                 record=record_of("python", "S_definition"))
check_reproduces(all(not s[:8, 8:].any() and not s[8:, :8].any() for s in S.values())
                 and recorded("python", "S_block_diagonal"),
                 "every S^ab is block diagonal: it maps each chiral half into itself",
                 record=record_of("python", "S_block_diagonal"))
```

The first check confirms $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$ and the entries; the second that every generator is block diagonal (it is even).

In [11], the commutant of the generators.

```
generators = [(gamma[a] @ gamma[b]).astype(np.int64) for a, b in pairs]  # 2 S^ab
A_spin = commutation_system(generators, generators)  # 7168 equations
rank_spin = exact_rank(A_spin)
basis_spin = solution_basis(A_spin, 16, 16)
dimension_spin = 256 - rank_spin
```

For the exact computation the cell uses the whole-number matrices $2S^{ab} = \gamma^a\gamma^b$, which have the same commutant as the S^{ab} (a matrix commutes with S exactly when it commutes with $2S$). The $28 \times 256 = 7168$ equations have the exact rank 254 and a solution space of dimension 2.

```
P_minus = np.diag([1] * 8 + [0] * 8)  # diag(1_8, 0): components 1 to 8
P_plus = np.diag([0] * 8 + [1] * 8)  # diag(0, 1_8): components 9 to 16
together = np.array([b.reshape(256) for b in basis_spin]
                    + [P_minus.reshape(256), P_plus.reshape(256)])
same_span = np.linalg.matrix_rank(together) == 2  # four matrices, two directions
eigen_spin = np.linalg.eigvalsh((A_spin.T @ A_spin).astype(float))
zeros_spin = int(np.sum(np.abs(eigen_spin) < 1e-9))
```

`np.diag(list)` makes the diagonal matrix with the listed diagonal: the two projectors. The two basis solutions and the two projectors, written as rows, form four rows; if their rank is 2, the two pairs span the same space (`np.linalg.matrix_rank` computes a floating-point rank, which is reliable for such small whole numbers). The second engine counts the zero eigenvalues of $A^T A$.

```
say(f"equations {A_spin.shape[0]}, rank {rank_spin}, dimension {dimension_spin}; "
    f"numpy: zero eigenvalues of A^T A: {zeros_spin}")
say(f"the basis and P_-, P_+ span the same space: {same_span}")
check_reproduces(dimension_spin == 2 and zeros_spin == 2 and same_span
                 and f"= {dimension_spin} (Fraction)"
                 in detail("python", "spin_commutant_dimension_2")
                 and recorded("python", "spin_commutant_dimension_2")
                 and recorded("wolfram", "Spin44_commutant_dim_2_chiral_projectors"),
                 "the commutant of the 28 S^ab has dimension 2, spanned by P_- and P_+",
                 record=record_of("python", "spin_commutant_dimension_2"))
```

The printed lines report 7168 equations, rank 254, dimension 2, two zero eigenvalues and True. The check confirms the recorded dimension 2.

In [12], the picture of the eigenvalues of $A^T A$.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
for ax, eig, zeros, title in [
        (axes[0], eigen_pin, zeros_pin, "eight gammas (Pin(4,4))"),
        (axes[1], eigen_spin, zeros_spin, "28 generators $S^{ab}$ (Spin(4,4))")]:
    index = np.arange(1, 257)  # the eigenvalues numbered 1 to 256
    ax.plot(index, eig, color="#2a78d6", linewidth=2, label="eigenvalue")
    ax.plot(index[:zeros], eig[:zeros], "o", color="#eb6834", markersize=9,
            label=f"zero eigenvalues: {zeros}")
    ax.set_xlabel("number of the eigenvalue (sorted)")
    ax.set_title(f"$A^T A$ for the {title}")
    ax.legend(loc="lower right")
axes[0].set_ylabel("eigenvalue of $A^T A$")
save_figure(fig, "system_eigenvalues",
            ...)
```

The loop draws the same kind of picture for the two systems: the sorted eigenvalues against their numbers 1 to 256 (`np.arange(1, 257)`), and orange dots on the first `zeros` of them, the zero eigenvalues. In `05b_2_system_eigenvalues.png` the left curve climbs in the steps 0, 4, 8, ..., 32 with one dot at 0; the right curve has two dots at 0.

In [13], the picture of the halving.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
ax.plot(range(9), halving, "o-", color="#2a78d6", linewidth=2, markersize=8)
for j in range(9):
    ax.annotate(str(halving[j]), (j, halving[j]), textcoords="offset points",
                xytext=(8, 4))
ax.set_yscale("log", base=2)
ax.set_yticks([1, 4, 16, 64, 256], ["1", "4", "16", "64", "256"])
ax.set_xticks(range(9), ["none"] + COORDS)
```

```
ax.set_xlabel("gammas imposed, in the order x0, x1, ..., x7 (the last one named)")
ax.set_ylabel("dimension of the commutant")
ax.set_title("Each further gamma halves the commutant")
save_figure(fig, "commutant_halving",
            ...)
```

The nine dimensions are drawn against the number of gammas imposed; `annotate` writes each value next to its dot, shifted by 8 and 4 points. `set_yscale("log", base=2)` makes the vertical axis logarithmic with base 2, so that each halving is a step of the same size and the dots lie on a straight line. In `05b_3_commutant_halving.png` the line descends evenly from 256 to 1.

In [14], the picture of the Spin(4,4) commutant.

```
from matplotlib.colors import LinearSegmentedColormap

# What the caption below says about the two basis matrices, checked: each is
# diagonal, has no negative entry, and is constant on each half (rows 1-8, 9-16).
shapes_ok = all(np.array_equal(b, np.diag(np.diag(b))) and b.min() >= 0
                and len(set(np.diag(b)[:8].tolist())) == 1
                and len(set(np.diag(b)[8:].tolist())) == 1 for b in basis_spin)
check(shapes_ok, "the two basis matrices are diagonal, nonnegative and constant on "
      "each half")
```

Before drawing, the cell checks what the caption says. `np.diag(b)` of a matrix is its diagonal, and `np.diag` of that list is the diagonal matrix with it; equality means that `b` is diagonal. `b.min() >= 0` says no entry is negative. `set(...)` of the first eight diagonal entries has one element exactly when they are all equal; the same for the last eight.

```
SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
pictures = [(basis_spin[0], "sympy basis matrix 1"),
            (basis_spin[1], "sympy basis matrix 2"),
            (P_minus, "$P_- = \\mathrm{diag}(1_8, 0)$"),
            (P_plus, "$P_+ = \\mathrm{diag}(0, 1_8)$")]
fig, axes = plt.subplots(1, 4, figsize=(13.0, 3.9))
for k, (ax, (matrix, title)) in enumerate(zip(axes, pictures)):
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.axhline(7.5, color="black", linewidth=0.8)
    ax.axvline(7.5, color="black", linewidth=0.8)
    ax.set_xlabel("column")
    if k == 0:
        ax.set_ylabel("row")
    ax.grid(False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "spin_commutant",
            ...)
```

The colour map of Notebook 05a is made again. `pictures` pairs the four matrices with their titles; in an ordinary string a backslash must be doubled, so `"\\mathrm"` gives `\mathrm`. The loop draws

each as a heat map with the half lines (`enumerate` gives the number `k` of each picture, so that only the first gets the word row). `05b_4_spin_commutant.png` shows four diagonal matrices, each grey or red, constant on each half.

In [15], the two halves.

```
minus_blocks = [g[:8, :8] for g in generators]  # the blocks of 2 S^ab on half -
plus_blocks = [g[8:, 8:] for g in generators]  # the blocks of 2 S^ab on half +
dim_minus = 64 - exact_rank(commutation_system(minus_blocks, minus_blocks))
dim_plus = 64 - exact_rank(commutation_system(plus_blocks, plus_blocks))
dim_minus_plus = 64 - exact_rank(commutation_system(minus_blocks, plus_blocks))
dim_plus_minus = 64 - exact_rank(commutation_system(plus_blocks, minus_blocks))
```

`minus_blocks` are the top-left 8×8 blocks of the 28 matrices $2S^{ab}$, `plus_blocks` the bottom-right ones. Each system has 28×64 equations for the 64 entries of an 8×8 unknown X. With the pairs $(L, R) = (S_-, S_-)$ the solutions are the commutant on the first half; with (S_+, S_+) on the second; with (S_-, S_+) they are the X with $S_- X = X S_+$, the intertwiners from the second half to the first; with (S_+, S_-) those in the other direction.

```
Z8 = np.zeros((8, 8), dtype=np.int64)
doubled = [np.block([[m, Z8], [Z8, m]]) for m in minus_blocks]  # the control
dim_control = 256 - exact_rank(commutation_system(doubled, doubled))
say(f"commutant on half -: {dim_minus}; on half +: {dim_plus}")
say(f"intertwiners: {dim_minus_plus} and {dim_plus_minus}")
say(f"control (two copies of half -): commutant dimension {dim_control}")
```

The negative control builds artificial 16×16 matrices $\mathrm{diag}(S_-, S_-)$ with the same block twice and computes their commutant. The printed lines show the dimensions 1 and 1, the intertwiners 0 and 0, and 4 for the control.

```
check_reproduces(dim_minus == 1 and dim_plus == 1
                 and "dimension 1 (sympy 1)"
                 in detail("python", "spin_halves_irreducible")
                 and recorded("python", "spin_halves_irreducible")
                 and recorded("wolfram", "chiral_halves_irreducible"),
                 "each chiral half is an irreducible representation of Spin(4,4)",
                 record=record_of("python", "spin_halves_irreducible"))
check_reproduces(dim_minus_plus == 0 and dim_plus_minus == 0
                 and "dimension 0 (sympy 0)"
                 in detail("python", "spin_halves_inequivalent")
                 and recorded("python", "spin_halves_inequivalent")
                 and recorded("wolfram", "chiral_halves_inequivalent_intertwiners_0"),
                 "the two halves are inequivalent: the only intertwiner is zero",
                 record=record_of("python", "spin_halves_inequivalent"))
check(dim_control == 4,
      "negative control: two copies of the same half give commutant dimension 4")
```

The three checks state Theorem S in the form of the record (irreducible halves, no intertwiner) and the control value 4 of Lemma 4.

In [16], why Pin(4,4) sees one block, and the dimensions.

```
check_reproduces(all(np.array_equal(gamma[x] @ P_minus, P_plus @ gamma[x])
                     for x in COORDS)
                 and recorded("python", "reflections_exchange_halves"),
                 "gamma^a P_- = P_+ gamma^a: every reflection exchanges the two halves",
                 record=record_of("python", "reflections_exchange_halves"))
```

The check repeats the fact of Section 5.5 that every gamma exchanges the halves.

```
labels = ["Pin(4,4) on all 16", "Spin(4,4) on all 16", "Spin(4,4) on half -",
          "Spin(4,4) on half +", "intertwiners - to +", "intertwiners + to -",
          "control: two equal halves"]
values = [dimension_pin, dimension_spin, dim_minus, dim_plus, dim_minus_plus,
          dim_plus_minus, dim_control]
colors = ["#2a78d6"] * 6 + ["#eb6834"]  # blue: the theory, orange: the control
fig, ax = plt.subplots(figsize=(8.0, 4.4))
positions = np.arange(len(labels))[::-1]  # the first label at the top
ax.barh(positions, values, color=colors, edgecolor="white", linewidth=2)
for y, v in zip(positions, values):
    ax.text(v + 0.06, y, str(v), va="center")
ax.set_yticks(positions, labels)
ax.set_xlim(0, 4.6)
ax.set_xlabel("dimension of the space of solutions")
ax.set_title("Commutants and intertwiners")
legend_squares = [Patch(color="#2a78d6", label="the author's spinor (computed)"),
                  Patch(color="#eb6834", label="negative control (artificial)")]
ax.legend(handles=legend_squares, loc="upper right")
save_figure(fig, "dimensions",
            ...)
```

The seven computed dimensions are drawn as horizontal bars (`barh`), six blue and the control orange. `[::-1]` reverses the array of positions, so that the first label stands at the top; each value is written just right of its bar. `05b_5_dimensions.png` shows the bars 1, 2, 1, 1, 0, 0 and the orange bar 4.

In [17], the last check.

```
FIGURES = ["05b_1_clifford_products.png", "05b_2_system_eigenvalues.png",
           "05b_3_commutant_halving.png", "05b_4_spin_commutant.png",
           "05b_5_dimensions.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the five figure files of notebook 05b exist")
all_checks_passed()
```

The five figure files must exist, and the last line reads ALL 17 CHECKS PASSED (notebook 05b): one check each in In [2], In [3], In [4], In [7], In [8], In [9], In [11], In [14], In [16] and In [17], two each in In [5] and In [10], and three in In [15]. Ten of them reproduce recorded checks; the other seven (in In [3], In [4], In [8], In [9], In [14], the control in In [15], and In [17]) are the notebook's own computations.

5.18 Spin transformations: rotations, boosts and the double cover

A **spin transformation** is a 16×16 matrix R that acts on the components, $\Psi \to R\Psi$, and at the same time turns the eight directions into each other. This section builds them from the generators and proves how they act.

The commutation rules of so(4,4). The **commutator** of two matrices is $[M, N] = MN - NM$. For commutators the **product rule** $[A, BC] = [A, B]C + B[A, C]$ holds, because both sides are $ABC - BCA$ (on the right, $ABC - BAC + BAC - BCA$). For $c \neq d$, $S^{cd} = \frac{1}{2}\gamma^c\gamma^d$, and the product rule with the vector rule of Section 5.12 gives

$$[S^{ab}, \gamma^c\gamma^d] = (\eta^{bc}\gamma^a - \eta^{ac}\gamma^b)\gamma^d + \gamma^c(\eta^{bd}\gamma^a - \eta^{ad}\gamma^b).$$

Each product of two gammas is $\gamma^x\gamma^y = \frac{1}{2}[\gamma^x, \gamma^y] + \frac{1}{2}\{\gamma^x, \gamma^y\} = 2S^{xy} + \eta^{xy}1$ (the Clifford relation for the second part). Inserting this, the four number terms $\eta^{bc}\eta^{ad} - \eta^{ac}\eta^{bd} + \eta^{bd}\eta^{ca} - \eta^{ad}\eta^{cb}$ cancel in pairs, and with $S^{ca} = -S^{ac}$, $S^{cb} = -S^{bc}$ and a division by 2:

$$[S^{ab}, S^{cd}] = \eta^{bc}S^{ad} - \eta^{ac}S^{bd} - \eta^{bd}S^{ac} + \eta^{ad}S^{bc}.$$

These are the commutation rules of the **Lie algebra so(4,4)**, the algebra of infinitesimal turnings of the 4+4 directions. The Revision record checks them for all $28 \times 28 = 784$ pairs of generators.

The exponential of a matrix. For a square matrix M the **exponential** is the power series

$$\exp(M) = 1 + M + \tfrac{1}{2}M^2 + \tfrac{1}{6}M^3 + \cdots = \sum_{k \geq 0} \frac{M^k}{k!},$$

the same series as for e^x; it converges for every square matrix (a fact of analysis, quoted here without proof). Fix a plane (a, b) with $a \neq b$ and put $J = \gamma^a\gamma^b = 2S^{ab}$, so that $\theta S^{ab} = \frac{\theta}{2}J$. Then

$$JJ = \gamma^a\gamma^b\gamma^a\gamma^b = -\gamma^a\gamma^a\gamma^b\gamma^b = -\eta_{aa}\eta_{bb}\,1,$$

where the second step exchanges the two middle factors (they anticommute) and the third is the Clifford relation twice.

- **Rotation** ($\eta_{aa}\eta_{bb} = +1$): $JJ = -1$, so $J^{2n} = (-1)^n$ and $J^{2n+1} = (-1)^n J$. Splitting the series into even and odd powers and using the power series of cosine and sine, $\exp(\frac{\theta}{2}J) = \cos\frac{\theta}{2}\,1 + \sin\frac{\theta}{2}\,J$.
- **Boost** ($\eta_{aa}\eta_{bb} = -1$): $JJ = +1$, every power has the sign $+$, and the series of $\cosh x = \frac{1}{2}(e^x + e^{-x})$ and $\sinh x = \frac{1}{2}(e^x - e^{-x})$ give $\exp(\frac{\theta}{2}J) = \cosh\frac{\theta}{2}\,1 + \sinh\frac{\theta}{2}\,J$.

In both cases the inverse is $\exp(-\theta S^{ab})$: $(c1 + sJ)(c1 - sJ) = c^2 - s^2JJ$, which is $\cos^2 + \sin^2 = 1$ for a rotation and $\cosh^2 - \sinh^2 = 1$ for a boost (from the definitions, $\cosh^2 x - \sinh^2 x = \frac{1}{4}[(e^{2x} + 2 + e^{-2x}) - (e^{2x} - 2 + e^{-2x})] = 1$). The number θ is called the **angle** of a rotation and the **rapidity** of a boost.

How a rotation moves the directions: the half angle. Take the rotation in the plane $(x1, x2)$: $R = c1 + sJ$ with $J = \gamma^{(x1)}\gamma^{(x2)}$, $c = \cos\frac{\theta}{2}$, $s = \sin\frac{\theta}{2}$. By Rule 1, J anticommutes with $\gamma^{(x1)}$ and $\gamma^{(x2)}$ (a factor of a product of two: sign $(-1)^1$) and commutes with the other six gammas. Line by line:

$$R\gamma^{(x1)} = \gamma^{(x1)}(c1 - sJ) = \gamma^{(x1)}R^{-1}, \qquad \text{so} \qquad R\gamma^{(x1)}R^{-1} = \gamma^{(x1)}(c1 - sJ)^2.$$

The first step moves $\gamma^{(x1)}$ to the left through J (a sign); the second multiplies from the right by $R^{-1} = c1 - sJ$. Now

$$(c1 - sJ)^2 = c^2 - 2csJ + s^2JJ = (c^2 - s^2)1 - 2cs\,J = \cos\theta\,1 - \sin\theta\,J,$$

by $JJ = -1$ and the double-angle formulas $\cos^2\frac{\theta}{2} - \sin^2\frac{\theta}{2} = \cos\theta$ and $2\sin\frac{\theta}{2}\cos\frac{\theta}{2} = \sin\theta$. With $\gamma^{(x1)}J = \gamma^{(x1)}\gamma^{(x1)}\gamma^{(x2)} = \gamma^{(x2)}$:

$$R\gamma^{(x1)}R^{-1} = \cos\theta\,\gamma^{(x1)} - \sin\theta\,\gamma^{(x2)}.$$

In the same way $R\gamma^{(x2)}R^{-1} = \gamma^{(x2)}(\cos\theta\,1 - \sin\theta\,J) = \cos\theta\,\gamma^{(x2)} + \sin\theta\,\gamma^{(x1)}$ (because $\gamma^{(x2)}\gamma^{(x1)}\gamma^{(x2)} = -\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x2)} = -\gamma^{(x1)}$), and $R\gamma^cR^{-1} = \gamma^c$ for the other six directions. So conjugation by R turns the directions $x1$ and $x2$ by the **full** angle θ, while R itself contains only the **half** angle $\theta/2$. At $\theta = 2\pi$ the directions are back where they started, but

$$R(2\pi) = \cos\pi\,1 + \sin\pi\,J = -1.$$

A turn by 2π multiplies every spinor by -1; only a turn by 4π gives $R = +1$. This is the defining property of spinors.

How a boost moves the directions. For the boost in the plane $(x1, x4)$, $J = \gamma^{(x1)}\gamma^{(x4)}$ with $JJ = +1$, $c = \cosh\frac{\theta}{2}$ and $s = \sinh\frac{\theta}{2}$. The same steps give $R\gamma^{(x1)}R^{-1} = \gamma^{(x1)}(c1 - sJ)^2$ with $(c1 - sJ)^2 = (c^2 + s^2)1 - 2cs\,J = \cosh\theta\,1 - \sinh\theta\,J$; here $\cosh^2 x + \sinh^2 x = \cosh 2x$ and $2\sinh x\cosh x = \sinh 2x$ follow from the definitions by multiplying out, as above. Hence

$$R\gamma^{(x1)}R^{-1} = \cosh\theta\,\gamma^{(x1)} - \sinh\theta\,\gamma^{(x4)}, \qquad R\gamma^{(x4)}R^{-1} = \cosh\theta\,\gamma^{(x4)} - \sinh\theta\,\gamma^{(x1)}.$$

The pair of directions $(x1, x4)$ is mixed by a hyperbolic turn, which keeps $v_1^2 - v_4^2$ because $\cosh^2\theta - \sinh^2\theta = 1$, and never comes back.

Reading off the vector matrix with traces. For an even R write $R\gamma^cR^{-1} = \sum_d \Lambda_{dc}\gamma^d$ (Section 5.12). Since $\mathrm{tr}(\gamma^d\gamma^e) = 16\,\eta^{de}$ (for $d \neq e$ by Rule 5 with $k = 2$; for $d = e$ it is the trace of $\eta_{dd}1$), multiplying by γ^d and taking the trace leaves one term:

$$\Lambda_{dc} = \eta_{dd}\,\mathrm{tr}\big(\gamma^dR\gamma^cR^{-1}\big)/16.$$

Notebook 05d computes vector matrices this way.

The double cover. Since $\Lambda(-g) = \Lambda(g)$ (the two signs cancel in $g\gamma^c g^{-1}$), every vector matrix belongs to at least two spinor matrices, g and $-g$. There are no others. Proof: if $\Lambda(g) = \Lambda(h)$, then $k = gh^{-1}$ has $\Lambda(k) = \Lambda(g)\Lambda(h)^{-1} = 1$, that is $\alpha(k)\gamma^c k^{-1} = \gamma^c$ for every c. If k is even, $k\gamma^c = \gamma^c k$: k commutes with every gamma, so $k = \lambda 1$ by Theorem P of Section 5.13; and by the spinor norm below, $k^T C k = \pm C$, so $\lambda^2 = \pm 1$, and since k is a real matrix, $\lambda = \pm 1$. If k were odd, $k\gamma^c = -\gamma^c k$ for every c; then Γk commutes with every gamma (moving γ^c through Γk costs two signs), so $\Gamma k = \lambda 1$ and $k = \lambda\Gamma$, an even matrix, which is impossible for an odd element (Section 5.12). So $h = \pm g$. Status: PROVED. That every matrix of O(4,4) is the vector matrix of some element of Pin(4,4) is the theorem of Cartan and Dieudonné (every such matrix is a product of reflections), which this book quotes without proof (ASSUMED). With it, Pin(4,4) is a **double cover** of O(4,4) and Spin(4,4) of SO(4,4).

The forms that are kept. Two bilinears matter: $\Psi^\dagger C\Psi$ (the scalar) and $\Psi^\dagger B\Psi$ (the charge density).

First, for every generator, $(S^{ab})^T C + CS^{ab} = 0$. Proof for $a \neq b$: by Rule 4, $(S^{ab})^T = \frac{1}{2}\eta_{aa}\eta_{bb}\gamma^b\gamma^a = -\frac{1}{2}\eta_{aa}\eta_{bb}\gamma^a\gamma^b$, and by (C1) used twice, $\gamma^a\gamma^b C = \eta_{aa}\eta_{bb}C\gamma^a\gamma^b$. So $(S^{ab})^T C = -\frac{1}{2}(\eta_{aa}\eta_{bb})^2 C\gamma^a\gamma^b = -CS^{ab}$. For $R = \exp(\theta S^{ab})$ the transpose is $\exp(\theta(S^{ab})^T)$ (transpose every power), and $(S^T)^k C = C(-S)^k$ (move C to the left one factor at a time), so

$$R^T C = C\exp(-\theta S^{ab}) = CR^{-1}, \qquad R^T C R = C.$$

Products of exponentials keep it too: if $R_1^T C R_1 = C$ and $R_2^T C R_2 = C$, then $(R_1R_2)^T C(R_1R_2) = R_2^T(R_1^T C R_1)R_2 = C$. Since R is real, $(R\Psi)^\dagger C(R\Psi) = \Psi^\dagger R^T C R\Psi = \Psi^\dagger C\Psi$: **the scalar S is invariant** under every product of exponentials.

Second, $B = -iC\gamma^{(x4)}$. For a generator that does not involve $x4$ ($a, b \neq x4$), $(S^{ab})^\dagger B + BS^{ab} = 0$; for the seven generators $S^{(x4)b}$, $(S^{(x4)b})^\dagger B + BS^{(x4)b} = iC\gamma^b \neq 0$.

Proof of the first statement, line by line. Let $a \neq b$, both different from $x4$, and $S = S^{ab} = \frac{1}{2}\gamma^a\gamma^b$. S is real, so $S^\dagger = S^T$. First, by Rule 4 with $k = 2$,

$$S^T = \tfrac{1}{2}(-1)^1\eta_{aa}\eta_{bb}\,\gamma^a\gamma^b = -\tfrac{1}{2}\eta_{aa}\eta_{bb}\,\gamma^a\gamma^b.$$

Second, multiply by $B = -iC\gamma^{(x4)}$ from the right; the two minus signs give a plus:

$$S^T B = \tfrac{i}{2}\,\eta_{aa}\eta_{bb}\,\gamma^a\gamma^b C\gamma^{(x4)}.$$

Third, move C to the front with (C1) in the form $\gamma^c C = -\eta_{cc}C\gamma^c$, first past γ^b, then past γ^a:

$$\gamma^a\gamma^b C = \gamma^a(-\eta_{bb}C\gamma^b) = -\eta_{bb}(\gamma^a C)\gamma^b = -\eta_{bb}(-\eta_{aa}C\gamma^a)\gamma^b = \eta_{aa}\eta_{bb}\,C\gamma^a\gamma^b,$$

so that, with $(\eta_{aa}\eta_{bb})^2 = 1$,

$$S^T B = \tfrac{i}{2}\,(\eta_{aa}\eta_{bb})^2\,C\gamma^a\gamma^b\gamma^{(x4)} = \tfrac{i}{2}\,C\gamma^a\gamma^b\gamma^{(x4)}.$$

Fourth, $\gamma^{(x4)}$ commutes with the pair $\gamma^a\gamma^b$: by Rule 1 it passes two factors that are both different from $x4$, which costs $(-1)^2 = +1$. So $\gamma^a\gamma^b\gamma^{(x4)} = \gamma^{(x4)}\gamma^a\gamma^b$ and

$$S^T B = \tfrac{i}{2}\, C\gamma^{(x4)}\gamma^a\gamma^b.$$

Fifth, directly from the definitions,

$$BS = -iC\gamma^{(x4)}\,\tfrac{1}{2}\gamma^a\gamma^b = -\tfrac{i}{2}\, C\gamma^{(x4)}\gamma^a\gamma^b.$$

The sum of the last two lines is zero: $S^\dagger B + BS = 0$.

Proof of the second statement: with $S = \frac{1}{2}\gamma^{(x4)}\gamma^b$ (S is real, so $S^\dagger = S^T$),

$$BS = -\tfrac{i}{2}C\gamma^{(x4)}\gamma^{(x4)}\gamma^b = \tfrac{i}{2}C\gamma^b, \qquad S^T B = -\tfrac{i}{2}\eta_{bb}\gamma^{(x4)}\gamma^b C\gamma^{(x4)} = \tfrac{i}{2}C\gamma^{(x4)}\gamma^b\gamma^{(x4)} = \tfrac{i}{2}C\gamma^b,$$

where the first uses $\gamma^{(x4)}\gamma^{(x4)} = -1$; the second uses Rule 4 for S^T, then (C1) to move C to the front (sign $-\eta_{bb}$ for γ^b, $+1$ for $\gamma^{(x4)}$), then $\gamma^b\gamma^{(x4)} = -\gamma^{(x4)}\gamma^b$ and $\gamma^{(x4)}\gamma^{(x4)} = -1$. The sum is $iC\gamma^b$. So the charge density $\Psi^\dagger B\Psi$ is kept only by the transformations that leave the time $x4$ alone. This is what one expects: the charge density is the time component of the current J^a, and a boost that mixes the time $x4$ with another direction mixes it with the other components, as the charge density of special relativity does.

The spinor norm. For $g = \gamma(u_1)\cdots\gamma(u_k)$ in Pin(4,4) put $N(g) = \eta(u_1,u_1)\cdots\eta(u_k,u_k) = \pm 1$. Then

$$g^T C g = (-1)^k\, N(g)\, C.$$

Proof: from (C5), $(\gamma^a)^T = -C\gamma^a C$, so $(\gamma^a)^T C = -C\gamma^a$ and, by linearity, $\gamma(u)^T C = -C\gamma(u)$. Hence $\gamma(u)^T C\gamma(u) = -C\gamma(u)\gamma(u) = -\eta(u,u)\, C$. In $g^T C g = \gamma(u_k)^T\cdots\gamma(u_1)^T\, C\,\gamma(u_1)\cdots\gamma(u_k)$ apply this to the innermost pair, then to the next, and so on: each factor contributes $-\eta(u_j,u_j)$. Consequence: a product of exponentials has $g^T C g = +C$, but $g = \gamma^{(x1)}\gamma^{(x4)}$, an element of Spin(4,4) with $k = 2$ and $N = (+1)(-1) = -1$, has $g^T C g = -C$. **So Spin(4,4) contains elements that are not products of exponentials.** Section 5.23 finds all of them.

Determinant 1. Every gamma has determinant $+1$ as a 16×16 matrix (Section 5.3, Rule 6), and so has every product of gammas, every $\gamma(u)$ of a unit vector (its square is ± 1 and its trace 0) and every element of Pin(4,4). So the words determinant 1 in the author's statement about Spin(4,4) refer to the vector matrix Λ in O(4,4), never to the spinor matrix itself.

5.19 Example: Notebook 05d computes spin transformations

Notebook 05d builds the 28 generators, repeats the recorded so(4,4) rules (784 pairs), the vector rule (512 triples) and the invariance of C, sorts the 28 planes into 12 rotations and 16 boosts, compares the power series of the exponential with the closed formulas, computes the vector matrices by the trace formula, shows the half angle and the sign -1 after a turn by 2π, follows a unit vector around a circle and along hyperbolas, measures which transformations keep the forms of C and B, and checks the reflections, the spinor norm, the double cover and the determinants. It draws six figures and ends with ALL 20 CHECKS PASSED (notebook 05d).

5.20 How to run Notebook 05d

Step 1. What this notebook does and what it needs.

Notebook 05d (Spin(4,4) transformations: rotations, boosts, reflections and the double cover) is the file `Revision/textbook/notebooks/05d_spin_transformations.ipynb` of the repository Dirac_claude. It builds the 28 generators S^ab = (1/4)(gamma^a gamma^b - gamma^b gamma^a) from the Revision gammas, checks the recorded commutation relations (the Lie algebra so(4,4), the action on the gammas, the invariance of the charge matrix C and of the chirality), sorts the 28 planes into 12 rotations and 16 boosts, computes the finite transformations exp(theta S^ab) by their power series and by the closed formulas with half angles, shows that a rotation by 2 pi multiplies every spinor by -1 while it returns every vector to itself (the double cover), computes the 8 by 8 matrices by which spinor transformations move vectors, checks which transformations keep the forms of C and of B, and checks reflections, the spinor norm and the determinants. Six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05d_spin_transformations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05d_spin_transformations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05d_spin_transformations.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/05d.captions.json`
- `Revision/textbook/figures/05d_1_plane_types.png`
- `Revision/textbook/figures/05d_2_half_angles.png`
- `Revision/textbook/figures/05d_3_rotation_matrices.png`
- `Revision/textbook/figures/05d_4_orbits.png`
- `Revision/textbook/figures/05d_5_invariant_forms.png`
- `Revision/textbook/figures/05d_6_vector_matrices.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05d exist
ALL 20 CHECKS PASSED (notebook 05d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/05d_spin_transformations.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.

- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05d_spin_transformations.ipynb
python -m nbconvert --execute --inplace 05d_spin_transformations.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming `Revision/algebra/gammas.json`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

5.21 Notebook 05d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05d_spin_transformations.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A **spinor transformation** is a $16 \times 16$ matrix $R$ that acts on the 16
components of the spinor field, $\Psi \to R\Psi$, and at the same time turns the
eight coordinate directions into each other. The transformations that can be reached
continuously from the identity are built from the 28 **generators**
```

```
$S^{ab} = \tfrac14[\gamma^a, \gamma^b]$ as exponentials $R = \exp(\theta S^{ab})$
and products of such exponentials. This notebook

1. builds the 28 generators from the Revision gammas and repeats the recorded
   checks: they obey the commutation rules of the Lie algebra so(4,4), they turn
   the gammas into each other like the components of a vector, they keep the
   bilinear $\bar\Psi\Psi = \Psi^\dagger C\Psi$ and they commute with the chirality
   $\Gamma$;
2. sorts the 28 coordinate planes $(a, b)$ into 12 **rotations** and 16 **boosts**;
3. computes $\exp(\theta S^{ab})$ twice, by its power series and by the closed
   formulas $\cos\tfrac\theta2 + \gamma^a\gamma^b\sin\tfrac\theta2$ (rotation) and
   $\cosh\tfrac\theta2 + \gamma^a\gamma^b\sinh\tfrac\theta2$ (boost);
4. computes how $R$ moves the eight directions (an $8 \times 8$ matrix $\Lambda$),
   and shows that a rotation by $2\pi$ brings every vector back but multiplies every
   spinor by $-1$: the spinor group is a **double cover**;
5. checks which transformations keep the form of $C$ (all of them) and of $B =
   -iC\gamma^{(x4)}$ (only those that do not involve the time $x4$);
6. checks reflections, the *spinor norm* and the determinants.

Every check that repeats a recorded check prints the record file and the check
name. Six teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 05d (Spin(4,4) transformations: rotations, boosts, reflections and the double
cover) is the file ‘Revision/textbook/notebooks/05d_spin_transformations.ipynb‘ of the
repository Dirac_claude. It builds the 28 generators S^ab = (1/4)(gamma^a gamma^b -
gamma^b gamma^a) from the Revision gammas, checks the recorded commutation relations (the
Lie algebra so(4,4), the action on the gammas, the invariance of the charge matrix C and
of the chirality), sorts the 28 planes into 12 rotations and 16 boosts, computes the
finite transformations exp(theta S^ab) by their power series and by the closed formulas
with half angles, shows that a rotation by 2 pi multiplies every spinor by -1 while it
returns every vector to itself (the double cover), computes the 8 by 8 matrices by which
spinor transformations move vectors, checks which transformations keep the forms of C and
of B, and checks reflections, the spinor norm and the determinants. Six teaching plots.
It needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.
```

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another

notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 05d_spin_transformations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 05d_spin_transformations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05d_spin_transformations.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05d.captions.json‘
- ‘Revision/textbook/figures/05d_1_plane_types.png‘
- ‘Revision/textbook/figures/05d_2_half_angles.png‘
- ‘Revision/textbook/figures/05d_3_rotation_matrices.png‘
- ‘Revision/textbook/figures/05d_4_orbits.png‘
- ‘Revision/textbook/figures/05d_5_invariant_forms.png‘
- ‘Revision/textbook/figures/05d_6_vector_matrices.png‘

It changes no other file of the repository; running it headless or saving it in

JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05d exist
ALL 20 CHECKS PASSED (notebook 05d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/05d_spin_transformations.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 05d_spin_transformations.ipynb
  python -m nbconvert --execute --inplace 05d_spin_transformations.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the

  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming ‘Revision/algebra/gammas.json‘: the notebook was opened
  outside the repository, or the repository is incomplete; clone the repository again and
  open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 05d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05d (Spin(4,4) transformations: rotations, boosts, reflections and the double
# cover) is the file Revision/textbook/notebooks/05d_spin_transformations.ipynb of the
# repository Dirac_claude. It builds the 28 generators S^ab = (1/4)(gamma^a gamma^b -
# gamma^b gamma^a) from the Revision gammas, checks the recorded commutation relations
# (the Lie algebra so(4,4), the action on the gammas, the invariance of the charge matrix
# C and of the chirality), sorts the 28 planes into 12 rotations and 16 boosts, computes
# the finite transformations exp(theta S^ab) by their power series and by the closed
# formulas with half angles, shows that a rotation by 2 pi multiplies every spinor by -1
# while it returns every vector to itself (the double cover), computes the 8 by 8
# matrices by which spinor transformations move vectors, checks which transformations
# keep the forms of C and of B, and checks reflections, the spinor norm and the
# determinants. Six teaching plots. It needs a computer with Windows 11, macOS or Linux,
# an internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
```

```
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05d_spin_transformations.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
```

```
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05d_spin_transformations.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 05d_spin_transformations.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/05d.captions.json
# - Revision/textbook/figures/05d_1_plane_types.png
# - Revision/textbook/figures/05d_2_half_angles.png
# - Revision/textbook/figures/05d_3_rotation_matrices.png
# - Revision/textbook/figures/05d_4_orbits.png
# - Revision/textbook/figures/05d_5_invariant_forms.png
# - Revision/textbook/figures/05d_6_vector_matrices.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the six figure files of notebook 05d exist
#     ALL 20 CHECKS PASSED (notebook 05d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
```

```
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05d_spin_transformations.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05d_spin_transformations.ipynb
#     python -m nbconvert --execute --inplace 05d_spin_transformations.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming Revision/algebra/gammas.json: the notebook was opened
#   outside the repository, or the repository is incomplete; clone the repository again
#   and open the notebook from its folder Revision/textbook/notebooks.
#

## 3. The words used in this notebook

- **Commutator** $[M, N] = MN - NM$.
- **Generators** $S^{ab} = \tfrac14[\gamma^a, \gamma^b]$; for $a \neq b$ the two
  gammas anticommute and $S^{ab} = \tfrac12\gamma^a\gamma^b$. There are 28 of them
  ($a$ before $b$ in the order $x0, \dots, x7$).
- **Lie algebra so(4,4)**: the commutation rules $[S^{ab}, S^{cd}] = \eta^{bc}S^{ad}
  - \eta^{ac}S^{bd} - \eta^{bd}S^{ac} + \eta^{ad}S^{bc}$ of the 28 generators.
- **Exponential of a matrix**: $\exp(M) = 1 + M + \tfrac12 M^2 + \tfrac16 M^3 +
  \dots = \sum_{k \ge 0} M^k/k!$, the same power series as for $e^x$.
- **Hyperbolic functions**: $\cosh x = \tfrac12(e^x + e^{-x})$ and $\sinh x =
  \tfrac12(e^x - e^{-x})$; $\cosh^2 x - \sinh^2 x = 1$.
- **Rotation**: a transformation in a plane of two directions of the same kind
  (both space-like or both time-like); it turns them by an angle $\theta$ and comes
  back after $2\pi$.
- **Boost**: a transformation in a plane of one space-like and one time-like
  direction; it mixes them with $\cosh\theta$ and $\sinh\theta$ and never comes
  back ($\theta$ is the *rapidity*).
- **Vector**, $\gamma(v)$: eight numbers $v_a$; the matrix $\gamma(v) =
  \sum_a v_a\gamma^a$. The **metric product** is $\eta(u, v) = \sum_a \eta_{aa}u_a
  v_a$; $u$ is a **unit vector** when $\eta(u, u) = +1$ or $-1$.
- **O(4,4), SO(4,4)**: the real $8 \times 8$ matrices $\Lambda$ with $\Lambda^T\eta
  \Lambda = \eta$ (they keep the metric product); SO(4,4): those with determinant
  $+1$.
- **Reflection** $R_u$ along a unit vector $u$: $R_u v = v - 2\,\eta(u, v)\,u/
  \eta(u, u)$; it reverses $u$ and keeps every direction orthogonal to $u$.
- **Pin(4,4)**: all products $\gamma(u_1)\cdots\gamma(u_k)$ of unit vectors;
  **Spin(4,4)**: those with an even number $k$ of factors.
- **Spinor norm** $N(g) = \eta(u_1, u_1)\cdots\eta(u_k, u_k)$ of such a product.
- **Double cover**: two spinor matrices, $R$ and $-R$, move the vectors in the
  same way.
```

Text cell:

```
## 4. The physical and mathematical situation

**The exponential in closed form.** Fix a plane $(a, b)$ with $a \neq b$ and put
$J = \gamma^a\gamma^b = 2S^{ab}$. Then $\theta S^{ab} = \tfrac\theta2 J$ and

$$JJ = \gamma^a\gamma^b\gamma^a\gamma^b = -\gamma^a\gamma^a\gamma^b\gamma^b =
  -\eta_{aa}\eta_{bb}\,1 ,$$

using $\gamma^b\gamma^a = -\gamma^a\gamma^b$ and $\gamma^a\gamma^a = \eta_{aa}1$.

- If $\eta_{aa}\eta_{bb} = +1$ (both space-like or both time-like): $JJ = -1$, so
```

```
  $J^{2n} = (-1)^n$ and $J^{2n+1} = (-1)^n J$. Splitting the series of $\exp$ into
  even and odd powers,
  $\exp(\tfrac\theta2 J) = \sum_n \frac{(-1)^n(\theta/2)^{2n}}{(2n)!} + J\sum_n
  \frac{(-1)^n(\theta/2)^{2n+1}}{(2n+1)!} = \cos\tfrac\theta2 + J\sin\tfrac\theta2$
  (the power series of cosine and sine): a **rotation**.
- If $\eta_{aa}\eta_{bb} = -1$: $JJ = +1$, all signs are $+$, and $\exp(\tfrac\theta2
  J) = \cosh\tfrac\theta2 + J\sinh\tfrac\theta2$: a **boost**.

**How the directions move.** From the Clifford relation, $[S^{ab}, \gamma^c] =
\eta^{bc}\gamma^a - \eta^{ac}\gamma^b$. For the plane $(x1, x2)$ this gives
$[S, \gamma^{(x1)}] = -\gamma^{(x2)}$ and $[S, \gamma^{(x2)}] = \gamma^{(x1)}$.
The functions $f(\theta) = R\gamma^{(x1)}R^{-1}$ and $g(\theta) =
R\gamma^{(x2)}R^{-1}$ with $R = \exp(\theta S)$ then obey $f' = -g$ and $g' = f$
(the derivative of $R$ is $RS$, of $R^{-1}$ it is $-SR^{-1}$), with the solution
$f = \cos\theta\,\gamma^{(x1)} - \sin\theta\,\gamma^{(x2)}$ and
$g = \sin\theta\,\gamma^{(x1)} + \cos\theta\,\gamma^{(x2)}$: the directions turn by
the **full** angle $\theta$, while $R$ contains only the **half** angle. At
$\theta = 2\pi$ the directions are back, but $R = \cos\pi + J\sin\pi = -1$.

**Reading off the vector matrix.** Write $R\gamma^cR^{-1} = \sum_d \Lambda_{dc}
\gamma^d$. Because $\mathrm{tr}(\gamma^d\gamma^e) = 16\,\eta^{de}$ (for $d \neq e$
the trace of an anticommuting product is zero, since $\mathrm{tr}(MN) =
\mathrm{tr}(NM)$ gives $\mathrm{tr}(\gamma^d\gamma^e) =
-\mathrm{tr}(\gamma^d\gamma^e)$; for $d = e$ it is the trace of $\eta_{dd}1$),
taking the trace with $\gamma^d$ gives $\Lambda_{dc} = \eta_{dd}\,
\mathrm{tr}(\gamma^d R\gamma^c R^{-1})/16$.

**Reflections.** For a unit vector $u$, from $\gamma(u)\gamma(v) + \gamma(v)
\gamma(u) = 2\eta(u, v)1$ and $\gamma(u)^{-1} = \gamma(u)/\eta(u, u)$:
$\gamma(u)\gamma(v)\gamma(u)^{-1} = 2\eta(u, v)\gamma(u)/\eta(u, u) - \gamma(v) =
-\gamma(R_u v)$. So $-\gamma(u)\gamma(v)\gamma(u)^{-1} = \gamma(R_uv)$:
conjugation by a unit vector is a reflection, up to the sign.

**The spinor norm.** For $g = \gamma(u_1)\cdots\gamma(u_k)$: $g^TCg = (-1)^k
N(g)\,C$. (Each factor gives $\gamma(u)^TC\gamma(u) = -\eta(u,u)C$, from
$\gamma(u)^TC = -C\gamma(u)$, which follows from $C\gamma^aC^{-1} =
-(\gamma^a)^T$.) A product of exponentials keeps $C$: if $R_1^TCR_1 = C$ and
$R_2^TCR_2 = C$, then $(R_1R_2)^TC(R_1R_2) = R_2^TR_1^TCR_1R_2 = C$.
```

Text cell:

```
## 5. The gammas and the recorded checks

The next cell reads the gammas (exact whole numbers) from the Revision record and
the two algebra reports, and defines: the helpers `recorded(key, name)` (true when
the report `key`, "python" or "wolfram", holds the check `name` with the verdict
pass) and `record_of(key, name)` (the text printed after "reproduces"); the helper
`check_reproduces(condition, name, record)`, which is `check` for a check that
reproduces a Revision record, printed in one piece (it lets `check` print the PASS
line and the line "reproduces ..." into a text buffer with
`contextlib.redirect_stdout` and sends both with one `sys.stdout.write`, because
Jupyter delivers printed text in pieces); the $8 \times 8$ metric `ETA_MATRIX`
$= \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$, $C$, $\Gamma$ and $B$. Then it checks
```

the Clifford relation.

```

Text cell:

```
## 6. The 28 generators and their commutation rules

The next cell builds $S^{ab}$ for all 64 ordered pairs (with $S^{aa} = 0$), as
arrays of floating-point numbers. Their entries are $0$ and $\pm\tfrac12$, and every
product and sum below involves only halves and quarters, which the computer stores
**exactly** (they are sums of powers of 2), so `np.array_equal` compares exactly. It
checks three recorded facts:

1. $S^{ab} = -S^{ba}$ and $S^{ab} = \tfrac12\gamma^a\gamma^b$ for $a \neq b$;
2. the so(4,4) rules $[S^{ab}, S^{cd}] = \eta^{bc}S^{ad} - \eta^{ac}S^{bd} -
   \eta^{bd}S^{ac} + \eta^{ad}S^{bc}$ for all $28 \times 28 = 784$ pairs of
   generators;
3. $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b$ for all
   $8 \times 8 \times 8 = 512$ triples: the gammas turn like the components of a
   vector.
```

In [3]:

```
S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4.0
     for a in COORDS for b in COORDS}  # all 64 ordered pairs

## 7. Rotations and boosts

The next cell computes $JJ$ for $J = \gamma^a\gamma^b$ in each of the 28 planes and
checks $JJ = -\eta_{aa}\eta_{bb}1$; it calls the plane a rotation when
$\eta_{aa}\eta_{bb} = +1$ and a boost when $\eta_{aa}\eta_{bb} = -1$, counts them
and draws the table. Expected: the 6 planes inside $\{x0, x1, x2, x3\}$ and the 6
inside $\{x4, x5, x6, x7\}$ are rotations (12); the $4 \times 4 = 16$ mixed planes
are boosts. Note that a plane of two times, such as $(x4, x5)$, is a rotation.
```

In [5]:

## 8. The exponential: power series and closed formula

The next cell defines two ways of computing $R = \exp(\theta S^{ab})$: the power
series summed up to 80 terms (each term is the previous one times $M/k$), and the
closed formula of section 4. It compares them for two rotations, $(x1, x2)$ and
$(x4, x5)$, at the angles $0.3$, $1$, $2.5$, $2\pi$ and $4\pi$, and for two boosts,
$(x1, x4)$ and $(x5, x0)$, at the rapidities $-1.5$, $0.3$, $1$ and $2.5$. The
largest difference of any entry must be below $10^{-10}$ (the series is summed in
floating-point numbers).
```

In [6]:

```

## 9. How the directions move, and the sign after 2 pi

The next cell defines ‘vector_matrix(R)‘, the $8 \times 8$ matrix $\Lambda$ with
$R\gamma^cR^{-1} = \sum_d\Lambda_{dc}\gamma^d$, read off with the trace formula of
section 4, and checks for the rotation in the plane $(x1, x2)$ at nine angles that:
the sum $\sum_d \Lambda_{dc}\gamma^d$ rebuilds $R\gamma^cR^{-1}$; $\Lambda$ is the
rotation by the full angle $\theta$ (entries $\cos\theta$ and $\pm\sin\theta$ in the
$(x1, x2)$ block, the identity elsewhere); $\Lambda^T\eta\Lambda = \eta$ and
$\det\Lambda = 1$ (it lies in SO(4,4)). Then it checks the double cover:
$R(2\pi) = -1$ and $R(4\pi) = +1$, while $\Lambda(2\pi) = \Lambda(4\pi) = 1$.
```

In [7]:

## 10. Circles and hyperbolas

A rotation keeps $v_1^2 + v_2^2$, a boost keeps $v_1^2 - v_4^2$ (the metric product
in that plane, because $\eta_{x4\,x4} = -1$). The next cell moves the unit vector
$e_{x1}$ with the rotation in $(x1, x2)$ for $\theta$ from 0 to $2\pi$ (it runs
around a circle), and the unit vectors $e_{x1}$ and $e_{x4}$ with the boost in
$(x1, x4)$ for $\theta$ from $-2$ to 2 (they run along the two branches of the
hyperbolas $v_1^2 - v_4^2 = +1$ and $= -1$). The vector matrices are again computed
from the spinor matrices.
```

In [10]:

```
# column k of a vector matrix is the image of e_xk; its entry 1 is v_1, entry 4 v_4
circle = np.array([vector_matrix(spin_transformation("x1", "x2", th))[:, 1]
                   for th in np.linspace(0.0, 2 * np.pi, 121)])  # images of e_x1
hyper_space = np.array([vector_matrix(spin_transformation("x1", "x4", th))[:, 1]
                        for th in np.linspace(-2.0, 2.0, 121)])  # images of e_x1
hyper_time = np.array([vector_matrix(spin_transformation("x1", "x4", th))[:, 4]

## 11. Which forms are kept: C always, B only away from the time x4

Because $(S^{ab})^TC + CS^{ab} = 0$ for every generator, every exponential keeps the
form of $C$: $R^TCR = C$. The form of $B$ (the charge density $\Psi^\dagger B\Psi$)
is different: the recorded check states that $(S^{ab})^\dagger B + BS^{ab} = 0$
holds exactly for the 21 generators that do not involve $x4$, and that for the 7
generators $S^{(x4)\,b}$ it equals $iC\gamma^b \neq 0$. The next cell checks this
generator by generator, and then for finite transformations: $R^TCR - C$ and
$R^\dagger BR - B$ ($R$ is real, so $R^\dagger = R^T$) for all 28 planes at
$\theta = 0.7$.
```

PASS the six figure files of notebook 05d exist
ALL 20 CHECKS PASSED (notebook 05d)
```

Text cell:

```
## 15. What this notebook showed

- The 28 generators $S^{ab} = \tfrac12\gamma^a\gamma^b$ of the Revision gammas obey
  the rules of the Lie algebra so(4,4), turn the gammas like a vector, keep the form
  of $C$ and commute with $\Gamma$, as the Revision record states.
- 12 coordinate planes give rotations ($\cos$, $\sin$ of half the angle), 16 give
  boosts ($\cosh$, $\sinh$ of half the rapidity); the closed formulas agree with
  the power series of the exponential.
- The spinor matrix contains the half angle and the vector matrix the full angle:
  a rotation by $2\pi$ returns every direction but gives $R = -1$ on spinors; only
  $4\pi$ gives $R = +1$. $R$ and $-R$ move the vectors in the same way: the spinor
  group is a double cover of the group of vector transformations.
- Every spinor transformation keeps the form $\Psi^\dagger C\Psi$; the charge
  density $\Psi^\dagger B\Psi$ is kept only by the 21 generators (and their
  exponentials) that do not involve the time $x4$.
- Conjugation by a unit vector is a reflection (up to a sign), with determinant
  $-1$; the spinor norm $g^TCg = (-1)^kN(g)C$ holds; $\gamma^{(x1)}\gamma^{(x4)}$
  lies in Spin(4,4) but is not a product of exponentials; $\Gamma$ reverses all
  eight directions; every gamma has determinant $+1$ as a $16 \times 16$ matrix.
```

5.22 Line-by-line walk-through of Notebook 05d

The notebook has 17 code cells. In [1] is the set-up cell of Section 5.10 with `NOTEBOOK_ID = "05d"`; its comments repeat the instructions of Section 5.20. Docstrings are left out of the quotations and long captions are replaced by a line `...`), as in Section 5.10.

In [2], the gammas, C, Γ, B and the recorded checks.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
ETA_MATRIX = np.diag([float(ETA[x]) for x in COORDS])  # the 8 x 8 metric eta
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)
```

As in Notebook 05a, the record of the gammas is read. New is `ETA_MATRIX`, the 8×8 diagonal matrix η with floating-point entries (`np.diag` of the list of the eight signs), used for the metric product of vectors below.

```
C = gamma["x0"] @ gamma["x1"] @ gamma["x2"] @ gamma["x3"]  # the charge matrix
Gamma = I16
for x in ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]:
    Gamma = Gamma @ gamma[x]  # the chirality, the product of all eight gammas
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4)
```

C, Γ and B are built as in Sections 5.4 to 5.6; the loop multiplies the eight gammas in the author's order, starting from the identity.

```
REPORT_FILES = {"python": "Revision/algebra/reports/python-algebra.json",
                "wolfram": "Revision/algebra/reports/wolfram-algebra.json"}
VERDICTS = {}  # (report key, check name) -> (verdict in lower case, detail text)
for key, path in REPORT_FILES.items():
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in report_data["checks"]:
        VERDICTS[(key, entry["name"])] = (entry["verdict"].lower(), entry["detail"])

def recorded(key, name):
    return VERDICTS[(key, name)][0] == "pass"

def record_of(key, name):
    return f"{REPORT_FILES[key]}, check {name}"

def check_reproduces(condition, name, record):
    collected = io.StringIO()
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together
```

The two reports and the helpers `recorded`, `record_of` and `check_reproduces`, exactly as in Notebook 05a (Section 5.10, In [3]).

```
def eta(a, b):
    return ETA[a] if a == b else 0

check_reproduces(all(np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                                    2 * eta(a, b) * I16) for a in COORDS for b in COORDS)
                 and recorded("python", "clifford_relation"),
                 "{gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs",
                 record=record_of("python", "clifford_relation"))
```

`eta(a, b)` is η^{ab}: η_{aa} for equal directions and 0 otherwise. The check is the Clifford relation for all 64 pairs.

In [3], the generators and their rules.

```
S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4.0
     for a in COORDS for b in COORDS}  # all 64 ordered pairs
```

```
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 pairs

def commutator(m, n):
    return m @ n - n @ m
```

`S` holds S^{ab} for all 64 ordered pairs (including $S^{aa} = 0$), as floating-point arrays with the entries 0 and $\pm\frac{1}{2}$. Every sum and product below involves only halves and quarters, which the computer stores exactly (they are sums of powers of 2), so comparisons with `np.array_equal` are exact. `pairs` lists the 28 planes, and `commutator` is $[m, n] = mn - nm$.

```
definition_ok = all(np.array_equal(S[(a, b)], -S[(b, a)]) for a in COORDS
                    for b in COORDS) and all(
    np.array_equal(S[(a, b)], gamma[a] @ gamma[b] / 2.0) for a, b in pairs)
check_reproduces(len(pairs) == 28 and definition_ok
                 and recorded("python", "S_definition"),
                 "S^ab = -S^ba and S^ab = (1/2) gamma^a gamma^b: 28 independent "
                 "generators",
                 record=record_of("python", "S_definition"))
```

The check confirms $S^{ab} = -S^{ba}$ for all 64 pairs and $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$ for the 28 planes.

```
algebra_failures = 0
for a, b in pairs:
    for c, d in pairs:
        right = (eta(b, c) * S[(a, d)] - eta(a, c) * S[(b, d)]
                 - eta(b, d) * S[(a, c)] + eta(a, d) * S[(b, c)])
        if not np.array_equal(commutator(S[(a, b)], S[(c, d)]), right):
            algebra_failures += 1
say(f"so(4,4) rules tested for {len(pairs) ** 2} pairs; failures {algebra_failures}")
check_reproduces(algebra_failures == 0 and recorded("python", "S_lorentz_algebra")
                 and recorded("wolfram", "S_Lorentz_algebra"),
                 "[S^ab, S^cd] = eta^bc S^ad - eta^ac S^bd - eta^bd S^ac + eta^ad S^bc",
                 record=record_of("python", "S_lorentz_algebra"))
```

For each of the $28 \times 28 = 784$ pairs of planes the right side of the so(4,4) rule is assembled and compared with the commutator; failures are counted. The printed line reports 784 pairs and 0 failures.

```
vector_failures = sum(
    not np.array_equal(commutator(S[(a, b)], gamma[c]),
                       eta(b, c) * gamma[a] - eta(a, c) * gamma[b])
    for a in COORDS for b in COORDS for c in COORDS)
say(f"vector rule tested for 512 triples; failures {vector_failures}")
check_reproduces(vector_failures == 0 and recorded("python", "S_vector_action")
                 and recorded("wolfram", "S_gamma_commutator"),
                 "[S^ab, gamma^c] = eta^bc gamma^a - eta^ac gamma^b for all 512 triples",
                 record=record_of("python", "S_vector_action"))
```

The vector rule of Section 5.12 is tested for all $8 \times 8 \times 8 = 512$ triples; `sum` of true and false values counts the true ones (a failure counts 1). The printed line reports 0 failures.

In [4], the invariances of the generators.

```
check_reproduces(all(not ((S[k].T @ C + C @ S[k]).any()) for k in S)
                 and all(not commutator(Gamma, S[k]).any() for k in S)
                 and recorded("python", "S_preserves_C_and_commutes_with_Gamma"),
                 "(S^ab)^T C + C S^ab = 0 and [Gamma, S^ab] = 0 for all a, b",
                 record=record_of("python", "S_preserves_C_and_commutes_with_Gamma"))
```

For all 64 keys `k` of `S` the cell checks $(S^{ab})^T C + C S^{ab} = 0$ (so the scalar does not change to first order) and $[\Gamma, S^{ab}] = 0$ (so the halves are kept).

In [5], rotations and boosts.

```
kind = {}  # (a, b) -> +1 for a rotation, -1 for a boost
squares_ok = True
for a, b in pairs:
    J = gamma[a] @ gamma[b]
    squares_ok &= np.array_equal(J @ J, -ETA[a] * ETA[b] * I16)
    kind[(a, b)] = ETA[a] * ETA[b]
rotations = [p for p in pairs if kind[p] == 1]
boosts = [p for p in pairs if kind[p] == -1]
say(f"rotations: {len(rotations)}; boosts: {len(boosts)}")
say("rotation planes: " + " ".join(f"({a},{b})" for a, b in rotations))
check(squares_ok and len(rotations) == 12 and len(boosts) == 16,
      "(gamma^a gamma^b)^2 = -eta_aa eta_bb: 12 rotation planes and 16 boost planes")
```

For each plane $J = \gamma^a \gamma^b$ is squared and compared with $-\eta_{aa}\eta_{bb}1$; the plane is a rotation when $\eta_{aa}\eta_{bb} = +1$ and a boost otherwise. The printed lines show 12 rotations and 16 boosts and list the rotation planes: the six inside $\{x0, x1, x2, x3\}$ and the six inside $\{x4, x5, x6, x7\}$.

```
from matplotlib.colors import LinearSegmentedColormap

SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
table = np.zeros((8, 8))
for (a, b), value in kind.items():
    i, j = COORDS.index(a), COORDS.index(b)
    table[i, j] = table[j, i] = value  # the same plane in both orders
fig, ax = plt.subplots(figsize=(6.4, 5.6))
ax.imshow(table, cmap=SIGNS, vmin=-1, vmax=1)
for i in range(8):
    for j in range(8):
        word = "" if i == j else ("rot" if table[i, j] == 1 else "boost")
        ax.text(j, i, word, ha="center", va="center", color="white", fontsize=8,
                fontweight="bold")
for k in range(1, 8):
    ax.axhline(k - 0.5, color="white", linewidth=2)
    ax.axvline(k - 0.5, color="white", linewidth=2)
ax.set_xticks(range(8), COORDS)
```

```
ax.set_yticks(range(8), COORDS)
ax.set_title("The 28 planes: rotations (red) and boosts (blue)")
ax.grid(False)
save_figure(fig, "plane_types",
            ...)
```

The kinds are written into an 8×8 table, each plane in both orders (`COORDS.index(a)` is the position of a name in the list; `x = y = value` sets both entries). The table is drawn with the colour map of the heat maps (red $+1$, blue -1, grey 0 on the diagonal), with the word rot or boost in each square and white gaps between the squares. `05d_1_plane_types.png` shows two red 4×4 squares of rotations, for $\{x0, x1, x2, x3\}$ and for the four times, and blue boosts wherever a space-like direction meets a time-like one.

In [6], the exponential two ways.

```
def exp_series(M, terms=80):
    result = np.eye(M.shape[0])
    term = np.eye(M.shape[0])
    for k in range(1, terms):
        term = term @ M / k  # M^k / k! from M^(k-1) / (k-1)!
        result = result + term
    return result
```

`exp_series` sums the power series of the exponential up to the term $M^{79}/79!$. Each term is computed from the previous one by multiplying by M and dividing by k, because $M^k/k! = (M^{k-1}/(k-1)!)\, M/k$.

```
def spin_transformation(a, b, theta):
    J = (gamma[a] @ gamma[b]).astype(float)  # J = 2 S^ab
    if ETA[a] * ETA[b] == 1:  # J J = -1: a rotation
        return np.cos(theta / 2) * np.eye(16) + np.sin(theta / 2) * J
    return np.cosh(theta / 2) * np.eye(16) + np.sinh(theta / 2) * J  # a boost
```

`spin_transformation(a, b, theta)` is the closed formula of Section 5.18: $\cos\frac{\theta}{2}\,1 + \sin\frac{\theta}{2}\,J$ for a rotation and $\cosh\frac{\theta}{2}\,1 + \sinh\frac{\theta}{2}\,J$ for a boost.

```
tests = [(("x1", "x2"), [0.3, 1.0, 2.5, 2 * np.pi, 4 * np.pi]),
         (("x4", "x5"), [0.3, 1.0, 2.5, 2 * np.pi, 4 * np.pi]),
         (("x1", "x4"), [-1.5, 0.3, 1.0, 2.5]),
         (("x0", "x5"), [-1.5, 0.3, 1.0, 2.5])]
largest_difference = 0.0
for (a, b), angles in tests:
    for theta in angles:
        difference = np.max(np.abs(exp_series(theta * S[(a, b)])
                                   - spin_transformation(a, b, theta)))
        largest_difference = max(largest_difference, difference)
    name = "rotation" if kind[(a, b)] == 1 else "boost"
    say(f"plane ({a},{b}), a {name}: series and closed formula compared at "
        f"{len(angles)} values")
check(largest_difference < 1e-10,
```

```
      "the power series of exp(theta S^ab) equals the closed formula with half "
      "angles (difference below 1e-10)")
```

Two rotations (one of them in the plane of two times) and two boosts are tested at several angles or rapidities; for each, the largest difference of any entry between the series and the closed formula is kept in `largest_difference`. Four lines are printed, and the check requires the largest difference to be below 10^{-10} (the series is summed in floating-point numbers, and at 4π its terms first grow large before they shrink).

In [7], the vector matrix and the sign after 2π.

```
def vector_matrix(R):
    R_inverse = np.linalg.inv(R)
    Lam = np.zeros((8, 8))
    for j, c in enumerate(COORDS):
        moved = R @ gamma[c] @ R_inverse  # where the direction c is moved to
        for i, d in enumerate(COORDS):
            Lam[i, j] = ETA[d] * np.trace(gamma[d] @ moved) / 16.0
    return Lam
```

`vector_matrix(R)` computes Λ by the trace formula of Section 5.18: for each direction c it forms $R\gamma^c R^{-1}$ (`np.linalg.inv` is the inverse matrix) and fills column c with $\eta_{dd}\,\mathrm{tr}(\gamma^d R\gamma^c R^{-1})/16$ for each row d.

```
def rebuilds(R, Lam):
    R_inverse = np.linalg.inv(R)
    return all(np.allclose(sum(Lam[i, j] * gamma[d] for i, d in enumerate(COORDS)),
                           R @ gamma[c] @ R_inverse, atol=1e-12)
               for j, c in enumerate(COORDS))
```

`rebuilds` checks that $\sum_d \Lambda_{dc}\gamma^d$ really equals $R\gamma^c R^{-1}$ for every c, that is, that the moved gamma is a combination of gammas with the coefficients read off. `np.allclose(x, y, atol=1e-12)` is true when every entry of `x` differs from that of `y` by at most about 10^{-12}.

```
rotation_ok = True
for theta in np.linspace(0.0, 2 * np.pi, 9):
    R = spin_transformation("x1", "x2", theta)
    Lam = vector_matrix(R)
    expected = np.eye(8)  # the rotation by theta in the (x1, x2) block
    expected[1, 1] = expected[2, 2] = np.cos(theta)  # rows and columns x1, x2
    expected[1, 2], expected[2, 1] = np.sin(theta), -np.sin(theta)
    rotation_ok &= (rebuilds(R, Lam) and np.allclose(Lam, expected, atol=1e-12)
                    and np.allclose(Lam.T @ ETA_MATRIX @ Lam, ETA_MATRIX)
                    and abs(np.linalg.det(Lam) - 1.0) < 1e-12)
check(rotation_ok,
      "R = exp(theta S^(x1 x2)) turns the directions x1, x2 by the full angle "
      "theta; Lambda lies in SO(4,4)")
```

For nine angles from 0 to 2π the cell computes the rotation in the plane $(x1, x2)$ and its vector matrix, and compares it with the prediction of Section 5.18: the identity except for the block of

$x1$ and $x2$, which holds $\cos\theta$ on the diagonal, $\sin\theta$ in row $x1$, column $x2$, and $-\sin\theta$ in row $x2$, column $x1$. It also checks $\Lambda^T\eta\Lambda = \eta$ and $\det\Lambda = 1$ (`np.linalg.det`): Λ lies in SO(4,4).

```
R_2pi, R_4pi = spin_transformation("x1", "x2", 2 * np.pi), spin_transformation(
    "x1", "x2", 4 * np.pi)
# Rounding leaves differences of about 1e-16, which differ between computers, so
# the cell prints only whether they are below 1e-12.
small_2pi = np.max(np.abs(R_2pi + np.eye(16))) < 1e-12
small_4pi = np.max(np.abs(R_4pi - np.eye(16))) < 1e-12
say(f"every entry of R(2 pi) + 1 is below 1e-12: {small_2pi}; "
    f"every entry of R(4 pi) - 1 is below 1e-12: {small_4pi}")
check(np.allclose(R_2pi, -np.eye(16), atol=1e-12)
      and np.allclose(R_4pi, np.eye(16), atol=1e-12)
      and np.allclose(vector_matrix(R_2pi), np.eye(8), atol=1e-12),
      "a rotation by 2 pi gives R = -1 on spinors but Lambda = 1 on vectors; by 4 pi, R "
      "= +1")
```

$R(2\pi)$ and $R(4\pi)$ are computed; $\sin\pi$ is not exactly 0 in floating-point numbers, so the cell prints only whether the entries of $R(2\pi)+1$ and $R(4\pi)-1$ are below 10^{-12} (both True). The check is the double cover: $R(2\pi) = -1$ while its vector matrix is the identity, and $R(4\pi) = +1$.

In [8], the picture of the half angles.

```
angles = np.linspace(0.0, 4 * np.pi, 241)
rapidities = np.linspace(-3.0, 3.0, 241)
vec_rot = [vector_matrix(spin_transformation("x1", "x2", th))[1, 1] for th in angles]
spin_rot = [np.trace(spin_transformation("x1", "x2", th)) / 16 for th in angles]
vec_boost = [vector_matrix(spin_transformation("x1", "x4", th))[1, 1]
             for th in rapidities]
spin_boost = [np.trace(spin_transformation("x1", "x4", th)) / 16 for th in rapidities]
check(np.allclose(vec_rot, np.cos(angles)) and np.allclose(spin_rot, np.cos(angles / 2))
      and np.allclose(vec_boost, np.cosh(rapidities))
      and np.allclose(spin_boost, np.cosh(rapidities / 2)),
      "vectors move with cos(theta), cosh(theta); spinors with the half angle")
```

For 241 angles from 0 to 4π (rotation in $(x1, x2)$) and 241 rapidities from -3 to 3 (boost in $(x1, x4)$), the cell computes the vector entry $\Lambda_{x1,x1}$ and the spinor quantity $\operatorname{tr} R/16$; since $\operatorname{tr} J = 0$ (Rule 5), $\operatorname{tr} R/16$ is $\cos\frac{\theta}{2}$ or $\cosh\frac{\theta}{2}$. The check compares the four lists with $\cos\theta$, $\cos\frac{\theta}{2}$, $\cosh\theta$ and $\cosh\frac{\theta}{2}$.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.4))
axes[0].plot(angles, vec_rot, color="#2a78d6", linewidth=2,
             label=r"vector: $\Lambda_{x1,x1} = \cos\theta$")
axes[0].plot(angles, spin_rot, color="#eb6834", linewidth=2, linestyle="--",
             label=r"spinor: $\mathrm{tr}\,R/16 = \cos(\theta/2)$")
axes[0].plot([2 * np.pi, 2 * np.pi], [1.0, -1.0], "o", color="black", markersize=7,
             label=r"at $2\pi$: vector back at $1$, spinor at $-1$")
axes[0].set_xticks([0, np.pi, 2 * np.pi, 3 * np.pi, 4 * np.pi],
                   ["0", r"$\pi$", r"$2\pi$", r"$3\pi$", r"$4\pi$"])
axes[0].set_xlabel(r"rotation angle $\theta$ in the plane $(x1, x2)$")
axes[0].set_ylabel("value")
axes[0].set_title("A rotation: the spinor needs $4\\pi$ to come back")
```

```
axes[0].legend(loc="upper center", bbox_to_anchor=(0.5, -0.17))
axes[1].plot(rapidities, vec_boost, color="#2a78d6", linewidth=2,
             label=r"vector: $\Lambda_{x1,x1} = \cosh\theta$")
axes[1].plot(rapidities, spin_boost, color="#eb6834", linewidth=2, linestyle="--",
             label=r"spinor: $\mathrm{tr}\,R/16 = \cosh(\theta/2)$")
axes[1].set_xlabel(r"rapidity $\theta$ in the plane $(x1, x4)$")
axes[1].set_title("A boost: never periodic;\nthe spinor grows half as fast")
axes[1].legend(loc="upper center", bbox_to_anchor=(0.5, -0.17))
save_figure(fig, "half_angles",
            ...)
```

Two pictures: on the left the two rotation curves and two black dots at $\theta = 2\pi$ (the vector entry at 1, the spinor quantity at -1); on the right the two boost curves. The tick marks of the left horizontal axis are at multiples of π; `"\n"` in a title starts a new line; both legends go below their pictures. In `05d_2_half_angles.png` the solid cosine completes two periods over 4π while the dashed one completes one: the spinor needs 4π to come back.

In [9], the rotation matrices.

```
fig, axes = plt.subplots(1, 4, figsize=(13.0, 3.9))
for k, (ax, th, label) in enumerate(zip(
        axes, [0.0, np.pi, 2 * np.pi, 4 * np.pi], ["0", r"\pi", r"2\pi", r"4\pi"])):
    image = ax.imshow(spin_transformation("x1", "x2", th), cmap=SIGNS, vmin=-1,
                      vmax=1)
    ax.set_title(rf"$R(\theta)$ at $\theta = {label}$")
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.set_xlabel("column")
    if k == 0:
        ax.set_ylabel("row")
    ax.grid(False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
check(np.allclose(spin_transformation("x1", "x2", np.pi),
                  gamma["x1"] @ gamma["x2"], atol=1e-12),
      "R(pi) = gamma^(x1) gamma^(x2) for the rotation in the plane (x1, x2)")
save_figure(fig, "rotation_matrices",
            ...)
```

The loop draws $R(\theta)$ at $\theta = 0$, π, 2π and 4π as heat maps (the `zip` runs through the four axes, the four angles and their labels together). The check confirms $R(\pi) = \gamma^{(x1)}\gamma^{(x2)}$ (because $\cos\frac{\pi}{2} = 0$ and $\sin\frac{\pi}{2} = 1$). In `05d_3_rotation_matrices.png` the first picture is the identity (red diagonal), the second the signed permutation $\gamma^{(x1)}\gamma^{(x2)}$, the third minus the identity (blue diagonal) and the fourth the identity again.

In [10], circles and hyperbolas.

```
# column k of a vector matrix is the image of e_xk; its entry 1 is v_1, entry 4 v_4
circle = np.array([vector_matrix(spin_transformation("x1", "x2", th))[:, 1]
                   for th in np.linspace(0.0, 2 * np.pi, 121)])  # images of e_x1
hyper_space = np.array([vector_matrix(spin_transformation("x1", "x4", th))[:, 1]
                        for th in np.linspace(-2.0, 2.0, 121)])  # images of e_x1
```

```
hyper_time = np.array([vector_matrix(spin_transformation("x1", "x4", th))[:, 4]
                       for th in np.linspace(-2.0, 2.0, 121)])  # images of e_x4
check(np.allclose(circle[:, 1] ** 2 + circle[:, 2] ** 2, 1.0)
      and np.allclose(hyper_space[:, 1] ** 2 - hyper_space[:, 4] ** 2, 1.0)
      and np.allclose(hyper_time[:, 1] ** 2 - hyper_time[:, 4] ** 2, -1.0),
      "rotations keep v1^2 + v2^2, boosts keep v1^2 - v4^2")
```

Column c of a vector matrix is the image of the basic unit vector e_c; Python counts the positions from 0, so position k is the direction xk, `[:, 1]` is the column of $x1$ and `[:, 4]` that of $x4$, and in a column the entries `[1]` and `[4]` are the components v_1 and v_4. The cell collects the images of e_{x1} under 121 rotations in $(x1, x2)$, and the images of e_{x1} and of e_{x4} under 121 boosts in $(x1, x4)$. The check confirms that the rotation keeps $v_1^2 + v_2^2 = 1$ and the boost keeps $v_1^2 - v_4^2$, equal to $+1$ for the image of e_{x1} and -1 for that of e_{x4}.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 5.0))
axes[0].plot(circle[:, 1], circle[:, 2], color="#2a78d6", linewidth=2)
axes[0].plot(circle[::15, 1], circle[::15, 2], "o", color="#2a78d6", markersize=8)
axes[0].set_aspect("equal")
axes[0].set_xlabel("$v_1$ (component along $x1$)")
axes[0].set_ylabel("$v_2$ (component along $x2$)")
axes[0].set_title("rotation in $(x1, x2)$: a circle")
axes[1].plot(hyper_space[:, 1], hyper_space[:, 4], color="#2a78d6", linewidth=2,
             label=r"image of $e_{x1}$: $v_1^2 - v_4^2 = 1$")
axes[1].plot(hyper_time[:, 1], hyper_time[:, 4], color="#eb6834", linewidth=2,
             label=r"image of $e_{x4}$: $v_1^2 - v_4^2 = -1$")
axes[1].plot([-4, 4], [-4, 4], ":", color="black", linewidth=1,
             label="null lines $v_4 = \\pm v_1$")
axes[1].plot([-4, 4], [4, -4], ":", color="black", linewidth=1)
axes[1].set_xlim(-4, 4)
axes[1].set_ylim(-4, 4)
axes[1].set_aspect("equal")
axes[1].set_xlabel("$v_1$ (component along $x1$)")
axes[1].set_ylabel("$v_4$ (component along the time $x4$)")
axes[1].set_title("boost in $(x1, x4)$: hyperbolas")
axes[1].legend(loc="upper center", bbox_to_anchor=(0.5, -0.14))
save_figure(fig, "orbits",
            ...)
```

The left picture draws the circle and a dot every 15 steps (`[::15]` takes every fifteenth row, that is every $\pi/4$); `set_aspect("equal")` gives both axes the same scale, so that a circle looks round. The right picture draws the two hyperbola branches and the two dotted **null lines** $v_4 = \pm v_1$, on which $v_1^2 - v_4^2 = 0$. In `05d_4_orbits.png` neither hyperbola crosses the null lines: a boost never turns a space-like vector into a time-like one.

In [11], which generators keep the form of B.

```
keep_B = [p for p in pairs if not (S[p].T @ B + B @ S[p]).any()]
break_B = [p for p in pairs if p not in keep_B]
rule_x4 = all(np.array_equal(S[("x4", b)].T @ B + B @ S[("x4", b)],
                             1j * (C @ gamma[b])) for b in COORDS if b != "x4")
say(f"generators with S^T B + B S = 0: {len(keep_B)}; the others: "
```

```
    + " ".join(f"({a},{b})" for a, b in break_B))
check_reproduces(len(keep_B) == 21 and all("x4" in p for p in break_B) and rule_x4
                 and recorded("wolfram", "S_preserves_B_only_off_x4"),
                 "S^dagger B + B S = 0 exactly for the 21 generators without x4; for "
                 "S^(x4 b) it equals i C gamma^b",
                 record=record_of("wolfram", "S_preserves_B_only_off_x4"))
```

`keep_B` lists the planes whose generator obeys $S^T B + BS = 0$ (S is real, so $S^T = S^\dagger$); `break_B` the others. `rule_x4` checks the formula $iC\gamma^b$ of Section 5.18 for the seven generators $S^{(x4)b}$. The printed line shows 21 planes that keep B and the seven planes with $x4$. (`"x4" in p` is true when the pair `p` contains the name `x4`.)

```
finite_C = max(np.max(np.abs(spin_transformation(a, b, 0.7).T @ C
                             @ spin_transformation(a, b, 0.7) - C)) for a, b in pairs)
finite_B = {p: np.max(np.abs(spin_transformation(*p, 0.7).T @ B
                             @ spin_transformation(*p, 0.7) - B)) for p in pairs}
check(finite_C < 1e-12 and all((finite_B[p] < 1e-12) == (p in keep_B) for p in pairs),
      "at theta = 0.7: R^T C R = C for all 28 planes; R^T B R = B exactly for the 21 "
      "planes without x4")
```

For finite transformations at $\theta = 0.7$ the cell computes the largest entry of $R^T C R - C$ over all 28 planes and of $R^T B R - B$ for each plane (`spin_transformation(*p, 0.7)` unpacks the pair `p` into the two arguments `a` and `b`). The check: the form of C is kept for all planes, that of B exactly for the 21 planes without $x4$.

In [12], the picture of the forms.

```
thetas = np.linspace(-3.0, 3.0, 241)
planes = [("x1", "x2"), ("x5", "x6"), ("x1", "x4"), ("x4", "x5")]
colors = ["#2a78d6", "#1baf7a", "#eb6834", "#4a3aa7"]
lines = ["-", "--", "-", "-."]
change_B = {p: [np.max(np.abs(spin_transformation(*p, th).T @ B
                              @ spin_transformation(*p, th) - B)) for th in thetas]
            for p in planes}
change_C = max(np.max(np.abs(spin_transformation(*p, th).T @ C
                             @ spin_transformation(*p, th) - C))
               for p in planes for th in thetas)
shown = "below 1e-12" if change_C < 1e-12 else f"{change_C:.2e}"
say(f"largest change of the form of C over the four planes and all angles: {shown}")
```

For four planes (two rotations without $x4$, a boost and a rotation with $x4$) and 241 values of θ the cell computes how much the form of B changes; for the form of C only the largest change over everything is kept and printed (below 10^{-12}; the cell prints the words instead of a number because the last digits of rounding differ between computers).

```
fig, ax = plt.subplots(figsize=(8.0, 4.4))
for p, color, line in zip(planes, colors, lines):
    name = "rotation" if kind[p] == 1 else "boost"
    ax.plot(thetas, change_B[p], color=color, linestyle=line, linewidth=2,
            label=f"form of $B$, {name} in $({p[0]}, {p[1]})$")
```

```
ax.plot(thetas, np.zeros_like(thetas), ":", color="black", linewidth=2,
        label="form of $C$, all four planes")
ax.set_xlabel(r"angle or rapidity $\theta$")
ax.set_ylabel("largest entry of the change")
ax.set_title(r"$R^T C R - C$ is always 0; $R^T B R - B$ only away from $x4$")
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.15), ncol=2)
save_figure(fig, "invariant_forms",
            ...)
```

One curve per plane for the form of B, and a dotted line at zero for the form of C. In `05d_5_in variant_forms.png` the two rotations without $x4$ lie on the horizontal axis (no change), while the boost in $(x1, x4)$ and the rotation in $(x4, x5)$ rise away from $\theta = 0$.

In [13], reflections.

```
def gamma_of(v):
    return sum(v[i] * gamma[x].astype(float) for i, x in enumerate(COORDS))

def metric_product(u, v):
    return float(u @ ETA_MATRIX @ v)

def reflection(u):
    return np.eye(8) - 2.0 * np.outer(u, u @ ETA_MATRIX) / metric_product(u, u)
```

`gamma_of(v)` is $\gamma(v) = \sum_a v_a \gamma^a$; `metric_product(u, v)` is $\eta(u, v) = u^T \eta v$; `reflection(u)` is the 8×8 matrix of R_u: since $R_u v = v - 2u\,(u^T \eta v)/\eta(u, u)$, its matrix is $1 - 2\,u\,(\eta u)^T/\eta(u, u)$, and `np.outer(u, u @ ETA_MATRIX)` is the column u times the row $u^T \eta$.

```
e = np.eye(8)  # e[i] is the unit vector along COORDS[i]
tilted = np.cosh(0.5) * e[1] + np.sinh(0.5) * e[4]  # in the plane (x1, x4)
v = np.arange(1, 9) / 10.0
reflections_ok = True
for u in (e[1], e[4], tilted):  # e_x1, e_x4 and the tilted vector
    gu = gamma_of(u)
    left = -gu @ gamma_of(v) @ np.linalg.inv(gu)
    Ru = reflection(u)
    reflections_ok &= (np.allclose(left, gamma_of(Ru @ v), atol=1e-12)
                       and abs(np.linalg.det(Ru) + 1.0) < 1e-12
                       and np.allclose(Ru.T @ ETA_MATRIX @ Ru, ETA_MATRIX))
    say(f"eta(u, u) = {metric_product(u, u):+.6f}: reflection checked")
check(reflections_ok,
      "-gamma(u) gamma(v) gamma(u)^-1 = gamma(R_u v); det R_u = -1; R_u keeps eta")
```

Three unit vectors are tested: e_{x1} (space-like), e_{x4} (time-like) and the tilted $\cosh(0.5)\,e_{x1} + \sinh(0.5)\,e_{x4}$ (with $\eta = \cosh^2 - \sinh^2 = 1$), each with the fixed vector $v = (0.1, 0.2, \ldots, 0.8)$. For each, the key identity of Section 5.12, $\det R_u = -1$ and $R_u^T \eta R_u = \eta$ are checked, and $\eta(u, u)$ is printed: $+1$, -1, $+1$.

In [14], the spinor norm, $\Lambda(\Gamma)$ and the double cover.

```
elements = [("gamma^(x1)", [e[1]]), ("gamma^(x4)", [e[4]]),
            ("gamma^(x1) gamma^(x4)", [e[1], e[4]]),
            ("gamma(tilted) gamma^(x5)", [tilted, e[5]]),
            ("Gamma", [e[i] for i in range(8)])]
norm_ok = True
for name, factors in elements:
    g = np.eye(16)
    for u in factors:
        g = g @ gamma_of(u)
    k = len(factors)
    N = int(round(np.prod([metric_product(u, u) for u in factors])))
    predicted = (-1) ** k * N
    norm_ok &= np.allclose(g.T @ C @ g, predicted * C, atol=1e-12)
    say(f"{name:26} k = {k}, N(g) = {N:+d}: g^T C g = {predicted:+d} C")
check(norm_ok, "g^T C g = (-1)^k N(g) C for all five elements")
```

Five elements of Pin(4,4) are given by their unit-vector factors (for Γ: e_{x0} followed by $e_{x1}, \ldots, e_{x7}$). For each, the product g, the number of factors k and the spinor norm $N(g)$ (the product of the $\eta(u,u)$, rounded to a whole number) are computed, and $g^T C g$ is compared with $(-1)^k N(g)\, C$. The printed table shows in particular $g^T C g = -C$ for $\gamma^{(x1)}\gamma^{(x4)}$ and for $\gamma(\text{tilted})\gamma^{(x5)}$: two even elements that are not products of exponentials.

```
check(np.allclose(vector_matrix(Gamma.astype(float)), -np.eye(8), atol=1e-12),
      "Gamma moves every direction to its opposite: Lambda(Gamma) = -1 (det +1)")
cover_ok = all(
    np.allclose(spin_transformation("x1", "x2", th + 2 * np.pi),
                -spin_transformation("x1", "x2", th), atol=1e-12)
    and np.allclose(vector_matrix(spin_transformation("x1", "x2", th + 2 * np.pi)),
                    vector_matrix(spin_transformation("x1", "x2", th)), atol=1e-12)
    for th in np.linspace(0.0, 2 * np.pi, 7))
check(cover_ok, "R(theta + 2 pi) = -R(theta), and both move the vectors in the "
      "same way: two spinor matrices for every vector matrix")
```

Γ is even, and its vector matrix is -1_8: by (X2), $\Gamma\gamma^c\Gamma^{-1} = -\gamma^c$. Then, for seven angles, $R(\theta + 2\pi) = -R(\theta)$ and the two have the same vector matrix.

In [15], the determinants of the gammas.

```
import sympy as sp  # exact algebra

determinants = {x: sp.Matrix(gamma[x].tolist()).det() for x in COORDS}
say("det gamma^(x) = " + ", ".join(f"{x}: {determinants[x]}" for x in COORDS))
check(all(d == 1 for d in determinants.values()),
      "every gamma matrix has determinant +1 as a 16 x 16 matrix")
```

sympy computes the eight determinants exactly. The printed line shows 1 for every direction, as Rule 6 predicts.

In [16], four vector matrices as pictures.

```
pictures = [(vector_matrix(spin_transformation("x1", "x2", np.pi / 3)),
             r"rotation, $\theta = \pi/3$, $(x1, x2)$"),
```

```
            (vector_matrix(spin_transformation("x1", "x4", 1.0)),
             r"boost, $\theta = 1$, $(x1, x4)$"),
            (reflection(e[1]), r"reflection $R_u$, $u = e_{x1}$"),
            (vector_matrix(Gamma.astype(float)), r"$\Lambda(\Gamma) = -1_8$")]
fig, axes = plt.subplots(1, 4, figsize=(14.0, 4.0))
for k, (ax, (matrix, title)) in enumerate(zip(axes, pictures)):
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1.6, vmax=1.6)
    for i in range(8):
        for j in range(8):
            if abs(matrix[i, j]) > 1e-12:  # write the nonzero entries
                ax.text(j, i, f"{matrix[i, j]:.2f}", ha="center", va="center",
                        fontsize=6)
    ax.set_xticks(range(8), COORDS, fontsize=7)
    ax.set_yticks(range(8), COORDS, fontsize=7)
    ax.set_title(title, fontsize=9)
    ax.grid(False)
fig.colorbar(image, ax=axes, shrink=0.8, label="matrix entry")
save_figure(fig, "vector_matrices",
            ...)
```

Four 8×8 matrices are drawn with the colour scale from -1.6 to 1.6 (a boost has entries $\cosh 1 \approx 1.54$), and each nonzero entry is written in its square with two decimals (`:.2f`). In `05d_6_vector_matrices.png` the rotation has 0.50 and ±0.87 (cos and sin of $\pi/3$) in the $(x1, x2)$ block, the boost 1.54 and -1.18 ($\cosh 1$ and $-\sinh 1$) in the $(x1, x4)$ block, the reflection one -1 at $x1$, and $\Lambda(\Gamma)$ is -1 on the whole diagonal.

In [17], the last check.

```
FIGURES = ["05d_1_plane_types.png", "05d_2_half_angles.png",
           "05d_3_rotation_matrices.png", "05d_4_orbits.png",
           "05d_5_invariant_forms.png", "05d_6_vector_matrices.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the six figure files of notebook 05d exist")
all_checks_passed()
```

The six figure files must exist, and the last line reads ALL 20 CHECKS PASSED (notebook 05d): one in In [2], three in In [3], one in In [4], In [5] and In [6] each, two in In [7], one each in In [8], In [9] and In [10], two in In [11], one in In [13], three in In [14], one in In [15] and one in In [17]. Six of them (In [2], the three of In [3], In [4] and the first of In [11]) reproduce recorded checks; the other fourteen are the notebook's own computations.

5.23 What do the scaled commutators generate?

The 28 scaled commutators $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b]$ are called the generators. It is tempting to say that they generate Pin(4,4). This section answers exactly what they generate, and the answer is: **not all of Pin(4,4), and not even all of Spin(4,4)**. The products of their exponentials form the piece of Pin(4,4) that is joined to 1, written $\mathrm{Spin}_0(4,4)$; Pin(4,4) consists of four such pieces; and the exponentials together with the two gammas $\gamma^{(x0)}$ and $\gamma^{(x4)}$ generate all of Pin(4,4). The proof has ten steps, (A) to (J); Notebook 05f checks each of them on the matrices.

(A) The matrices by which the generators move the directions. The vector rule of Section 5.12 can be written $[S^{ab},\gamma^c]=\sum_d M^{ab}_{dc}\gamma^d$ with the 8×8 matrix

$$M^{ab}_{dc}=\eta^{bc}\delta_{da}-\eta^{ac}\delta_{db},$$

where δ_{da} is 1 for $d=a$ and 0 otherwise (insert it: the sum over d picks $\eta^{bc}\gamma^a-\eta^{ac}\gamma^b$). For $a\neq b$ exactly two entries are nonzero: in row a, column b the entry $\eta^{bb}=\eta_{bb}$ (take $c=b$, $d=a$), and in row b, column a the entry $-\eta_{aa}$ (take $c=a$, $d=b$).

(B) A basis of so(4,4). The Lie algebra **so(4,4)** is the set of real 8×8 matrices X with $X^T\eta+\eta X=0$ (the infinitesimal form of $\Lambda^T\eta\Lambda=\eta$). Since $(\eta X)^T=X^T\eta$, the condition says that ηX is antisymmetric. An antisymmetric 8×8 matrix is fixed by its $8\cdot 7/2=28$ entries above the diagonal, so so(4,4) has dimension 28. For M^{ab} the matrix ηM^{ab} has the entry $\eta_{aa}\eta_{bb}$ in row a, column b and $-\eta_{bb}\eta_{aa}$ in row b, column a: it is antisymmetric, so every M^{ab} lies in so(4,4). The 28 matrices M^{ab} with a before b have their nonzero entries in 28 different pairs of places, so they are independent: they are a **basis** of so(4,4).

(C) Commutators go to commutators. Multiplying out shows the **Jacobi identity** $[[X,Y],Z]=[X,[Y,Z]]-[Y,[X,Z]]$ for any three matrices (both sides are $XYZ-YXZ-ZXY+ZYX$). Let $[S_1,\gamma^c]=\sum_d(M_1)_{dc}\gamma^d$ and $[S_2,\gamma^c]=\sum_d(M_2)_{dc}\gamma^d$. Then

$$[S_1,[S_2,\gamma^c]]=\sum_d(M_2)_{dc}[S_1,\gamma^d]=\sum_{d,e}(M_1)_{ed}(M_2)_{dc}\gamma^e=\sum_e(M_1M_2)_{ec}\gamma^e,$$

and the Jacobi identity gives $[[S_1,S_2],\gamma^c]=\sum_e([M_1,M_2])_{ec}\gamma^e$: **the matrix of a commutator is the commutator of the matrices.** Together with (B) and the so(4,4) rules of Section 5.18, the 28 independent S^{ab} and the 28 matrices M^{ab} have the same commutation table: the S^{ab} span an exact copy of so(4,4). (The S^{ab} are independent because they are one half times 28 different products of two gammas, which are independent by Section 5.13.)

(D) Every exponential is a product of two unit vectors. For a rotation ($\eta_{aa}\eta_{bb}=+1$), $\exp(\theta S^{ab})=\cos\frac{\theta}{2}\,1+\sin\frac{\theta}{2}\,\gamma^a\gamma^b$ (Section 5.18). Because $\gamma^a\gamma^a=\eta_{aa}1$ and $\eta_{aa}^2=1$,

$$\gamma^a\big(\eta_{aa}\cos\tfrac{\theta}{2}\,\gamma^a+\sin\tfrac{\theta}{2}\,\gamma^b\big)=\cos\tfrac{\theta}{2}\,1+\sin\tfrac{\theta}{2}\,\gamma^a\gamma^b.$$

So $\exp(\theta S^{ab})=\gamma^a\gamma(u)$ with $u=\eta_{aa}\cos\frac{\theta}{2}\,e_a+\sin\frac{\theta}{2}\,e_b$, and $\eta(u,u)=\eta_{aa}\cos^2\frac{\theta}{2}+\eta_{bb}\sin^2\frac{\theta}{2}=\eta_{aa}$ (since $\eta_{bb}=\eta_{aa}$ for a rotation). For a boost the same steps with cosh and sinh give $u=\eta_{aa}\cosh\frac{\theta}{2}\,e_a+\sinh\frac{\theta}{2}\,e_b$ and $\eta(u,u)=\eta_{aa}(\cosh^2\frac{\theta}{2}-\sinh^2\frac{\theta}{2})=\eta_{aa}$, since $\eta_{bb}=-\eta_{aa}$. Both γ^a and $\gamma(u)$ are unit vectors: **every exponential lies in Spin(4,4)**, and so does every product of exponentials.

(E) How an exponential moves the directions. Put $R(\theta)=\exp(\theta S)$ for one generator $S=S^{ab}$, and $F_c(\theta)=R\gamma^cR^{-1}$. Differentiating the power series term by term gives $dR/d\theta=SR=RS$, and $d(R^{-1})/d\theta=-SR^{-1}$ (since $R^{-1}=\exp(-\theta S)$). By the product rule of differentiation,

$$\frac{dF_c}{d\theta}=SR\gamma^cR^{-1}-R\gamma^cSR^{-1}=R\,[S,\gamma^c]\,R^{-1}=\sum_d M_{dc}F_d.$$

Writing $F_c=\sum_e\Lambda_{ec}(\theta)\gamma^e$, this says $d\Lambda/d\theta=\Lambda M$ with $\Lambda(0)=1$, whose solution is the matrix

exponential $\Lambda(\theta) = \exp(\theta M)$ (it solves the equation, because $d\exp(\theta M)/d\theta = \exp(\theta M)M$, and a linear equation of this kind has only one solution with a given starting value, a fact of the theory of differential equations quoted here). From the two entries of $M = M^{ab}$: $Me_a = -\eta_{aa}e_b$ and $Me_b = \eta_{bb}e_a$, so $MMe_a = -\eta_{aa}\eta_{bb}e_a$. Summing the power series as in Section 5.18:

$$\Lambda e_a = \cos\theta\, e_a - \eta_{aa}\sin\theta\, e_b \quad \text{(rotation)}, \qquad \Lambda e_a = \cosh\theta\, e_a - \eta_{aa}\sinh\theta\, e_b \quad \text{(boost)}.$$

(F) The forbidden band. Order the directions as $x0, x1, x2, x3$ (space-like) and then $x4, x5, x6, x7$ (time-like), and cut a vector matrix into four 4×4 blocks,

$$\Lambda = \begin{pmatrix} A & B' \\ C' & D \end{pmatrix}.$$

A is the **space block** and D the **time block** (the primes distinguish the other two blocks from the matrices B and C). In this order $\eta = \mathrm{diag}(1_4, -1_4)$, and multiplying out the blocks of $\Lambda^T\eta\Lambda = \eta$ gives, in the top-left and bottom-right places,

$$A^TA - C'^TC' = 1_4, \qquad D^TD - B'^TB' = 1_4.$$

For every column w of four numbers the first equation gives $|Aw|^2 = w^TA^TAw = |w|^2 + |C'w|^2 \geq |w|^2$, where $|w|^2 = w^Tw$ is the squared length. So every eigenvalue of the symmetric matrix A^TA is at least 1 (take w an eigenvector of length 1), and $(\det A)^2 = \det(A^TA)$, the product of these eigenvalues, is at least 1. **So** $\det A$ **is never between** -1 **and** 1; the same holds for $\det D$. This holds for every matrix of O(4,4).

(G) Products of exponentials stay above the band. Let $h = \exp(\theta_1 S_1)\cdots\exp(\theta_n S_n)$ be a product of exponentials, and $h(t) = \exp(t\theta_1 S_1)\cdots\exp(t\theta_n S_n)$ for $0 \leq t \leq 1$: a path from $h(0) = 1$ to $h(1) = h$. The entries of $\Lambda(h(t))$ are sums of products of cos, sin, cosh and sinh of multiples of t, so $\det A(t)$ is a continuous function of t. It starts at $\det 1_4 = 1$ and never enters the band $(-1, 1)$; by the intermediate value theorem (a continuous function that takes a value below -1 and one above 1 also takes every value between) it can never become negative. So $\det A \geq 1$ along the whole path, and in the same way $\det D \geq 1$. **Every product of exponentials has the sign pattern** $(+,+)$, where the **sign pattern** of g is the pair (sign of $\det A$, sign of $\det D$).

(H) Four pieces. $\Lambda(\gamma^{(x0)}) = R_{e_{x0}}$ reverses only the direction $x0$: its space block has determinant -1 and its time block $+1$, pattern $(-,+)$. $\Lambda(\gamma^{(x4)})$ reverses only $x4$: pattern $(+,-)$. $\Lambda(\gamma^{(x0)}\gamma^{(x4)})$ reverses both: $(-,-)$. For a product of exponentials h and w one of these, $\Lambda(hw) = \Lambda(h)\Lambda(w)$ (Section 5.12), and $\Lambda(w)$ is a diagonal matrix of signs: multiplying by it from the right only changes the signs of some columns of $\Lambda(h)$, so the space block of hw is A times a diagonal matrix of signs and hw has the pattern of w. Four different patterns: the four sets

$$\mathrm{Spin}_0, \quad \mathrm{Spin}_0\,\gamma^{(x0)}, \quad \mathrm{Spin}_0\,\gamma^{(x4)}, \quad \mathrm{Spin}_0\,\gamma^{(x0)}\gamma^{(x4)}$$

have no element in common, where $\mathrm{Spin}_0 = \mathrm{Spin}_0(4,4)$ is the group of all products of exponentials and $\mathrm{Spin}_0\,w$ the set of the products hw. In particular $\gamma^{(x0)}\gamma^{(x4)}$ **lies in Spin(4,4) but is not a product of exponentials**, in agreement with its spinor norm (Section 5.18).

(I) Every unit vector is a turned $\gamma^{(x0)}$ or $\gamma^{(x4)}$. Let v be a space-like unit vector, with space part σ (its components along $x0, x1, x2, x3$) and time part τ (along $x4, \ldots, x7$), so that $|\sigma|^2 - |\tau|^2 = 1$. Three stages carry e_{x0} to v:

- a boost in the plane $(x0, x4)$ carries e_{x0} to $|\sigma|\, e_{x0} + |\tau|\, e_{x4}$ (by (E), choose $\sinh\theta = -|\tau|$; then $\cosh\theta = \sqrt{1+|\tau|^2} = |\sigma|$);
- three rotations in the planes $(x4, x5)$, $(x4, x6)$, $(x4, x7)$ turn e_{x4} into $\tau/|\tau|$ and do not touch $x0$, giving $|\sigma|\, e_{x0} + \tau$;
- three rotations in the planes $(x0, x1)$, $(x0, x2)$, $(x0, x3)$ turn e_{x0} into $\sigma/|\sigma|$ and do not touch the time part, giving $\sigma + \tau = v$.

Each rotation stage turns the axis vector step by step: the first rotation puts the right component on the first other direction and keeps the rest of the length on the axis, the second does the same for the next direction, and the last leaves exactly the axis component of the target. The angles follow from (E). With h the product of these at most seven exponentials, $\Lambda(h)e_{x0} = v$, and since h is even,

$$h\gamma^{(x0)}h^{-1} = \sum_d \Lambda(h)_{d,x0}\,\gamma^d = \gamma(\Lambda(h)e_{x0}) = \gamma(v).$$

A time-like unit vector v has $|\tau|^2 - |\sigma|^2 = 1$. Three stages carry e_{x4} to v; compared with the space-like case, the boost has $\cosh\theta = |\tau|$ instead of $|\sigma|$, and the two rotation stages exchange their places:

- a boost in the plane $(x4, x0)$ carries e_{x4} to $|\tau|\, e_{x4} + |\sigma|\, e_{x0}$ (by (E) with $a = x4$ and $\eta_{aa} = -1$, $\Lambda e_{x4} = \cosh\theta\, e_{x4} + \sinh\theta\, e_{x0}$; choose $\sinh\theta = |\sigma|$; then $\cosh\theta = \sqrt{1+|\sigma|^2} = |\tau|$);
- three rotations in the planes $(x0, x1)$, $(x0, x2)$, $(x0, x3)$ turn e_{x0} into $\sigma/|\sigma|$ and do not touch $x4$, giving $|\tau|\, e_{x4} + \sigma$;
- three rotations in the planes $(x4, x5)$, $(x4, x6)$, $(x4, x7)$ turn e_{x4} into $\tau/|\tau|$ and do not touch the space part, giving $\sigma + \tau = v$.

With h the product of these at most seven exponentials, $\Lambda(h)e_{x4} = v$, and, since h is again even, the same final step with $x4$ in place of $x0$ gives

$$h\gamma^{(x4)}h^{-1} = \sum_d \Lambda(h)_{d,x4}\,\gamma^d = \gamma(\Lambda(h)e_{x4}) = \gamma(v).$$

In both cases, when the boost puts nothing on the other axis ($\tau = 0$ for a space-like v, $\sigma = 0$ for a time-like v), its angle is $\theta = 0$ and the middle stage is left out.

(J) Moving the gammas to the right. Moving γ^e through $\gamma^a\gamma^b$ costs $(-1)^2 = +1$ when e is neither a nor b, and -1 when e is one of them (Rule 1). So $\gamma^e S^{ab}(\gamma^e)^{-1} = s\, S^{ab}$ with that sign s, and, term by term in the power series,

$$\gamma^e \exp(\theta S^{ab}) = \exp(s\theta S^{ab})\,\gamma^e.$$

Now take any element $g = \gamma(v_1)\cdots\gamma(v_k)$ of Pin(4,4). Write each factor as in (I), $\gamma(v_j) = h_j\gamma^{e_j}h_j^{-1}$ with $e_j = x0$ or $x4$. Move every gamma to the right end with the rule just proved: what remains on the left is a product of exponentials, and on the right a product of gammas $\gamma^{(x0)}$ and $\gamma^{(x4)}$. With $\gamma^{(x0)}\gamma^{(x0)} = 1$, $\gamma^{(x4)}\gamma^{(x4)} = -1$ and $\gamma^{(x4)}\gamma^{(x0)} = -\gamma^{(x0)}\gamma^{(x4)}$, that product is $\pm$ one of 1, $\gamma^{(x0)}$, $\gamma^{(x4)}$, $\gamma^{(x0)}\gamma^{(x4)}$, and a sign -1 is itself the product of exponentials $\exp(2\pi S^{(x1)(x2)}) = -1$ (Section 5.18).

The answer. By (D) the exponentials lie in Pin(4,4), and $\gamma^{(x0)}$ and $\gamma^{(x4)}$ do by definition; by (I) and (J) every element of Pin(4,4) is a product of exponentials times one of the four words; by (G) and (H) the four pieces are different. So

$$\mathrm{Pin}(4,4) = \mathrm{Spin}_0 \cup \mathrm{Spin}_0\,\gamma^{(x0)} \cup \mathrm{Spin}_0\,\gamma^{(x4)} \cup \mathrm{Spin}_0\,\gamma^{(x0)}\gamma^{(x4)},$$

four pieces with no element in common, and Spin(4,4), the even elements, is the union of the first and the last piece. **The exponentials of the scaled commutators generate exactly $\mathrm{Spin}_0(4,4)$; together with $\gamma^{(x0)}$ and $\gamma^{(x4)}$ they generate all of Pin(4,4).** It is not correct to say that the scaled commutators alone generate Pin(4,4). Nothing in the representation statements of Section 5.13 changes: irreducibility under Pin(4,4) and the two inequivalent halves already hold for the smaller groups (Section 5.13).

What the group elements span. For a rotation, $\exp(\pi S^{ab}) = \gamma^a\gamma^b$ ($\cos\frac{\pi}{2} = 0$, $\sin\frac{\pi}{2} = 1$); for a boost, $(\exp(\theta S^{ab}) - \exp(-\theta S^{ab}))/(2\sinh\frac{\theta}{2}) = \gamma^a\gamma^b$. So the span of $\mathrm{Spin}_0(4,4)$ contains every product of two different gammas, and, because the span of a group contains the products of its members, every even product of different gammas: all 128 of them. Every element is even, so the span is exactly these 128 dimensions, the block-diagonal matrices. Adding one gamma adds the odd products: the span of Pin(4,4) is all 256 dimensions.

statement	**status**	**where it is verified**
the 28 S^{ab} are independent (rank 28) and span a copy of so(4,4)	PROVED; rank COMPUTED exactly	`python-algebra.json`, checks `S_definition`, `S_vector_action` and `S_lorentz_algebra`; Notebook 05f (rank 28, dimension of so(4,4) 28, the 784 commutators of the M^{ab})
(D) and (E): $\exp(\theta S^{ab}) = \gamma^a\gamma(u)$; $\Lambda = \exp(\theta M^{ab})$	PROVED above; COMPUTED (to 10^{-10} and 10^{-12})	Notebook 05f, its own computation
(F) to (H): the forbidden band, the sign pattern $(+,+)$ of $\mathrm{Spin}_0(4,4)$, the four pieces	PROVED above; COMPUTED on 200 and 240 random elements and along ten paths	Notebook 05f, its own computation
(I) and (J): every element of Pin(4,4) is in one of the four pieces	PROVED above; COMPUTED on 40 unit vectors and 12 elements	Notebook 05f, its own computation
the spans: 128 for $\mathrm{Spin}_0(4,4)$, 256 for Pin(4,4)	PROVED above; COMPUTED (singular values)	`python-algebra.json`, checks `even_products_span_M8_plus_M8` and `clifford_products_span_M16`; Notebook 05f

5.24 Example: Notebook 05f computes what the scaled commutators generate

Notebook 05f checks steps (A) to (J) one by one: the rank 28 of the generators, the 28 matrices M^{ab} and their commutators, the dimension 28 of so(4,4), the factorisation of every exponential into two unit vectors, the formula $\Lambda = \exp(\theta M)$, the block equations and the band on 200 random products of exponentials, the four sign patterns on 240 random elements, ten paths from 1 that never cross the band, the construction of (I) on 40 random unit vectors, the rule of (J), the decomposition of 12 random elements of Pin(4,4) into exponentials times one of four words, and the spans 128 and 256. All random numbers come from a generator with a fixed seed, so every run makes the same choices. It draws six figures and ends with ALL 24 CHECKS PASSED (notebook 05f).

5.25 How to run Notebook 05f

Step 1. What this notebook does and what it needs.

Notebook 05f (What the scaled commutators generate: Spin_0(4,4), and with two gammas all of Pin(4,4)) is the file `Revision/textbook/notebooks/05f_pin_generation.ipynb` of the repository Dirac_claude. It answers exactly the question whether the 28 scaled commutators S^ab = (1/4)(gamma^a gamma^b - gamma^b gamma^a) generate Pin(4,4). It checks that they are 28 independent matrices whose action on the eight directions is a basis of so(4,4) with the same commutators, writes every exponential exp(theta S^ab) as a product of two unit vectors, proves with the space and time blocks of the vector matrices that the products of exponentials form only the part Spin_0(4,4) of Pin(4,4) that is joined to 1, constructs for every unit vector v a product h of exponentials with gamma(v) = h gamma^(x0) h^-1 or h gamma^(x4) h^-1, and so writes every element of Pin(4,4) as a product of exponentials times one of 1, gamma^(x0), gamma^(x4) and gamma^(x0) gamma^(x4). Six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05f_pin_generation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05f_pin_generation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05f_pin_generation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/05f.captions.json`
- `Revision/textbook/figures/05f_1_generator_matrices.png`
- `Revision/textbook/figures/05f_2_two_unit_vectors.png`
- `Revision/textbook/figures/05f_3_four_pieces.png`
- `Revision/textbook/figures/05f_4_paths_and_band.png`
- `Revision/textbook/figures/05f_5_carrying_vectors.png`
- `Revision/textbook/figures/05f_6_span_ranks.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05f exist
ALL 24 CHECKS PASSED (notebook 05f)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/05f_pin_generation.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05f_pin_generation.ipynb
python -m nbconvert --execute --inplace 05f_pin_generation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

5.26 Notebook 05f: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05f_pin_generation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The 28 **scaled commutators** $S^{ab} = \tfrac14[\gamma^a, \gamma^b] =
\tfrac14(\gamma^a\gamma^b - \gamma^b\gamma^a)$ of the author's eight real
$16 \times 16$ gamma matrices are called the *generators*. Do they generate the
group Pin(4,4)? This notebook gives the exact answer, with every step written out
and checked on the matrices:

1. the $S^{ab}$ are 28 independent matrices; the way each of them moves the eight
   coordinate directions is an $8 \times 8$ matrix $M^{ab}$, and the 28 matrices
   $M^{ab}$ form a basis of the Lie algebra so(4,4) and have the same commutators
   as the $S^{ab}$;
2. every exponential $\exp(\theta S^{ab})$ is a product $\gamma^a\gamma(u)$ of two
   unit vectors, so it lies in Spin(4,4), the even part of Pin(4,4);
3. the products of exponentials form a group, written $\mathrm{Spin}_0(4,4)$, whose
   elements are all joined to $1$ by a path. It is **not** all of Pin(4,4), and not
   even all of Spin(4,4): the space block and the time block of the matrix by which
   such an element moves the directions both have determinant at least $1$, while
   $\gamma^{(x0)}$, $\gamma^{(x4)}$ and $\gamma^{(x0)}\gamma^{(x4)}$ give the other
   three combinations of signs;
4. every unit vector $\gamma(v)$ equals $h\gamma^{(x0)}h^{-1}$ or
   $h\gamma^{(x4)}h^{-1}$ with $h$ a product of at most seven exponentials (an
```

```
   explicit construction, tested on 40 random unit vectors);
5. therefore every element of Pin(4,4) is a product of exponentials times exactly
   one of $1$, $\gamma^{(x0)}$, $\gamma^{(x4)}$, $\gamma^{(x0)}\gamma^{(x4)}$
   (tested on 12 random elements): Pin(4,4) consists of four pieces, and it is
   generated by the exponentials of the scaled commutators **together with the two
   gammas** $\gamma^{(x0)}$ and $\gamma^{(x4)}$;
6. the elements of $\mathrm{Spin}_0(4,4)$ span the 128 block-diagonal matrices and
   those of Pin(4,4) all 256 matrices, the ranks recorded in the Revision record.

Every check that repeats a recorded check prints the record file and the check
name. Six teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 05f (What the scaled commutators generate: Spin_0(4,4), and with two gammas all
of Pin(4,4)) is the file ‘Revision/textbook/notebooks/05f_pin_generation.ipynb‘ of the
repository Dirac_claude. It answers exactly the question whether the 28 scaled
commutators S^ab = (1/4)(gamma^a gamma^b - gamma^b gamma^a) generate Pin(4,4). It checks
that they are 28 independent matrices whose action on the eight directions is a basis of
so(4,4) with the same commutators, writes every exponential exp(theta S^ab) as a product
of two unit vectors, proves with the space and time blocks of the vector matrices that
the products of exponentials form only the part Spin_0(4,4) of Pin(4,4) that is joined to
1, constructs for every unit vector v a product h of exponentials with gamma(v) = h
gamma^(x0) h^-1 or h gamma^(x4) h^-1, and so writes every element of Pin(4,4) as a
product of exponentials times one of 1, gamma^(x0), gamma^(x4) and gamma^(x0) gamma^(x4).
Six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):
```

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05f_pin_generation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05f_pin_generation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05f_pin_generation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05f.captions.json‘
- ‘Revision/textbook/figures/05f_1_generator_matrices.png‘
- ‘Revision/textbook/figures/05f_2_two_unit_vectors.png‘
- ‘Revision/textbook/figures/05f_3_four_pieces.png‘
- ‘Revision/textbook/figures/05f_4_paths_and_band.png‘
- ‘Revision/textbook/figures/05f_5_carrying_vectors.png‘
- ‘Revision/textbook/figures/05f_6_span_ranks.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 05f exist
ALL 24 CHECKS PASSED (notebook 05f)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/05f_pin_generation.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 05f_pin_generation.ipynb
  python -m nbconvert --execute --inplace 05f_pin_generation.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers

‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 05f (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05f (What the scaled commutators generate: Spin_0(4,4), and with two gammas
# all of Pin(4,4)) is the file Revision/textbook/notebooks/05f_pin_generation.ipynb of
# the repository Dirac_claude. It answers exactly the question whether the 28 scaled
# commutators S^ab = (1/4)(gamma^a gamma^b - gamma^b gamma^a) generate Pin(4,4). It
# checks that they are 28 independent matrices whose action on the eight directions is a
# basis of so(4,4) with the same commutators, writes every exponential exp(theta S^ab) as
# a product of two unit vectors, proves with the space and time blocks of the vector
# matrices that the products of exponentials form only the part Spin_0(4,4) of Pin(4,4)
# that is joined to 1, constructs for every unit vector v a product h of exponentials
# with gamma(v) = h gamma^(x0) h^-1 or h gamma^(x4) h^-1, and so writes every element of
# Pin(4,4) as a product of exponentials times one of 1, gamma^(x0), gamma^(x4) and
# gamma^(x0) gamma^(x4). Six teaching plots. It needs a computer with Windows 11, macOS
# or Linux, an internet connection for the installation, the program Git, and Python 3.12
# or newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
```

```
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
```

```
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05f_pin_generation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
```

```
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05f_pin_generation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 05f_pin_generation.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/05f.captions.json
# - Revision/textbook/figures/05f_1_generator_matrices.png
# - Revision/textbook/figures/05f_2_two_unit_vectors.png
# - Revision/textbook/figures/05f_3_four_pieces.png
# - Revision/textbook/figures/05f_4_paths_and_band.png
# - Revision/textbook/figures/05f_5_carrying_vectors.png
# - Revision/textbook/figures/05f_6_span_ranks.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the six figure files of notebook 05f exist
#     ALL 24 CHECKS PASSED (notebook 05f)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05f_pin_generation.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
```

```
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05f_pin_generation.ipynb
#     python -m nbconvert --execute --inplace 05f_pin_generation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra: the notebook was
#   opened outside the repository, or the repository is incomplete; clone the repository
#   again and open the notebook from its folder Revision/textbook/notebooks.

## 3. The words used in this notebook

- **Commutator** $[X, Y] = XY - YX$ of two matrices.
- **Unit vector**: eight numbers $v = (v_{x0}, \dots, v_{x7})$ with metric product
```

```
  $\eta(v, v) = \sum_a \eta_{aa} v_a^2 = +1$ (*space-like*) or $-1$ (*time-like*);
  $\eta_{aa} = +1$ for $x0, x1, x2, x3$ and $-1$ for $x4, x5, x6, x7$. The basic
  unit vectors are $e_{x0}, \dots, e_{x7}$ (one entry 1, the others 0).
- $\gamma(v) = \sum_a v_a\gamma^a$; it obeys $\gamma(v)\gamma(v) = \eta(v, v)\,1$.
- **Pin(4,4)**: all products $\gamma(u_1)\gamma(u_2)\cdots\gamma(u_k)$ of unit
  vectors ($k = 0, 1, 2, \dots$). **Spin(4,4)**: those with an even number $k$ of
  factors (the *even* elements; the others are *odd*).
- **Exponential** of a matrix: $\exp(X) = 1 + X + X^2/2 + X^3/6 + \dots =
  \sum_{k \ge 0} X^k/k!$.
- **$\mathrm{Spin}_0(4,4)$**: all products of exponentials $\exp(\theta S^{ab})$.
  It is a group: the product of two products is a product, and the inverse of
  $\exp(\theta S^{ab})$ is $\exp(-\theta S^{ab})$.
- **Generated by**: the group *generated by* some matrices is the set of all
  products of these matrices and their inverses.
- **O(4,4)**: the real $8 \times 8$ matrices $\Lambda$ with $\Lambda^T\eta\Lambda =
  \eta$ (they keep the metric product); **SO(4,4)**: those with determinant $+1$.
- **so(4,4)**: the real $8 \times 8$ matrices $X$ with $X^T\eta + \eta X = 0$ (the
  *Lie algebra* of O(4,4)).
- **Rotation, boost**: the exponential $\exp(\theta S^{ab})$ of a plane of two
  directions of the same kind (rotation, angle $\theta$) or of different kinds
  (boost, rapidity $\theta$).
- **Vector matrix** $\Lambda(g)$: the $8 \times 8$ matrix with
  $\alpha(g)\gamma^c g^{-1} = \sum_d \Lambda_{dc}\gamma^d$, where $\alpha(g) = g$
  for an even and $-g$ for an odd $g$ (the *twisted* action).
- **Reflection** $R_u$ along a unit vector $u$: $R_u v = v - 2\eta(u, v)u/
  \eta(u, u)$; it reverses $u$ and keeps every direction orthogonal to $u$.
- **Space block, time block**: with the directions ordered $x0, x1, x2, x3$ (space)
  and then $x4, x5, x6, x7$ (time), a vector matrix splits into four $4 \times 4$
  blocks $\Lambda = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$; $A$ is the
  *space block* and $D$ the *time block*.
- **Sign pattern** of $g$: the pair $(\mathrm{sign}\det A, \mathrm{sign}\det D)$.
- **Rank** of a list of matrices: the number of independent ones among them;
  **span**: all their combinations.
```

Text cell:

```
## 4. The physical and mathematical situation

**(A) The generators move the directions.** For $a \neq b$ the gammas anticommute,
so $S^{ab} = \tfrac12\gamma^a\gamma^b$. Using the Clifford relation
$\gamma^b\gamma^c = -\gamma^c\gamma^b + 2\eta^{bc}$ and then $\gamma^a\gamma^c =
-\gamma^c\gamma^a + 2\eta^{ac}$:

$$\gamma^a\gamma^b\gamma^c = -\gamma^a\gamma^c\gamma^b + 2\eta^{bc}\gamma^a
  = \gamma^c\gamma^a\gamma^b - 2\eta^{ac}\gamma^b + 2\eta^{bc}\gamma^a .$$

Halving gives the **vector rule** $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a -
\eta^{ac}\gamma^b = \sum_d M^{ab}_{dc}\gamma^d$ with the $8 \times 8$ matrix

$$M^{ab}_{dc} = \eta^{bc}\delta_{da} - \eta^{ac}\delta_{db}$$

($\delta_{da}$ is 1 for $d = a$ and 0 otherwise). Exactly two entries are
nonzero: row $a$, column $b$ holds $\eta_{bb}$; row $b$, column $a$ holds
```

$-\eta_{aa}$.

(B) so(4,4). $X^T\eta + \eta X = 0$ says that ηX is antisymmetric (because $(\eta X)^T = X^T\eta$). An antisymmetric 8×8 matrix is fixed by its $8 \cdot 7/2 = 28$ entries above the diagonal, so so(4,4) has dimension 28. For M^{ab}: $(\eta M^{ab})_{ab} = \eta_{aa}\eta_{bb}$ and $(\eta M^{ab})_{ba} = -\eta_{bb}\eta_{aa}$: antisymmetric, so M^{ab} lies in so(4,4).

(C) Commutators go to commutators. Expanding both sides shows the *Jacobi identity* $[[X, Y], Z] = [X, [Y, Z]] - [Y, [X, Z]]$ (each side is $XYZ - YXZ - ZXY + ZYX$). If $[S_1, \gamma^c] = \sum_d (M_1)_{dc}\gamma^d$ and the same for S_2, then $[S_1, [S_2, \gamma^c]] = \sum_d (M_2)_{dc}[S_1, \gamma^d] = \sum_e (M_1M_2)_{ec}\gamma^e$, and the Jacobi identity gives $[[S_1, S_2], \gamma^c] = \sum_e ([M_1, M_2])_{ec}\gamma^e$: the matrix of a commutator is the commutator of the matrices. So the 28 independent S^{ab} and the 28 independent M^{ab} (a basis of so(4,4)) have the same commutation table: the S^{ab} span an exact copy of so(4,4).

(D) Each exponential is a product of two unit vectors. For a rotation ($\eta_{aa}\eta_{bb} = +1$), $(\gamma^a\gamma^b)^2 = -1$ and the power series gives $\exp(\theta S^{ab}) = \cos\tfrac\theta2 + \sin\tfrac\theta2\,\gamma^a\gamma^b$; for a boost, $(\gamma^a\gamma^b)^2 = +1$ and $\exp(\theta S^{ab}) = \cosh\tfrac\theta2 + \sinh\tfrac\theta2\,\gamma^a\gamma^b$. Because $\gamma^a\gamma^a = \eta_{aa}$ and $\eta_{aa}^2 = 1$,

$$\gamma^a\big(\eta_{aa}\cos\tfrac\theta2\,\gamma^a + \sin\tfrac\theta2\,
  \gamma^b\big) = \cos\tfrac\theta2 + \sin\tfrac\theta2\,\gamma^a\gamma^b ,$$

so $\exp(\theta S^{ab}) = \gamma^a\gamma(u)$ with $u = \eta_{aa}\cos\tfrac\theta2 \,e_a + \sin\tfrac\theta2\,e_b$ and $\eta(u, u) = \eta_{aa}\cos^2\tfrac\theta2 + \eta_{bb}\sin^2\tfrac\theta2 = \eta_{aa}$. For a boost, $u = \eta_{aa}\cosh \tfrac\theta2\,e_a + \sinh\tfrac\theta2\,e_b$ and $\eta(u, u) = \eta_{aa} (\cosh^2 - \sinh^2) = \eta_{aa}$, since $\eta_{bb} = -\eta_{aa}$. Two unit vectors: the exponential lies in Spin(4,4).

(E) How an exponential moves the directions. Put $R(\theta) = \exp(\theta S)$ and $F_c(\theta) = R\gamma^cR^{-1}$. Since $dR/d\theta = SR = RS$ and $d(R^{-1})/d\theta = -SR^{-1}$, the product rule gives $dF_c/d\theta = R[S, \gamma^c]R^{-1} = \sum_d M_{dc}F_d$, with $F_c(0) = \gamma^c$. This linear system is solved by the matrix exponential: $\Lambda(R(\theta)) = \exp(\theta M)$. From the two entries of M^{ab}: $Me_a = -\eta_{aa}e_b$ and $Me_b = \eta_{bb} e_a$, so $M^2e_a = -\eta_{aa}\eta_{bb}e_a$ and

$$\Lambda e_a = \cos\theta\, e_a - \eta_{aa}\sin\theta\, e_b \ \text{(rotation)},
  \qquad \Lambda e_a = \cosh\theta\, e_a - \eta_{aa}\sinh\theta\, e_b
  \ \text{(boost)} .$$

(F) The forbidden band. Every vector matrix keeps the metric, $\Lambda^T\eta\Lambda = \eta$. In the space/time block form, $\eta = \mathrm{diag}(1_4, -1_4)$, and the top-left block of this equation reads $A^TA - C^TC = 1_4$ (the bottom-right one $D^TD - B^TB = 1_4$). For every column w of four numbers, $w^TA^TAw = w^Tw + w^TC^TCw$, that is $|Aw|^2 = |w|^2 + |Cw|^2 \geq |w|^2$. So every eigenvalue of the symmetric matrix A^TA is at least 1, and $(\det A)^2 = \det(A^TA) \geq 1$: **$\det A$ is never between -1 and

1**, and the same holds for $\det D$.

(G) Products of exponentials stay above the band. For $h = \exp(\theta_1 S_1)\cdots\exp(\theta_n S_n)$ put $h(t) = \exp(t\theta_1 S_1)\cdots\exp(t\theta_n S_n)$, $0 \le t \le 1$: a path from $h(0) = 1$ (with $\det A = 1$) to $h(1) = h$. The entries of $\Lambda(h(t))$ are sums of products of $\cos$, $\sin$, $\cosh$, $\sinh$ of multiples of t, so $\det A(t)$ is a continuous function of t. It starts at 1 and can never enter the band, so by the intermediate value theorem it stays ≥ 1; the same for $\det D$. **Every element of $\mathrm{Spin}_0(4,4)$ has the sign pattern $(+, +)$.**

(H) Four pieces. $\Lambda(\gamma^{(x0)}) = R_{e_{x0}}$ reverses only $x0$: pattern $(-, +)$. $\Lambda(\gamma^{(x4)})$ reverses only $x4$: $(+, -)$. $\Lambda(\gamma^{(x0)}\gamma^{(x4)})$ reverses both: $(-, -)$. For h in $\mathrm{Spin}_0(4,4)$ and w one of these, $\Lambda(hw) = \Lambda(h) \Lambda(w)$, and $\Lambda(w)$ is a diagonal matrix of signs: it only changes the sign of some columns of $\Lambda(h)$, so the space block of hw is A times a diagonal matrix of signs and hw has the pattern of w. Different patterns, so the four sets Spin_0, $\mathrm{Spin}_0\gamma^{(x0)}$, $\mathrm{Spin}_0\gamma^{(x4)}$, $\mathrm{Spin}_0\gamma^{(x0)}\gamma^{(x4)}$ have no element in common. In particular $\gamma^{(x0)}\gamma^{(x4)}$ lies in Spin(4,4) but is **not** a product of exponentials.

(I) Every unit vector is a turned basic one. Let v be a space-like unit vector, with space part σ (components $x0, x1, x2, x3$) and time part τ (components $x4, \dots, x7$), so $|\sigma|^2 - |\tau|^2 = 1$. Three stages carry e_{x0} to v: a boost in the plane $(x0, x4)$ gives $|\sigma|e_{x0} + |\tau|e_{x4}$; three rotations in the planes $(x4, x5)$, $(x4, x6)$, $(x4, x7)$ turn e_{x4} into $\tau/|\tau|$ and do not touch $x0$; three rotations in the planes $(x0, x1)$, $(x0, x2)$, $(x0, x3)$ turn e_{x0} into $\sigma/|\sigma|$ and do not touch the time part. The result is $\sigma + \tau = v$. The angles follow from (E). For an even h, $h\gamma^{(x0)}h^{-1} = \gamma(\Lambda(h)e_{x0}) = \gamma(v)$. A time-like unit vector v has $|\tau|^2 - |\sigma|^2 = 1$; three stages, with the roles of the two blocks exchanged, carry e_{x4} to v: a boost in the plane $(x4, x0)$ gives $|\tau|e_{x4} + |\sigma|e_{x0}$ (by (E) with $a = x4$, $\eta_{aa} = -1$: $\sinh\theta = |\sigma|$, so $\cosh\theta = \sqrt{1 + |\sigma|^2} = |\tau|$); three rotations in the planes $(x0, x1)$, $(x0, x2)$, $(x0, x3)$ turn e_{x0} into $\sigma/|\sigma|$ and do not touch $x4$; three rotations in the planes $(x4, x5)$, $(x4, x6)$, $(x4, x7)$ turn e_{x4} into $\tau/|\tau|$ and do not touch the space part. The result is again $\sigma + \tau = v$, and $h\gamma^{(x4)}h^{-1} = \gamma(\Lambda(h)e_{x4}) = \gamma(v)$. When the boost puts nothing on the other axis ($\tau = 0$ for a space-like, $\sigma = 0$ for a time-like v), $\theta = 0$ and the middle stage is left out.

(J) Moving the gammas to the right. Moving γ^e through $\gamma^a \gamma^b$ costs $(-1)^2 = +1$ when e is neither a nor b, and -1 when e is one of them. So $\gamma^e S^{ab}(\gamma^e)^{-1} = sS^{ab}$ with that sign s, and, term by term in the power series, $\gamma^e\exp(\theta S^{ab}) = \exp(s\theta S^{ab})\gamma^e$. A product of unit vectors, each written as in (I), becomes a product of exponentials followed by a word in $\gamma^{(x0)}$ and $\gamma^{(x4)}$; with $\gamma^{(x0)}\gamma^{(x0)} = 1$, $\gamma^{(x4)}\gamma^{(x4)} = -1$, $\gamma^{(x4)}\gamma^{(x0)} = -\gamma^{(x0)}\gamma^{(x4)}$ and $-1 = \exp(2\pi S^{(x1)(x2)})$, the word becomes one of 1, $\gamma^{(x0)}$, $\gamma^{(x4)}$, $\gamma^{(x0)}\gamma^{(x4)}$.

```
**The answer.** By (D) the exponentials, and by definition $\gamma^{(x0)}$ and
$\gamma^{(x4)}$, lie in Pin(4,4); by (I) and (J) every element of Pin(4,4) is a
product of them; by (G) and (H) the four pieces are different. So

$$\mathrm{Pin}(4,4) = \mathrm{Spin}_0 \cup \mathrm{Spin}_0\gamma^{(x0)} \cup
  \mathrm{Spin}_0\gamma^{(x4)} \cup \mathrm{Spin}_0\gamma^{(x0)}\gamma^{(x4)} ,$$

and $\mathrm{Spin}(4,4)$ is the union of the first and the last piece. The
exponentials of the scaled commutators generate exactly $\mathrm{Spin}_0(4,4)$;
together with $\gamma^{(x0)}$ and $\gamma^{(x4)}$ they generate all of Pin(4,4).
```

Text cell:

```
## 5. The gammas and the recorded checks

The next cell reads the gammas (exact whole numbers) from the record
‘Revision/algebra/gammas.json‘ and the two algebra reports. It defines the lists
‘SPACE‘ and ‘TIME‘ of the four space-like and the four time-like directions, the
$8 \times 8$ metric ‘ETA_MATRIX‘, and the helpers ‘recorded(key, name)‘ (true when
the report ‘key‘, "python" or "wolfram", holds the check ‘name‘ with the verdict
pass), ‘record_of(key, name)‘ (the text printed after "reproduces") and
‘check_reproduces(condition, name, record)‘, the helper ‘check‘ for a check that
reproduces a Revision record: it lets ‘check‘ print the PASS line and the line
"reproduces ..." into a text buffer (‘contextlib.redirect_stdout‘) and sends both
lines with one ‘sys.stdout.write‘, because Jupyter delivers printed text in pieces
and one piece keeps the two lines together for the tools that read the notebook.
Then it checks the Clifford relation.
```

In [2]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

PASS {gamma^a, gamma^b} = 2 eta^ab 1 for all 64 pairs
     reproduces Revision/algebra/reports/python-algebra.json, check clifford_relation
```

Text cell:

```
## 6. The 28 scaled commutators are independent

The next cell builds $S^{ab} = \tfrac14[\gamma^a, \gamma^b]$ for all 64 ordered
pairs (so $S^{aa} = 0$ and $S^{ba} = -S^{ab}$) as arrays of floating-point numbers;
their entries are $0$ and $\pm\tfrac12$, which the computer stores exactly. The
list ‘pairs‘ holds the 28 planes $(a, b)$ with $a$ before $b$ in the order
$x0, \dots, x7$. To test independence **exactly**, it writes each whole-number
matrix $2S^{ab} = \gamma^a\gamma^b$ as one row of 256 numbers and computes the rank
of the 28 rows with sympy’s ‘DomainMatrix‘ over the rational numbers ‘QQ‘
(Gaussian elimination with fractions): rank 28 means that no $S^{ab}$ is a
combination of the others.
```

In [3]:

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over QQ

S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4.0
     for a in COORDS for b in COORDS}  # all 64 ordered pairs; S^aa = 0
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 planes

def exact_rank(rows):

## 7. How the scaled commutators move the directions: a copy of so(4,4)

The next cell builds, for all 64 ordered pairs, the $8 \times 8$ matrix $M^{ab}$ of
section 4 (A), rows $d$ and columns $c$ in the order $x0, \dots, x7$, and checks
three things:

1. the vector rule $[S^{ab}, \gamma^c] = \sum_d M^{ab}_{dc}\gamma^d$ for the 28
   planes and the 8 directions $c$ (a recorded fact);
2. every $M^{ab}$ obeys $(M^{ab})^T\eta + \eta M^{ab} = 0$; the 28 of them are
   independent (exact rank 28); and the space so(4,4) has dimension exactly 28:
   the condition $X^T\eta + \eta X = 0$ is a system of 64 linear equations for the
   64 entries of an unknown $X$, with $(\eta X)_{rc} = \eta_{rr}X_{rc}$ and
   $(X^T\eta)_{rc} = X_{cr}\eta_{cc}$, whose solutions form a space of dimension
   64 minus the rank. So the $M^{ab}$ are a **basis** of so(4,4);
3. the commutators of the $M^{ab}$ follow the same table as those of the
   $S^{ab}$, $[X^{ab}, X^{cd}] = \eta^{bc}X^{ad} - \eta^{ac}X^{bd} -
   \eta^{bd}X^{ac} + \eta^{ad}X^{bc}$, for all $28 \times 28 = 784$ pairs (for the
   $S^{ab}$ a recorded fact).
```

## 9. The vector matrix of an exponential is exp(theta M)

The next cell defines `vector_matrix(g, odd)`, the vector matrix $\Lambda(g)$ of
the words list: it computes $\alpha(g)\gamma^cg^{-1}$ for each direction $c$ and
reads off $\Lambda_{dc} = \eta_{dd}\,\mathrm{tr}(\gamma^d\alpha(g)\gamma^cg^{-1})/16$
(because $\mathrm{tr}(\gamma^d\gamma^e) = 16\eta^{de}$). It checks, for all 28 planes
at $\theta = 0.9$, that $\Lambda(\exp(\theta S^{ab})) = \exp(\theta M^{ab})$ (the
matrix exponential summed as a power series), that it keeps the metric
($\Lambda^T\eta\Lambda = \eta$) and has determinant 1. Then it checks the turning
formulas of section 4 (E) for four planes used later: the rotations in
$(x0, x1)$ and $(x4, x5)$ and the boosts in $(x0, x4)$ and $(x4, x0)$.

## 12. Every unit vector is a turned gamma^(x0) or gamma^(x4)

The next cell implements the construction of section 4 (I).
‘turn_factor(a, b, along_a, along_b)‘ returns the factor $(a, b, \theta)$ whose
vector matrix carries $e_a$ to the direction of $\text{along}_a e_a +
\text{along}_b e_b$: from (E), for a rotation $\theta =
\mathrm{atan2}(-\eta_{aa}\text{along}_b, \text{along}_a)$ (‘np.arctan2(y, x)‘ is
the angle of the point $(x, y)$, so $\cos\theta$ and $\sin\theta$ are proportional
to $x$ and $y$), and for a boost (which needs $\text{along}_a^2 -
\text{along}_b^2 = 1$) $\theta = \mathrm{arcsinh}(-\eta_{aa}\text{along}_b)$.
```

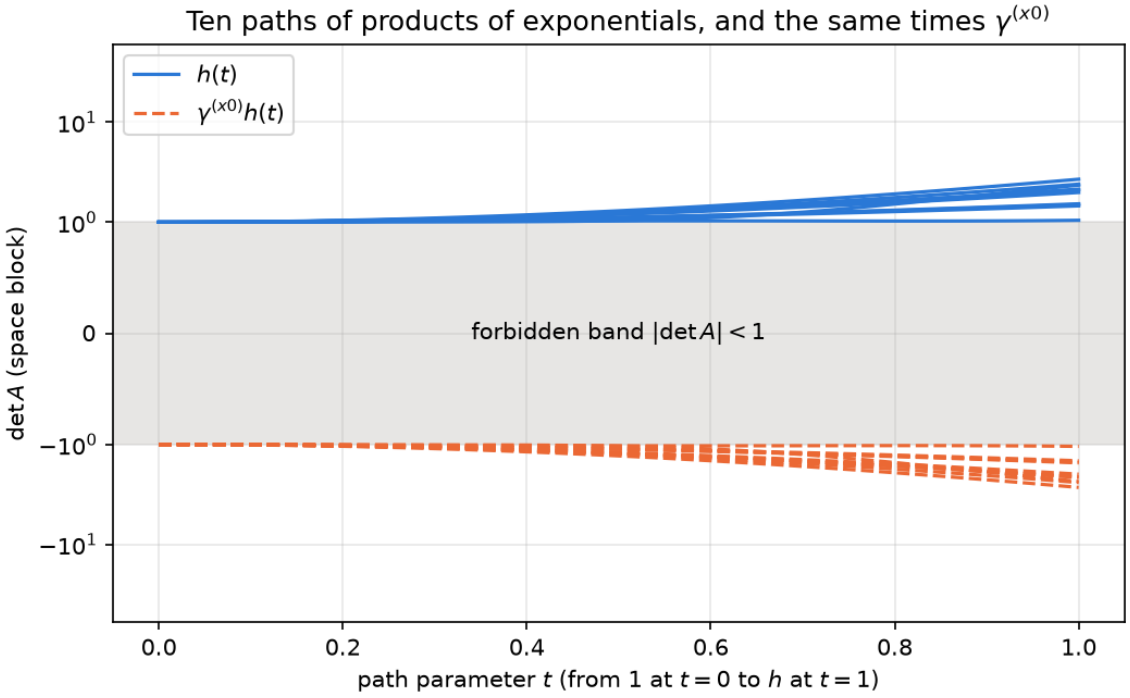

Figure 162: The determinant of the space block A of the vector matrix along ten paths $h(t)$ from the identity ($t = 0$) to a random product h of six exponentials ($t = 1$), solid blue, and along the odd elements $\gamma^{(x0)}h(t)$, dashed orange; horizontal axis t, vertical axis $\det A$ (linear between -1 and 1, logarithmic outside). The blue curves start at 1 and the orange at -1; the grey band $|\det A| < 1$ is forbidden for every element, so no curve can cross it: $\gamma^{(x0)}$ is not joined to 1 and is not a product of exponentials. (Notebook 05f, figure 4.)

‘block_rotation(axis, others, n)‘ carries e_{axis} to the unit vector n of one block by three rotations: the first turns part of the axis into the first other direction, keeping on the axis the length $\sqrt{n_{\text{axis}}^2 + \text{(squares of the remaining components)}}$, and so on; the last leaves exactly n_{axis} (which may be negative). ‘carry(v)‘ returns the factors (the first acts first) and the starting direction, $x0$ for a space-like and $x4$ for a time-like v. The cell checks the construction on 40 random unit vectors: each is a random column of 8 numbers from the normal distribution, kept when $|\eta(w, w)| \geq 0.5$ and divided by $\sqrt{|\eta(w, w)|}$. The checks: $\Lambda(h)e = v$ and, as 16×16 matrices, $h\gamma^eh^{-1} = \gamma(v)$.

## 13. Every element of Pin(4,4) is a product of exponentials times one of four

The next cell checks the rule of section 4 (J): $\gamma^e\exp(\theta S^{ab})
(\gamma^e)^{-1} = \exp(s\theta S^{ab})$ with $s = -1$ when $e$ is $a$ or $b$ and
$s = +1$ otherwise, for $e = x0, x4$ and all 28 planes.
```

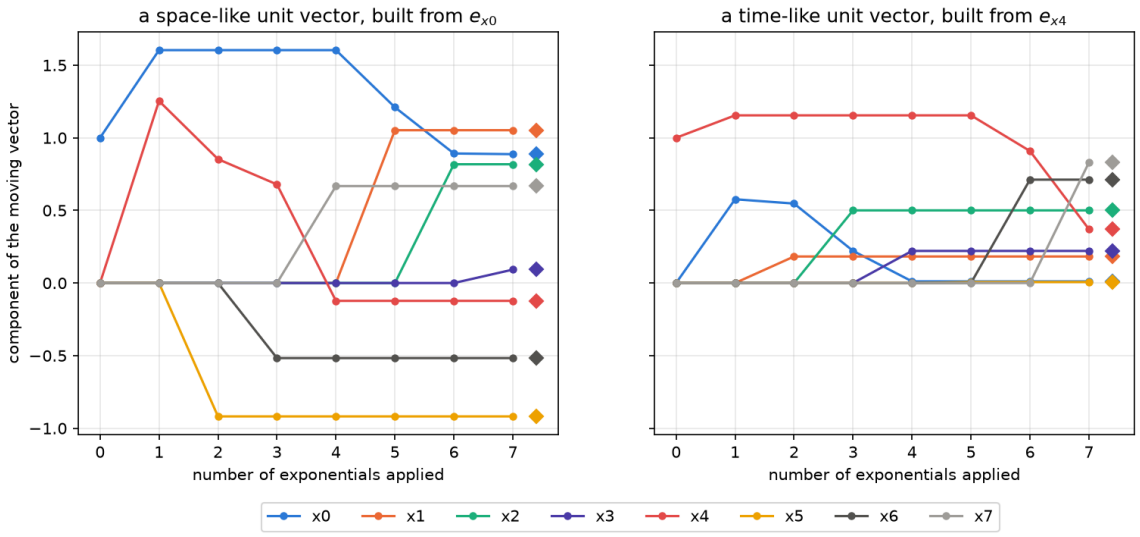

Figure 163: The construction that carries a basic unit vector to a given unit vector v by a product of exponentials: the eight components (one colour each, legend $x0$ to $x7$) of the moving vector after $0, 1, \ldots, 7$ exponentials (horizontal axis), for a random space-like v built from e_{x0} (left) and a random time-like v built from e_{x4} (right). The first step is a boost that shares the length between $x0$ and $x4$, the next three turn one block and the last three the other; the diamonds at the right are the components of v, which the last step reaches. Vertical axis: the components, pure numbers. (Notebook 05f, figure 5.)

The next cell writes 12 random elements $g = \gamma(v_1)\cdots\gamma(v_k)$ of
Pin(4,4) ($k = 1, \dots, 6$, twice each) in the form of section 4. A *word* is a
```

list of items in the order of the matrix product, each an exponential `("exp", a, b, theta)` or a gamma `("gamma", e)`; `evaluate(word)` multiplies it out. `word_of(v)` is the word of $\gamma(v) = h\gamma^eh^{-1}$ (with h^{-1} the factors in the opposite order with the opposite angles). `move_gammas_right(word)` moves every gamma to the right end with the rule just checked, and `reduce_gammas` writes the remaining product of gammas as $\pm$ one of the four words; a sign -1 is replaced by the exponential $\exp(2\pi S^{(x1)(x2)}) = -1$. For each element the cell checks that the word equals g, that the final product of exponentials times the word w equals g (relative difference below 10^{-9}), and that g has the sign pattern of w.

## 14. What the group elements span

The *span* of a group (all combinations of its elements) is closed under products,
because the product of two elements is an element. For $\mathrm{Spin}_0(4,4)$:
$\exp(\pi S^{ab}) = \gamma^a\gamma^b$ for a rotation ($\cos\tfrac\pi2 = 0$,
$\sin\tfrac\pi2 = 1$) and $(\exp(\theta S^{ab}) - \exp(-\theta S^{ab}))/
(2\sinh\tfrac\theta2) = \gamma^a\gamma^b$ for a boost, so the span contains every
$\gamma^a\gamma^b$, hence every product of an even number of gammas: all 128 even
Clifford products, which span the block-diagonal matrices. Every element is even,
so the span is exactly these 128 dimensions. With one gamma added, the span of
Pin(4,4) is all 256. The next cell checks the two formulas for all 28 planes and
then measures the rank of the first $n$ elements of two random lists, $n = 1, 2,
\dots$: 170 random products of six exponentials, and 300 random elements $hw$ with
$w$ running through the four words. The rank is computed from the *singular
values* (‘np.linalg.svd‘; a list of numbers whose count above a small threshold,
here $10^{-9}$ times the largest, is the rank).
```

In [17]:

```
formula_ok = all(

```

Text cell:

```
## 16. What this notebook showed

- PROVED (section 4, line by line) and CHECKED on the matrices: the 28 scaled
  commutators $S^{ab} = \tfrac14[\gamma^a, \gamma^b]$ of the Revision gammas are
  independent; the matrices $M^{ab}$ by which they move the eight directions are
  a basis of so(4,4) (dimension 28) with the same commutators, so the $S^{ab}$ span
  an exact copy of so(4,4). The recorded checks S_definition, S_vector_action and
  S_lorentz_algebra are reproduced.
- PROVED and CHECKED: every $\exp(\theta S^{ab}) = \gamma^a\gamma(u)$ is a product
  of two unit vectors, so the exponentials lie in Spin(4,4); its vector matrix is
  $\exp(\theta M^{ab})$.
- PROVED: the space block and the time block of every vector matrix have
  determinants outside the band $(-1, 1)$; along a path from 1 they cannot change
  sign. So all products of exponentials, the group $\mathrm{Spin}_0(4,4)$, have
  the sign pattern $(+, +)$, while $\gamma^{(x0)}$, $\gamma^{(x4)}$ and
  $\gamma^{(x0)}\gamma^{(x4)}$ have $(-, +)$, $(+, -)$, $(-, -)$.
- PROVED by an explicit construction and CHECKED on 40 random unit vectors: every
  $\gamma(v)$ is $h\gamma^{(x0)}h^{-1}$ or $h\gamma^{(x4)}h^{-1}$ with $h$ a product
  of at most seven exponentials; CHECKED on 12 random elements: every element of
  Pin(4,4) is a product of exponentials times exactly one of $1$, $\gamma^{(x0)}$,
  $\gamma^{(x4)}$, $\gamma^{(x0)}\gamma^{(x4)}$.
- THE ANSWER: the exponentials of the scaled commutators generate exactly
  $\mathrm{Spin}_0(4,4)$, the part of Pin(4,4) joined to 1; adding the two gammas
  $\gamma^{(x0)}$ and $\gamma^{(x4)}$ generates all of Pin(4,4), which has four
  pieces, and Spin(4,4) is the union of the two even pieces. It is not correct to
  say that the scaled commutators alone generate Pin(4,4).
- COMPUTED: the elements of $\mathrm{Spin}_0(4,4)$ span the 128 block-diagonal
  matrices and those of Pin(4,4) all 256, the ranks recorded for the even and for
  all Clifford products.
```

5.27 Line-by-line walk-through of Notebook 05f

The notebook has 19 code cells. In [1] is the set-up cell of Section 5.10 with `NOTEBOOK_ID = "05f"`; its comments repeat the instructions of Section 5.25. Docstrings are left out of the quotations and long captions are replaced by a line `...`), as in Section 5.10.

In [2], the gammas and the recorded checks.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
ETA_MATRIX = np.diag([float(ETA[x]) for x in COORDS])  # the 8 x 8 metric eta
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the 16 x 16 identity matrix 1
SPACE = ["x0", "x1", "x2", "x3"]  # the four space-like directions
TIME = ["x4", "x5", "x6", "x7"]  # the four time-like directions
```

The gammas are read as in Notebook 05d; `ETA_MATRIX` is the 8×8 metric. New are the lists `SPACE` and `TIME` of the space-like and time-like directions, in the order used for the blocks of step (F).

```
REPORT_FILES = {"python": "Revision/algebra/reports/python-algebra.json",
                "wolfram": "Revision/algebra/reports/wolfram-algebra.json"}

                 record=record_of("python", "clifford_relation"))
```

The reports, the helpers and the Clifford check are those of Notebook 05d, In [2] (Section 5.22).

In [3], the 28 generators are independent.

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over QQ

S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4.0
     for a in COORDS for b in COORDS}  # all 64 ordered pairs; S^aa = 0
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 planes

def exact_rank(rows):
    whole = [[int(round(x)) for x in row] for row in rows]  # entries 0, +1, -1
    return DomainMatrix.from_list(whole, sp.QQ).rank()
```

`S` and `pairs` are those of Notebook 05d. `exact_rank` takes a list of rows whose entries are whole numbers stored as floating-point numbers, turns each entry into a Python whole number (`int(round(x))`), and computes the rank exactly over the rational numbers, as in Notebook 05b.

```
rank_S = exact_rank([(gamma[a] @ gamma[b]).reshape(256) for a, b in pairs])
entries = sorted({float(v) for p in pairs for v in S[p].flat})
say(f"{len(pairs)} generators; their entries are {entries}; exact rank {rank_S}")
check_reproduces(rank_S == 28 and entries == [-0.5, 0.0, 0.5]
                 and all(np.array_equal(S[(a, b)], gamma[a] @ gamma[b] / 2.0)
                         for a, b in pairs)
                 and recorded("python", "S_definition"),
                 "the 28 S^ab = (1/2) gamma^a gamma^b are linearly independent "
                 "(exact rank 28)",
                 record=record_of("python", "S_definition"))
```

The 28 whole-number matrices $2S^{ab} = \gamma^a\gamma^b$, each written as a row of 256 numbers, have the exact rank 28 (printed together with the entries -0.5, 0, 0.5 of the S^{ab}): no generator is a combination of the others.

In [4], the matrices M^{ab}: a copy of so(4,4).

```
def generator_matrix(a, b):
    result = np.zeros((8, 8))
    for j, c in enumerate(COORDS):
        for i, d in enumerate(COORDS):
            result[i, j] = eta(b, c) * (d == a) - eta(a, c) * (d == b)
    return result

M = {(a, b): generator_matrix(a, b) for a in COORDS for b in COORDS}  # all 64
```

`generator_matrix(a, b)` fills the 8×8 matrix of step (A), $M^{ab}_{dc} = \eta^{bc}\delta_{da} - \eta^{ac}\delta_{db}$, entry by entry: `(d == a)` is true or false, which Python counts as 1 or 0, so it plays the role of δ_{da}. `M` holds the matrices for all 64 ordered pairs.

```
vector_ok = all(
    np.array_equal(S[p] @ gamma[c] - gamma[c] @ S[p],
                   sum(M[p][i, j] * gamma[d] for i, d in enumerate(COORDS)))
    for p in pairs for j, c in enumerate(COORDS))
check_reproduces(vector_ok and recorded("python", "S_vector_action")
                 and recorded("wolfram", "S_gamma_commutator"),
                 "[S^ab, gamma^c] = sum_d M^ab_dc gamma^d with M_dc = eta^bc delta_da "
                 "- eta^ac delta_db",
                 record=record_of("python", "S_vector_action"))
```

For the 28 planes and the 8 directions c the commutator $[S^{ab}, \gamma^c]$ is compared with $\sum_d M^{ab}_{dc}\gamma^d$: the vector rule in the form of step (A).

```
in_so44 = all(not (M[p].T @ ETA_MATRIX + ETA_MATRIX @ M[p]).any() for p in pairs)
rank_M = exact_rank([M[p].reshape(64) for p in pairs])
equations = []  # the 64 equations (X^T eta + eta X)_rc = 0 for the entries of X
for r in range(8):
    for c in range(8):
        row = np.zeros(64)
        row[r * 8 + c] += ETA_MATRIX[r, r]  # (eta X)_rc = eta_rr X_rc
        row[c * 8 + r] += ETA_MATRIX[c, c]  # (X^T eta)_rc = X_cr eta_cc
        equations.append(row)
dimension_so44 = 64 - exact_rank(equations)
say(f"rank of the 28 matrices M^ab: {rank_M}; dimension of so(4,4): "
    f"{dimension_so44}")
check(in_so44 and rank_M == 28 and dimension_so44 == 28,
      "every M^ab lies in so(4,4), the 28 M^ab are independent and so(4,4) has "
      "dimension 28: the M^ab are a basis of so(4,4)")
```

Step (B) in three parts. `in_so44`: every M^{ab} obeys $(M^{ab})^T\eta + \eta M^{ab} = 0$. `rank_M`: the 28 matrices, each written as a row of 64 numbers, have rank 28. `equations`: the condition $X^T\eta + \eta X = 0$ for an unknown 8×8 matrix X is written as 64 linear equations for its 64 entries, listed row by row (the entry X_{rc} is unknown number $8r + c$). The entry (r, c) of ηX is $\eta_{rr}X_{rc}$ and that of $X^T\eta$ is $X_{cr}\eta_{cc}$, so equation (r, c) has the coefficient η_{rr} at the place of X_{rc} and η_{cc} at the place of X_{cr} (`+=` adds, so that on the diagonal, where the two places coincide, both contributions count). The dimension of so(4,4) is 64 minus the rank of these equations. The printed line shows 28 and 28.

```
def table_failures(X):
    failures = 0
    for a, b in pairs:
        for c, d in pairs:
            right = (eta(b, c) * X[(a, d)] - eta(a, c) * X[(b, d)]
                     - eta(b, d) * X[(a, c)] + eta(a, d) * X[(b, c)])
            if not np.array_equal(X[(a, b)] @ X[(c, d)] - X[(c, d)] @ X[(a, b)],
                                  right):
                failures += 1
    return failures

failures_S, failures_M = table_failures(S), table_failures(M)
say(f"pairs that break the table: S^ab {failures_S}, M^ab {failures_M} (of 784)")
```

```
check_reproduces(failures_S == 0 and failures_M == 0
                 and recorded("python", "S_lorentz_algebra")
                 and recorded("wolfram", "S_Lorentz_algebra"),
                 "the S^ab and the M^ab have the same commutators: the S^ab span an "
                 "exact copy of so(4,4)",
                 record=record_of("python", "S_lorentz_algebra"))
```

`table_failures` counts the pairs of planes for which a family of 64 matrices breaks the so(4,4) commutation table. It is applied to the S^{ab} (a recorded fact) and to the M^{ab} (step (C)): 0 failures of 784 for both.

In [5], the shape of the M^{ab}.

```
from matplotlib.colors import LinearSegmentedColormap

SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
shape_ok = all(
    np.count_nonzero(M[(a, b)]) == 2
    and np.array_equal(M[(a, b)].T, -ETA[a] * ETA[b] * M[(a, b)]) for a, b in pairs)
check(shape_ok, "each M^ab has two nonzero entries; antisymmetric for the 12 "
      "rotations, symmetric for the 16 boosts")
```

Step (A) predicts two nonzero entries (η_{bb} and $-\eta_{aa}$ in mirrored places). They have opposite signs, so the matrix is antisymmetric, when $\eta_{aa}\eta_{bb} = +1$ (a rotation), and equal signs, so it is symmetric, for a boost: in one formula $(M^{ab})^T = -\eta_{aa}\eta_{bb}M^{ab}$. `np.count_nonzero` counts the nonzero entries.

```
fig, axes = plt.subplots(4, 7, figsize=(14.0, 8.8))
numbers = [x[1] for x in COORDS]  # the tick labels 0, ..., 7
for ax, (a, b) in zip(axes.flat, pairs):
    ax.imshow(M[(a, b)], cmap=SIGNS, vmin=-1, vmax=1)
    kind = "rotation" if ETA[a] * ETA[b] == 1 else "boost"
    ax.set_title(f"$M^{{{a}\\,{b}}}$, {kind}", fontsize=9)
    ax.set_xticks(range(8), numbers, fontsize=6)
    ax.set_yticks(range(8), numbers, fontsize=6)
    ax.grid(False)
fig.suptitle("The 28 matrices $M^{ab}$: how $S^{ab}$ moves the directions "
             "$x0$ to $x7$ (rows and columns numbered 0 to 7)")
save_figure(fig, "generator_matrices",
            ...)
```

A grid of 4 rows and 7 columns of small pictures, one per plane (`axes.flat` runs through the 28 picture areas). `x[1]` is the second character of a name such as `x5`, so the tick labels are the numbers 0 to 7. In the f-string of the title, three braces `{{{a}` give one literal brace followed by the value of `a`, and `\\,` a small space. `fig.suptitle` is a title over the whole figure. In `05f_1_generator_matrices.png` every small picture has exactly two coloured squares, mirrored about the diagonal: of opposite colours for the 12 rotations, of the same colour for the 16 boosts.

In [6], the exponential and its two factors.

```
def exponential(a, b, theta):
    J = (gamma[a] @ gamma[b]).astype(float)  # J = 2 S^ab, J J = -eta_aa eta_bb
```

```
    if ETA[a] * ETA[b] == 1:  # J J = -1: a rotation
        return np.cos(theta / 2) * np.eye(16) + np.sin(theta / 2) * J
    return np.cosh(theta / 2) * np.eye(16) + np.sinh(theta / 2) * J  # a boost

def series_exponential(X, terms=60):
    result = np.eye(X.shape[0])
    term = np.eye(X.shape[0])
    for k in range(1, terms):
        term = term @ X / k  # X^k / k! from X^(k-1) / (k-1)!
        result = result + term
    return result
```

`exponential` is the closed formula and `series_exponential` the power series, here summed to 60 terms; both work as `spin_transformation` and `exp_series` of Notebook 05d (Section 5.22, In [6]). `series_exponential` also serves for the 8×8 matrix exponential $\exp(\theta M)$ in In [8].

```
def gamma_of(v):
    return sum(v[i] * gamma[x].astype(float) for i, x in enumerate(COORDS))

def metric_product(u, v):
    return float(u @ ETA_MATRIX @ v)

def second_factor(a, b, theta):
    i, j = COORDS.index(a), COORDS.index(b)
    if ETA[a] * ETA[b] == 1:  # a rotation
        return ETA[a] * np.cos(theta / 2) * E8[i] + np.sin(theta / 2) * E8[j]
    return ETA[a] * np.cosh(theta / 2) * E8[i] + np.sinh(theta / 2) * E8[j]

E8 = np.eye(8)  # E8[i] is the basic unit vector of the direction COORDS[i]
```

`gamma_of` and `metric_product` are $\gamma(v)$ and $\eta(u, v)$ as in Notebook 05d. `second_factor(a, b, theta)` is the unit vector u of step (D): $\eta_{aa} \cos\frac{\theta}{2}\, e_a + \sin\frac{\theta}{2}\, e_b$ for a rotation and the same with cosh and sinh for a boost. `E8[i]` is the basic unit vector of the direction number `i`; the function uses `E8`, which is defined in the line after it, before the function is first called, so this is allowed.

```
series_gap = max(np.max(np.abs(series_exponential(0.9 * S[p]) - exponential(*p, 0.9)))
                 for p in pairs)
check(series_gap < 1e-10, "the closed formula equals the power series of "
      "exp(theta S^ab) for all 28 planes (difference below 1e-10)")
factor_ok = True
for a, b in pairs:
    for theta in [-2.5, -0.4, 0.9, 2.2, 5.0]:
        u = second_factor(a, b, theta)
        factor_ok &= (np.allclose(gamma[a] @ gamma_of(u), exponential(a, b, theta),
                                  rtol=0.0, atol=1e-10)
                      and abs(metric_product(u, u) - ETA[a]) < 1e-10)
check(factor_ok, "exp(theta S^ab) = gamma^a gamma(u) with eta(u, u) = eta_aa: a "
      "product of two unit vectors (28 planes, 5 values each)")
```

The first check compares the closed formula with the series for all 28 planes at $\theta = 0.9$. The second checks step (D) for all 28 planes at five values of θ: $\exp(\theta S^{ab}) = \gamma^a \gamma(u)$ and $\eta(u, u) = \eta_{aa}$. (`rtol=0.0, atol=1e-10` makes `np.allclose` accept only differences below 10^{-10}, without a relative tolerance.)

In [7], the picture of the second factor.

```
cases = [("x1", "x2", np.linspace(0.0, 4 * np.pi, 241)),
         ("x1", "x4", np.linspace(-3.0, 3.0, 241)),
         ("x4", "x0", np.linspace(-3.0, 3.0, 241))]
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.6))
norm_ok = True  # eta(u, u) = eta_aa along all three curves
for ax, (a, b, thetas) in zip(axes, cases):
    points = np.array([second_factor(a, b, th) for th in thetas])
    i, j = COORDS.index(a), COORDS.index(b)
    norms = [metric_product(p, p) for p in points]
    norm_ok &= max(abs(n - ETA[a]) for n in norms) < 1e-10
    ax.plot(points[:, i], points[:, j], color="#2a78d6", linewidth=2)
    marks = points[::40]  # every 40th value of theta
    ax.plot(marks[:, i], marks[:, j], "o", color="#eb6834", markersize=6)
    kind = "rotation" if ETA[a] * ETA[b] == 1 else "boost"
    ax.set_title(f"{kind} in $({a}, {b})$: $\\eta(u, u) = {norms[0]:+.0f}$")
    ax.set_xlabel(f"$u_{{{a}}}$")
    ax.set_ylabel(f"$u_{{{b}}}$")
    ax.set_aspect("equal")
    ax.set_xlim(-4.2, 4.2)
    ax.set_ylim(-4.2, 4.2)
check(norm_ok, "along the three curves eta(u, u) stays equal to eta_aa")
save_figure(fig, "two_unit_vectors",
            ...)
```

For three planes (a rotation over θ from 0 to 4π and two boosts over -3 to 3) the cell computes the second factor u at 241 values and plots its two nonzero components against each other, with an orange dot every 40th value. The check confirms $\eta(u, u) = \eta_{aa}$ along all three curves, and each title prints this value ($+1$ for the planes starting with $x1$, -1 for the plane $(x4, x0)$). In `05f_2_two_unit_vectors.png` the rotation's u runs once around the unit circle, and the boosts' u run along branches of hyperbolas.

In [8], the vector matrix of an exponential.

```
def vector_matrix(g, odd=False):
    g_inverse = np.linalg.inv(g)
    sign = -1.0 if odd else 1.0
    result = np.zeros((8, 8))
    for j, c in enumerate(COORDS):
        moved = sign * (g @ gamma[c] @ g_inverse)  # alpha(g) gamma^c g^-1
        for i, d in enumerate(COORDS):
            result[i, j] = ETA[d] * np.trace(gamma[d] @ moved) / 16.0
    return result
```

`vector_matrix(g, odd)` is the vector matrix of Section 5.12 with the twisted action: for an odd

element (`odd=True`) the moved gamma gets the sign -1. Otherwise it is the trace formula of Notebook 05d.

```
exp_ok = True
for p in pairs:
    Lam = vector_matrix(exponential(*p, 0.9))
    exp_ok &= (np.allclose(Lam, series_exponential(0.9 * M[p]), rtol=0.0, atol=1e-12)
               and np.allclose(Lam.T @ ETA_MATRIX @ Lam, ETA_MATRIX, atol=1e-12)
               and abs(np.linalg.det(Lam) - 1.0) < 1e-12)
check(exp_ok, "the vector matrix of exp(theta S^ab) is exp(theta M^ab); it keeps "
      "the metric and has determinant 1 (28 planes)")
```

Step (E) for all 28 planes at $\theta = 0.9$: the vector matrix of the spinor exponential equals the 8×8 exponential $\exp(0.9\, M^{ab})$, keeps the metric and has determinant 1.

```
def turned_axis(a, b, theta):
    i, j = COORDS.index(a), COORDS.index(b)
    if ETA[a] * ETA[b] == 1:  # a rotation
        return np.cos(theta) * E8[i] - ETA[a] * np.sin(theta) * E8[j]
    return np.cosh(theta) * E8[i] - ETA[a] * np.sinh(theta) * E8[j]  # a boost

turn_ok = all(
    np.allclose(vector_matrix(exponential(a, b, th))[:, COORDS.index(a)],
                turned_axis(a, b, th), rtol=0.0, atol=1e-12)
    for a, b in [("x0", "x1"), ("x4", "x5"), ("x0", "x4"), ("x4", "x0")]
    for th in [-1.3, 0.4, 2.0])
check(turn_ok, "Lambda e_a = cos(theta) e_a - eta_aa sin(theta) e_b for a rotation "
      "and cosh(theta) e_a - eta_aa sinh(theta) e_b for a boost")
```

`turned_axis` is the formula of step (E) for Λe_a. The check compares it with column a of the computed vector matrix for the four planes used by the construction of step (I) ($(x0, x1)$, $(x4, x5)$, $(x0, x4)$, $(x4, x0)$; note that the order of a and b matters) at three values each.

In [9], the block equations on random products.

```
SPACE_INDEX = [COORDS.index(x) for x in SPACE]  # the positions of x0, x1, x2, x3
TIME_INDEX = [COORDS.index(x) for x in TIME]  # the positions of x4, x5, x6, x7

def blocks(Lam):
    return (Lam[np.ix_(SPACE_INDEX, SPACE_INDEX)], Lam[np.ix_(SPACE_INDEX, TIME_INDEX)],
            Lam[np.ix_(TIME_INDEX, SPACE_INDEX)], Lam[np.ix_(TIME_INDEX, TIME_INDEX)])
```

`SPACE_INDEX` is the list of positions $[0, 1, 2, 3]$ of $x0, x1, x2, x3$ and `TIME_INDEX` the list $[4, 5, 6, 7]$ of $x4, x5, x6, x7$. `np.ix_(rows, columns)` picks the entries in the listed rows and columns, so `blocks` returns the four 4×4 blocks A, B', C', D of step (F).

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed
```

```
def random_factors(count):
    factors = []
    for _ in range(count):
        a, b = pairs[int(rng.integers(28))]  # a random plane
        if ETA[a] * ETA[b] == 1:  # a rotation: an angle from 0 to 2 pi
            theta = rng.uniform(0.0, 2 * np.pi)
        else:  # a boost: a rapidity from -1 to 1
            theta = rng.uniform(-1.0, 1.0)
        factors.append((a, b, float(theta)))
    return factors
```

The random-number generator starts from the fixed seed 12345; every later cell draws from the same generator in the same order, so every run makes the same choices. `random_factors(count)` draws `count` factors (a, b, θ): a plane chosen at random from the 28 (`rng.integers(28)` is a whole number from 0 to 27), with a uniformly random angle in $[0, 2\pi)$ for a rotation or a rapidity in $[-1, 1)$ for a boost (`rng.uniform(low, high)`). The loop variable `_` is a name for a value that is not used.

```
def compose(factors, t=1.0):
    g = np.eye(16)
    for a, b, theta in factors:
        g = exponential(a, b, t * theta) @ g
    return g
```

`compose(factors, t)` multiplies the exponentials $\exp(t\theta_j S_j)$ in the order of the list, each new one on the left: the result is $\exp(t\theta_n S_n)\cdots\exp(t\theta_1 S_1)$, in which the first factor of the list acts first on a column. With t running from 0 to 1 it is the path $h(t)$ of step (G).

```
block_ok, smallest = True, np.inf
for _ in range(200):
    A, B_, C_, D = blocks(vector_matrix(compose(random_factors(6))))
    block_ok &= (np.allclose(A.T @ A - C_.T @ C_, np.eye(4), atol=1e-9)
                 and np.allclose(D.T @ D - B_.T @ B_, np.eye(4), atol=1e-9))
    smallest = min(smallest, np.linalg.det(A), np.linalg.det(D))
report("smallest det A or det D of 200 products of six exponentials",
       f"{smallest:.3f}")
check(block_ok and smallest > 1.0 - 1e-9,
      "200 products of exponentials: A^T A - C^T C = 1, D^T D - B^T B = 1, and "
      "det A >= 1, det D >= 1")
```

For 200 random products of six exponentials the cell checks the two block equations of step (F) (the blocks are named `B_` and `C_` so as not to overwrite other names) and keeps the smallest of all determinants of A and D, starting from `np.inf` (infinity). The RESULT line prints it, 1.000, and the check requires it to be at least 1 (up to 10^{-9}): every product has the sign pattern $(+,+)$, step (G). The smallest value is the bound itself: one of the 200 random products is made of six rotations only (in the planes $(x1, x2)$, $(x0, x1)$, $(x4, x7)$, $(x6, x7)$, $(x2, x3)$ and $(x1, x2)$), and a rotation does not mix space with time, so $C' = B' = 0$, the block equations give $A^T A = D^T D = 1_4$, and $\det A = \det D = 1$ exactly.

In [10], the four words and the four pieces.

```
WORDS = {"1": (I16, False), "gamma^(x0)": (gamma["x0"], True),
         "gamma^(x4)": (gamma["x4"], True),
         "gamma^(x0) gamma^(x4)": (gamma["x0"] @ gamma["x4"], False)}

def pattern(Lam):
    A, _, _, D = blocks(Lam)
    return (int(np.sign(np.linalg.det(A))), int(np.sign(np.linalg.det(D))))
```

`WORDS` stores the four words 1, $\gamma^{(x0)}$, $\gamma^{(x4)}$, $\gamma^{(x0)}\gamma^{(x4)}$, each with the flag that says whether it is odd. `pattern` returns the sign pattern of a vector matrix: the signs (`np.sign`) of $\det A$ and $\det D$; the two middle blocks are not needed and are given the throw-away name `_`.

```
flip0 = np.diag([-1.0, 1, 1, 1, 1, 1, 1, 1])  # reverses x0 only (position 0)
flip4 = np.diag([1.0, 1, 1, 1, -1, 1, 1, 1])  # reverses x4 only (position 4)
expected = {"1": np.eye(8), "gamma^(x0)": flip0, "gamma^(x4)": flip4,
            "gamma^(x0) gamma^(x4)": flip0 @ flip4}
words_ok = all(np.allclose(vector_matrix(w.astype(float), odd), expected[name])
               for name, (w, odd) in WORDS.items())
for name, (w, odd) in WORDS.items():
    say(f"{name:22} sign pattern (sign det A, sign det D) = "
        f"{pattern(vector_matrix(w.astype(float), odd))}")
check(words_ok, "the vector matrices of 1, gamma^(x0), gamma^(x4), gamma^(x0) "
      "gamma^(x4) are the identity and the reversals of x0, x4 and both")
```

The predicted vector matrices of step (H) are diagonal matrices of signs. The check compares them with the computed ones (the twisted action for the two odd words), and the four printed lines show the patterns $(1,1)$, $(-1,1)$, $(1,-1)$, $(-1,-1)$.

```
points = {}  # word -> list of (det A, det D)
pieces_ok = True
for name, (w, odd) in WORDS.items():
    points[name] = []
    Lam_w = vector_matrix(w.astype(float), odd)
    for _ in range(60):
        h = compose(random_factors(6))
        Lam = vector_matrix(h @ w, odd)
        pieces_ok &= (np.allclose(Lam, vector_matrix(h) @ Lam_w, atol=1e-9)
                      and pattern(Lam) == pattern(Lam_w))
        A, _, _, D = blocks(Lam)
        points[name].append((np.linalg.det(A), np.linalg.det(D)))
check(pieces_ok, "for 4 x 60 elements h w: Lambda(h w) = Lambda(h) Lambda(w), and h w "
      "has the sign pattern of w")
```

For each word w and 60 random products h the cell checks $\Lambda(hw) = \Lambda(h)\Lambda(w)$ and that hw has the pattern of w, and stores the pair $(\det A, \det D)$ for the picture.

```
# An observation that the picture below shows and that the proof does not need:
# for every one of the 240 elements the two determinants have the same size.
equal_size = all(abs(abs(dA) - abs(dD)) < 1e-9 * max(abs(dA), 1.0)
                 for name in WORDS for dA, dD in points[name])
check(equal_size, "observed for all 240 elements: |det A| = |det D|")
```

An observation, checked but not used by the proof: for all 240 elements $|\det A| = |\det D|$, to a relative accuracy of 10^{-9}. It is COMPUTED for these 240 elements only; the book neither proves nor uses it.

In [11], the picture of the four pieces.

```
colors = {"1": "#2a78d6", "gamma^(x0)": "#eb6834", "gamma^(x4)": "#1baf7a",
          "gamma^(x0) gamma^(x4)": "#4a3aa7"}
labels = {"1": r"$h$ (products of exponentials)",
          "gamma^(x0)": r"$h\gamma^{(x0)}$",
          "gamma^(x4)": r"$h\gamma^{(x4)}$",
          "gamma^(x0) gamma^(x4)": r"$h\gamma^{(x0)}\gamma^{(x4)}$"}
fig, ax = plt.subplots(figsize=(7.4, 6.6))
ax.axvspan(-1.0, 1.0, color="#d8d6d2", alpha=0.6, linewidth=0)
ax.axhspan(-1.0, 1.0, color="#d8d6d2", alpha=0.6, linewidth=0)
for name in WORDS:
    values = np.array(points[name])
    ax.plot(values[:, 0], values[:, 1], "o", color=colors[name], markersize=5,
            label=labels[name])
ax.set_xscale("symlog", linthresh=1.0)

save_figure(fig, "four_pieces",
            ...)
```

`axvspan` and `axhspan` shade the vertical and the horizontal band between -1 and 1 in grey. The 240 points are drawn in four colours, one per word. `set_xscale("symlog", linthresh=1.0)` makes an axis **symmetric logarithmic**: linear between -1 and 1 and logarithmic outside, so that values from 1 to 60 and the band are visible together. In `05f_3_four_pieces.png` each colour fills one of the four corners outside the band, and the products of exponentials (blue) never leave the corner where both determinants are at least 1.

In [12], paths from 1.

```
path_t = np.linspace(0.0, 1.0, 101)  # t = 0, 0.01, ..., 1
curves_h, curves_g0 = [], []  # det A(t) along h(t) and along gamma^(x0) h(t)
g0 = gamma["x0"].astype(float)
for _ in range(10):
    factors = random_factors(6)
    along_h, along_g0 = [], []
    for t in path_t:
        h = compose(factors, t)
        along_h.append(np.linalg.det(blocks(vector_matrix(h))[0]))
        along_g0.append(np.linalg.det(blocks(vector_matrix(g0 @ h, odd=True))[0]))
    curves_h.append(along_h)
```

```
    curves_g0.append(along_g0)
curves_h, curves_g0 = np.array(curves_h), np.array(curves_g0)
check(np.all(curves_h > 1.0 - 1e-9) and np.all(curves_g0 < -1.0 + 1e-9)
      and np.allclose(curves_h[:, 0], 1.0) and np.allclose(curves_g0[:, 0], -1.0),
      "along ten paths t -> h(t) det A stays >= 1, and along gamma^(x0) h(t) it "
      "stays <= -1")
```

For ten random products of six exponentials the cell follows the path $h(t)$ of step (G) at 101 values of t and records $\det A(t)$ (`blocks(...)[0]` is the space block), and the same for the odd elements $\gamma^{(x0)}h(t)$. The check: the first family starts at 1 and stays at or above 1, the second starts at -1 and stays at or below -1.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
ax.axhspan(-1.0, 1.0, color="#d8d6d2", alpha=0.6, linewidth=0)
for k in range(10):
    ax.plot(path_t, curves_h[k], color="#2a78d6", linewidth=1.5,
            label=r"$h(t)$" if k == 0 else None)
    ax.plot(path_t, curves_g0[k], color="#eb6834", linewidth=1.5, linestyle="--",
            label=r"$\gamma^{(x0)}h(t)$" if k == 0 else None)
ax.set_yscale("symlog", linthresh=1.0)
ax.set_ylim(-60, 60)
ax.text(0.5, 0.0, "forbidden band $|\\det A| < 1$", ha="center", va="center")
ax.set_xlabel("path parameter $t$ (from 1 at $t = 0$ to $h$ at $t = 1$)")
ax.set_ylabel("$\\det A$ (space block)")
ax.set_title("Ten paths of products of exponentials, and the same times "
             "$\\gamma^{(x0)}$")
ax.legend(loc="upper left")
save_figure(fig, "paths_and_band",
            ...)
```

The twenty curves are drawn over the grey band (only the first curve of each family gets a legend label; `None` means no label). In `05f_4_paths_and_band.png` the blue curves start at 1 and stay above the band, the orange ones start at -1 and stay below it: no curve crosses the band, which is why $\gamma^{(x0)}$ cannot be reached from 1 by exponentials.

In [13], every unit vector is a turned basic one.

```
def turn_factor(a, b, along_a, along_b):
    if ETA[a] * ETA[b] == 1:  # a rotation
        return (a, b, float(np.arctan2(-ETA[a] * along_b, along_a)))
    return (a, b, float(np.arcsinh(-ETA[a] * along_b)))  # a boost
```

`turn_factor` returns the factor (a, b, θ) whose vector matrix carries e_a to the direction of $\text{along}_a\, e_a + \text{along}_b\, e_b$. For a rotation, step (E) gives $\Lambda e_a = \cos\theta\, e_a - \eta_{aa} \sin\theta\, e_b$; `np.arctan2(y, x)` is the angle θ of the point (x, y) in the plane, so that $\cos\theta$ and $\sin\theta$ are x and y divided by the distance $\sqrt{x^2 + y^2}$. With $x = \text{along}_a$ and $y = -\eta_{aa}\text{along}_b$, the vector Λe_a points along $\text{along}_a\, e_a + \text{along}_b\, e_b$. For a boost, $\Lambda e_a = \cosh\theta\, e_a - \eta_{aa} \sinh\theta\, e_b$; with $\sinh\theta = -\eta_{aa}\text{along}_b$ (`np.arcsinh` is the inverse of sinh) and $\text{along}_a^2 - \text{along}_b^2 = 1$, $\cosh\theta = \sqrt{1 + \text{along}_b^2} = \text{along}_a$.

```
def block_rotation(axis, others, n):
    factors = []
    for k, b in enumerate(others):
        if k < len(others) - 1:  # keep the length of the rest on the axis
            rest = np.sqrt(n[axis] ** 2 + sum(n[o] ** 2 for o in others[k + 1:]))
        else:  # the last rotation leaves exactly n_axis on the axis
            rest = n[axis]
        factors.append(turn_factor(axis, b, rest, n[b]))
    return factors
```

`block_rotation` returns three rotations in the planes (axis, first other), (axis, second other), (axis, third other) that carry e_{axis} to the unit vector n of its block (`n` is a dictionary from direction names to components). The first rotation puts the component n_b on the first other direction and leaves on the axis the length of everything that is still to come, $\sqrt{n_{\text{axis}}^2 + n_{b_2}^2 + n_{b_3}^2}$; each later rotation acts only on what is left on the axis; the last one leaves exactly n_{axis}, which may be negative.

```
def carry(v):
    part = {x: float(v[COORDS.index(x)]) for x in COORDS}
    sigma = np.sqrt(sum(part[x] ** 2 for x in SPACE))  # length of the space part
    tau = np.sqrt(sum(part[x] ** 2 for x in TIME))  # length of the time part
    space_turn = block_rotation("x0", ["x1", "x2", "x3"],
                                {x: part[x] / sigma for x in SPACE}) if sigma else []
    time_turn = block_rotation("x4", ["x5", "x6", "x7"],
                               {x: part[x] / tau for x in TIME}) if tau else []
    if metric_product(v, v) > 0:  # space-like: from e_x0
        return [turn_factor("x0", "x4", sigma, tau)] + time_turn + space_turn, "x0"
    return [turn_factor("x4", "x0", tau, sigma)] + space_turn + time_turn, "x4"
```

`carry(v)` is the construction of step (I). `part` holds the eight components by name; `sigma` and `tau` are the lengths $|\sigma|$ and $|\tau|$ of the space part and the time part. `space_turn` turns e_{x0} into $\sigma/|\sigma|$ and `time_turn` turns e_{x4} into $\tau/|\tau|$ (an empty list when that part is zero; `if sigma else []` uses that the number 0 counts as false). For a space-like v the factors are the boost in $(x0, x4)$, then the time rotations, then the space rotations, and the starting direction is $x0$; for a time-like v the boost in $(x4, x0)$, then the space rotations, then the time rotations, starting from $x4$. The function returns the list of factors (the first acts first) together with the starting direction.

```
def random_unit_vector():
    while True:
        w = rng.normal(size=8)  # eight numbers from the normal distribution
        q = metric_product(w, w)
        if abs(q) >= 0.5:
            return w / np.sqrt(abs(q))
```

A random unit vector: eight numbers are drawn from the normal distribution (the bell curve centred at 0), and the vector is kept only when $|\eta(w, w)| \geq 0.5$ (so that it is not nearly null); `while True` repeats until that happens. Dividing by $\sqrt{|\eta(w, w)|}$ makes $\eta = +1$ or -1.

```
starts = {"x0": 0, "x4": 0}  # how many space-like and time-like vectors
carry_ok, most_factors = True, 0
```

```
for _ in range(40):
    v = random_unit_vector()
    factors, e = carry(v)
    starts[e] += 1
    most_factors = max(most_factors, len(factors))
    h = compose(factors)
    carry_ok &= (np.allclose(vector_matrix(h)[:, COORDS.index(e)], v, atol=1e-12)
                 and np.allclose(h @ gamma[e] @ np.linalg.inv(h), gamma_of(v),
                                 atol=1e-12))
say(f"space-like vectors: {starts['x0']}; time-like vectors: {starts['x4']}; "
    f"at most {most_factors} exponentials per vector")
check(carry_ok and starts["x0"] > 0 and starts["x4"] > 0 and most_factors <= 7,
      "for 40 random unit vectors v: gamma(v) = h gamma^(e) h^-1 with h a product "
      "of at most 7 exponentials and e = x0 or x4")
```

For 40 random unit vectors the cell builds h, checks that column e of its vector matrix is v and that $h\gamma^e h^{-1} = \gamma(v)$ as 16×16 matrices, and counts the space-like and time-like vectors and the largest number of factors. The printed line shows 24 space-like and 16 time-like vectors and at most 7 factors.

In [14], the construction at work.

```
examples = [random_unit_vector() for _ in range(6)]
space_example = next(v for v in examples if metric_product(v, v) > 0)
time_example = next(v for v in examples if metric_product(v, v) < 0)
line_colors = ["#2a78d6", "#eb6834", "#1baf7a", "#4a3aa7", "#e34948", "#eda100",
               "#52514e", "#9e9c98"]
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.6), sharey=True)
steps_ok = True
```

Six more random unit vectors are drawn; `next(...)` takes the first space-like and the first time-like one among them. Eight colours, one per direction, and two pictures that share the vertical axis (`sharey=True`).

```
for ax, v in zip(axes, [space_example, time_example]):
    factors, e = carry(v)
    moving = [E8[COORDS.index(e)]]  # the vector after 0, 1, ..., 7 steps
    for a, b, theta in factors:
        moving.append(vector_matrix(exponential(a, b, theta)) @ moving[-1])
    moving = np.array(moving)
    steps_ok &= np.allclose([metric_product(m, m) for m in moving], ETA[e])
    steps_ok &= np.allclose(moving[-1], v, atol=1e-12)
    if e == "x0":
        for a, b, theta in factors:
            say(f"    factor exp(theta S^({a} {b})), theta = {theta:+.4f}")
```

For each example the moving vector starts at e_{x0} or e_{x4}, and each factor's vector matrix is applied to the latest vector (`moving[-1]` is the last element of the list). The cell checks that the metric product stays η_{ee} at every step and that the last vector is v, and for the space-like example it prints the seven factors with their angles to four decimals.

```
    for i, x in enumerate(COORDS):
        ax.plot(range(len(moving)), moving[:, i], "o-", color=line_colors[i],
                linewidth=1.5, markersize=4, label=x)
        ax.plot([len(moving) - 0.6], [v[i]], "D", color=line_colors[i],
                markersize=6)
    kind = "space-like" if e == "x0" else "time-like"
    ax.set_title(f"a {kind} unit vector, built from $e_{{{e}}}$")
    ax.set_xticks(range(len(moving)))
    ax.set_xlabel("number of exponentials applied")
axes[0].set_ylabel("component of the moving vector")
axes[1].legend(loc="upper center", bbox_to_anchor=(-0.05, -0.15), ncol=8)
check(steps_ok, "in both examples the moving vector keeps eta(w, w) and ends at v")
save_figure(fig, "carrying_vectors",
            ...)
```

Still inside the loop, each of the eight components is drawn against the number of steps, and the target component of v as a diamond (`"D"`) just right of the last step. In `05f_5_carrying_vectors.png` the first step shares the length between $x0$ and $x4$ (a boost), the next three steps fill one block and the last three the other, and every curve ends at its diamond.

In [15], moving a gamma through an exponential.

```
def conjugation_sign(e, a, b):
    return -1 if e in (a, b) else 1

conjugation_ok = all(
    np.allclose(gamma[e] @ exponential(a, b, 0.8) @ np.linalg.inv(gamma[e]),
                exponential(a, b, conjugation_sign(e, a, b) * 0.8), atol=1e-12)
    for e in ("x0", "x4") for a, b in pairs)
check(conjugation_ok, "gamma^e exp(theta S^ab) (gamma^e)^-1 = exp(s theta S^ab), "
      "s = -1 if e is a or b, +1 otherwise")
```

`conjugation_sign` is the sign s of step (J). The check confirms $\gamma^e \exp(\theta S^{ab})(\gamma^e)^{-1} = \exp(s\theta S^{ab})$ for $e = x0$ and $x4$, all 28 planes and $\theta = 0.8$.

In [16], twelve random elements of Pin(4,4).

```
FOUR = {"1": I16, "gamma^(x0)": gamma["x0"], "gamma^(x4)": gamma["x4"],
        "gamma^(x0) gamma^(x4)": gamma["x0"] @ gamma["x4"]}

def evaluate(word):
    g = np.eye(16)
    for item in word:
        if item[0] == "exp":
            g = g @ exponential(*item[1:])
        else:
            g = g @ gamma[item[1]]
    return g
```

A **word** is a list of items in the order of the matrix product: an exponential `("exp", a, b, theta)` or a gamma `("gamma", e)`. `evaluate` multiplies the items from left to right (`item[1:]` is

the item without its first entry, unpacked into the arguments of `exponential`). `FOUR` holds the four words as matrices.

```
def word_of(v):
    factors, e = carry(v)
    h_word = [("exp", a, b, th) for a, b, th in reversed(factors)]  # E_n ... E_1
    h_inverse = [("exp", a, b, -th) for a, b, th in factors]  # E_1^-1 ... E_n^-1
    return h_word + [("gamma", e)] + h_inverse
```

`word_of(v)` writes $\gamma(v) = h\gamma^e h^{-1}$ as a word. Since the first factor acts first, $h = E_n \cdots E_1$, which is the list of factors reversed; $h^{-1} = E_1^{-1} \cdots E_n^{-1}$, each with the opposite angle.

```
def move_gammas_right(word):
    exponentials, waiting = [], []  # waiting: the gammas moved to the right so far
    for item in word:
        if item[0] == "gamma":
            waiting.append(item[1])
        else:  # this exponential is moved to the left of all waiting gammas
            _, a, b, theta = item
            s = 1
            for e in waiting:
                s *= conjugation_sign(e, a, b)
            exponentials.append(("exp", a, b, s * theta))
    return exponentials, waiting
```

`move_gammas_right` reads the word from left to right. A gamma is put on the list `waiting`. An exponential that comes after waiting gammas is moved to their left; by step (J) each gamma it passes multiplies its angle by the sign s of that gamma. The result is the list of exponentials followed by the list of gammas, which as a word equals the original word.

```
def reduce_gammas(waiting):
    product = I16
    for e in waiting:
        product = product @ gamma[e]
    for name, w in FOUR.items():
        if np.array_equal(product, w):
            return 1, name
        if np.array_equal(product, -w):
            return -1, name
    raise ValueError("the product of the gammas is not one of the four words")
```

`reduce_gammas` multiplies the waiting gammas and finds which of the four words it equals, with which sign; if it were none of them (impossible by step (J)), the notebook would stop with an error.

```
decomposition_ok = True
for number in range(12):
    k = 1 + number % 6  # the number of unit vectors
    vectors = [random_unit_vector() for _ in range(k)]
    g = np.eye(16)
```

```
    word = []
    for v in vectors:
        g = g @ gamma_of(v)
        word += word_of(v)
    size = np.max(np.abs(g))  # for relative differences
    exponentials, waiting = move_gammas_right(word)
    sign, name = reduce_gammas(waiting)
    if sign == -1:  # -1 = exp(2 pi S^(x1 x2))
        exponentials.append(("exp", "x1", "x2", 2 * np.pi))
    rebuilt = evaluate(exponentials) @ FOUR[name]
```

Twelve elements are made from $k = 1, \ldots, 6$ random unit vectors (twice each; `number % 6` is the remainder of the number divided by 6). For each, the product g and its word are built, the gammas are moved to the right and reduced, a sign -1 is replaced by the exponential $\exp(2\pi S^{(x1)(x2)}) = -1$, and the decomposition is multiplied out again as `rebuilt`.

```
    same_pattern = (pattern(vector_matrix(g, odd=k % 2 == 1))
                    == pattern(vector_matrix(FOUR[name].astype(float), WORDS[name][1])))
    decomposition_ok &= (np.max(np.abs(evaluate(word) - g)) < 1e-9 * size
                         and np.max(np.abs(rebuilt - g)) < 1e-9 * size
                         and same_pattern and WORDS[name][1] == (k % 2 == 1))
    plural = "s" if k > 1 else " "  # "1 unit vector", "2 unit vectors"
    say(f"element {number + 1:2d}: {k} unit vector{plural} = {len(exponentials):2d} "
        f"exponentials times {name}")
check(decomposition_ok, "12 random elements of Pin(4,4): each is a product of "
      "exponentials times one of 1, gamma^(x0), gamma^(x4), gamma^(x0) gamma^(x4), "
      "with the matching sign pattern")
```

The checks for each element: the word equals g, the decomposition equals g (both to a relative accuracy of 10^{-9}, measured against the largest entry `size` of g, because the entries of g can be large), g has the sign pattern of its word, and the word is odd exactly when k is odd. The twelve printed lines show, for example, that one unit vector becomes 14 exponentials times $\gamma^{(x4)}$ (seven for h and seven for h^{-1}; both elements made of one vector happen to be time-like), that an odd number of vectors always ends with an odd word ($\gamma^{(x0)}$ or $\gamma^{(x4)}$) and an even number with an even word, and that the two elements made of two vectors end with the two different even words, 1 and $\gamma^{(x0)}\gamma^{(x4)}$.

In [17], the spans.

```
formula_ok = all(
    np.allclose(exponential(a, b, np.pi), gamma[a] @ gamma[b], atol=1e-12)
    if ETA[a] * ETA[b] == 1 else
    np.allclose((exponential(a, b, 0.8) - exponential(a, b, -0.8))
                / (2 * np.sinh(0.4)), gamma[a] @ gamma[b], atol=1e-12)
    for a, b in pairs)
check(formula_ok, "exp(pi S^ab) = gamma^a gamma^b for the rotations and "
      "(exp(theta S^ab) - exp(-theta S^ab)) / (2 sinh(theta/2)) = gamma^a gamma^b "
      "for the boosts")
```

The two formulas of the last paragraph of Section 5.23 are checked for all 28 planes (for the boosts with $\theta = 0.8$, so that $2\sinh\frac{\theta}{2} = 2\sinh 0.4$).

```
spin0_elements = [compose(random_factors(6)) for _ in range(170)]
four_words = list(FOUR.values())
pin_elements = [compose(random_factors(6)) @ four_words[k % 4] for k in range(300)]

def rank_curve(elements):
    ranks = []
    for n in range(1, len(elements) + 1):
        rows = np.array([g.reshape(256) for g in elements[:n]])
        singular = np.linalg.svd(rows, compute_uv=False)
        ranks.append(int(np.sum(singular > 1e-9 * singular[0])))
    return ranks
```

170 random products of six exponentials, and 300 random elements of all four pieces (`k % 4` runs through the four words). `rank_curve` computes, for $n = 1, 2, \ldots$, the rank of the first n elements written as rows. It uses the **singular values** of the array of rows (`np.linalg.svd(..., compute_uv=False)`): the square roots of the eigenvalues of $A^T A$ for the array A, sorted from the largest. By the argument of Section 5.13 the number of nonzero ones is the rank; here a singular value counts as nonzero when it is above 10^{-9} times the largest.

```
ranks_spin0, ranks_pin = rank_curve(spin0_elements), rank_curve(pin_elements)
block_diagonal = all(not g[:8, 8:].any() and not g[8:, :8].any()
                     for g in spin0_elements)

                 and recorded("python", "even_products_span_M8_plus_M8"),
                 "the products of exponentials are block diagonal and span 128 "
                 "dimensions, as the 128 even Clifford products",
                 record=record_of("python", "even_products_span_M8_plus_M8"))
check_reproduces(ranks_pin == [min(n, 256) for n in range(1, 301)]
                 and recorded("python", "clifford_products_span_M16"),
                 "the elements of Pin(4,4) span all 256 dimensions of the 16 x 16 "
                 "matrices",
                 record=record_of("python", "clifford_products_span_M16"))
```

The two RESULT lines print the final ranks, 128 and 256. The checks require that each new element raised the rank by one until it stopped at 128 (for the products of exponentials, which are also all block diagonal) and at 256 (for Pin(4,4)): the numbers that the record found for the even and for all products of different gammas.

In [18], the picture of the spans.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
ax.plot(range(1, 171), ranks_spin0, color="#2a78d6", linewidth=2.5,
        label=r"products of exponentials ($\mathrm{Spin}_0(4,4)$)")
ax.plot(range(1, 301), ranks_pin, color="#eb6834", linewidth=2, linestyle="--",
        label="elements of Pin(4,4) (all four pieces)")
ax.axhline(128, color="#2a78d6", linewidth=0.8, linestyle=":")
ax.axhline(256, color="#eb6834", linewidth=0.8, linestyle=":")
```

```
ax.set_xlabel("number $n$ of random group elements")
ax.set_ylabel("rank of the first $n$ elements")
ax.set_yticks([0, 64, 128, 192, 256])
ax.set_title("The span of the group elements")
ax.legend(loc="lower right")
save_figure(fig, "span_ranks",
            ...)
```

The two rank curves and dotted lines at 128 and 256. In `05f_6_span_ranks.png` both curves rise along the diagonal and then stop flat, the solid one at 128 and the dashed one at 256.

In [19], the last check.

```
FIGURES = ["05f_1_generator_matrices.png", "05f_2_two_unit_vectors.png",
           "05f_3_four_pieces.png", "05f_4_paths_and_band.png",
           "05f_5_carrying_vectors.png", "05f_6_span_ranks.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the six figure files of notebook 05f exist")
all_checks_passed()
```

The last line reads ALL 24 CHECKS PASSED (notebook 05f): one each in In [2] and In [3], three in In [4], one in In [5], two in In [6], one in In [7], two in In [8], one in In [9], three in In [10], one each in In [12] to In [16], three in In [17] and one in In [19]. Six of them reproduce recorded checks (In [2], In [3], the first and the third of In [4], and the last two of In [17]); the other eighteen are the notebook's own computations.

5.28 Charge conjugation is a matrix

The question. Every known particle has an **antiparticle** with the same mass and the opposite charge; the positron is the antiparticle of the electron. In a field theory the step from a solution to its antiparticle solution is made by a map called **charge conjugation**: it turns every solution of the field equation into another solution whose charge density has the opposite sign. In the usual four-dimensional Dirac theory this map contains a complex conjugation of the components together with a fixed matrix. In the author's theory one fact changes the picture: the eight gammas are real (Section 5.2). Take a **real** field, one whose 16 components are real numbers at every point, so that $\Psi^* = \Psi$. On such a field the complex conjugation $\Psi \to \Psi^*$ changes nothing at all: it is the identity map. A map that changes nothing cannot exchange matter and antimatter. So whatever charge conjugation is in this theory, it must be made by a **matrix**. This section derives the condition that such a matrix must obey together with every gamma, takes that condition as the definition of a charge-conjugation matrix (as the Revision record does), and finds every matrix that obeys it. The answer (Theorem CC below) is: exactly two, up to a factor, $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$. The Revision record that this section follows is the lead check `Revision/lead_checks/charge_conjugation_and_u1.py` with its report `Revision/lead_checks/reports/charge-conjugation-and-u1.json` (12 of 12 checks passed); Notebook 05c reproduces ten of its checks.

The field equation. Chapter 7 derives, from the Lagrangian of the Revision record, the field equation of both fields of the author,

$$\gamma^\mu D_\mu \Psi = V \Psi, \qquad V = m + U'(S).$$

Here the index μ runs over the eight coordinates and a repeated index is summed (the **sum convention** of Chapter 1); $\gamma^\mu = e^\mu{}_a \gamma^a$ are the gammas of the curved space, made from the constant gammas γ^a with the **vielbein** $e^\mu{}_a$, a set of real factors that Chapter 6 computes from the author's metric; $D_\mu = \partial_\mu + \Omega_\mu$ is the **covariant derivative**, the partial derivative ∂_μ along the coordinate μ plus a 16×16 matrix Ω_μ, the **spin connection**, which is a combination of the generators S^{ab} with real coefficients (Chapter 6); m is the mass; $U(S)$ is the self-interaction, a function of the scalar $S = \bar\Psi\Psi$, with derivative $U'(S)$; for the record's choice $U = \frac{\lambda}{2}S^2$ one has $V = m + \lambda S$. Only one property of this equation is needed now: **every matrix in it is real.** The gammas are real (Section 5.2), the vielbein factors are real, the number V is real, and the Revision record checks that every entry of every Ω_μ is a real expression (check `spinor_connection_real` of the lead report).

What we want. We look for a constant 16×16 matrix $\mathcal{C}$ such that, whenever Ψ solves the field equation, the column

$$\Psi^c = \mathcal{C}\,\bar\Psi^T$$

solves the field equation of the same form, either with the same V (**same mass**) or with $-V$ (**mass reversed**). Here $\bar\Psi = \Psi^\dagger C$ is the Dirac adjoint of Section 5.4, a row, and $\bar\Psi^T$ is that row turned into a column. This wish is not yet the definition; the definition comes after Step 4, below.

From the wish to an equation for a matrix, line by line. First the column $\bar\Psi^T$:

$$\bar\Psi^T = (\Psi^\dagger C)^T = C^T(\Psi^\dagger)^T = C\Psi^*.$$

The first step is the definition of $\bar\Psi$; the second is the rule $(XY)^T = Y^T X^T$; the third uses that the transpose of the row $\Psi^\dagger$ is the column Ψ^* of the conjugated components, and $C^T = C$ (property (C2) of Section 5.4). So $\Psi^c = \mathcal{C}C\Psi^*$. Write $M = \mathcal{C}C$; then $\Psi^c = M\Psi^*$, and since $CC = 1$ (C3), $\mathcal{C} = MC$.

- Step 1 (conjugate the equation). The complex conjugate of a product is the product of the complex conjugates, a real factor is its own conjugate, and the derivative of the conjugate is the conjugate of the derivative (the coordinates are real). So the conjugate of $\gamma^\mu D_\mu \Psi = V\Psi$ is $\gamma^\mu D_\mu \Psi^* = V\Psi^*$: **the column Ψ^* solves the same equation.**
- Step 2 (multiply by a constant matrix). Multiply from the left by M: $M\gamma^\mu D_\mu \Psi^* = V\,M\Psi^*$; the number V may stand on either side of M.
- Step 3 (a condition on M that is enough). Suppose that, with one sign s ($+1$ or -1) for all eight directions,

$$M\gamma^a = s\,\gamma^a M \qquad \text{for } a = x0, \ldots, x7.$$

Then $M\gamma^\mu = \sum_a e^\mu{}_a M\gamma^a = s\,\gamma^\mu M$, because the vielbein factors are numbers. M commutes with every product of two gammas: $M\gamma^a\gamma^b = s\,\gamma^a M\gamma^b = s^2\,\gamma^a\gamma^b M = \gamma^a\gamma^b M$ (the condition used twice, then $s^2 = 1$). The spin connection is a combination of the $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$, so $M\Omega_\mu = \Omega_\mu M$; and a constant matrix commutes with a derivative, $M\partial_\mu = \partial_\mu M$. Hence $MD_\mu = D_\mu M$.

- Step 4 (the new field). With Step 3, $M\gamma^\mu D_\mu \Psi^* = s\,\gamma^\mu M D_\mu \Psi^* = s\,\gamma^\mu D_\mu (M\Psi^*)$. So the equation of Step 2 reads $s\,\gamma^\mu D_\mu (M\Psi^*) = V\,(M\Psi^*)$. Multiplying by s and using $s^2 = 1$:

$$\gamma^\mu D_\mu (M\Psi^*) = s\,V\,(M\Psi^*).$$

The new field $M\Psi^*$ solves the equation with V when $s = +1$ and with $-V$ when $s = -1$. Because the gammas are real, $(\gamma^a)^* = \gamma^a$, and the condition of Step 3 can be written $M(\gamma^a)^* = s\,\gamma^a M$; this is the form that the Revision record solves (it would also be the right form for complex gammas). One more remark about $V = m + \lambda S$, which depends on the field through S: Section 5.29 shows that for commuting components both matrices found below give a new field with the same S as Ψ. Then $sV = s\,m + s\,\lambda S$, so the new field solves the field equation with the parameters (m, λ) when $s = +1$ and $(-m, -\lambda)$ when $s = -1$. For a free field ($\lambda = 0$) only the mass matters. (For anticommuting components the table of Section 5.29 shows that the scalar changes its sign; this affects only the self-interaction term, and Section 5.34 treats the quantised field.)

Definition. A **charge-conjugation matrix** is a constant 16×16 matrix $\mathcal{C}$ for which the matrix $M = \mathcal{C}C$ obeys the **intertwiner condition**

$$M(\gamma^a)^* = s\,\gamma^a M \qquad \text{for } a = x0, \ldots, x7,$$

with one sign s ($+1$ or -1) for all eight directions. It is called **same mass** when $s = +1$ and **mass reversed** when $s = -1$. (The name: in the words of Section 5.11, M is an intertwiner from the list of the conjugated gammas $(\gamma^a)^*$ to the list of the matrices $s\,\gamma^a$.) This is the definition of the Revision record: its checks `intertwiners_same_mass` and `intertwiners_reversed_mass` solve exactly this condition. Steps 1 to 4 prove that every charge-conjugation matrix does what we wanted: for every solution Ψ, the column $\Psi^c = M\Psi^*$ solves the field equation with sV.

Why the definition is the condition and not the wish. Steps 1 to 4 show that the condition is enough for the wish. The converse is not true in general: a matrix can turn every solution into a solution without obeying the condition. Here is an example, line by line, for $V = 0$ (mass $m = 0$ and no self-interaction, $\lambda = 0$), a case that the field equation allows. Take $M = P_- = \frac{1}{2}(1 - \Gamma)$, the chiral projector of Section 5.5, so that $\mathcal{C} = P_- C$.

1. P_- is a combination of 1 and of Γ, a product of eight gammas, so it is even, and by (X3) it commutes with every S^{ab}, hence with every Ω_μ; as a constant matrix it commutes with every ∂_μ. So $P_- D_\mu = D_\mu P_-$.
2. Section 5.5 proved $\gamma^a P_- = P_+ \gamma^a$ for every a. Multiplying by the vielbein numbers $e^\mu{}_a$ and adding over a gives $\gamma^\mu P_- = P_+ \gamma^\mu$.
3. For every solution Ψ: $\gamma^\mu D_\mu (P_- \Psi^*) = \gamma^\mu P_- D_\mu \Psi^* = P_+ \gamma^\mu D_\mu \Psi^* = P_+ (V \Psi^*) = 0$. The first step is line 1, the second is line 2, the third is Step 1 (the column Ψ^* solves the equation), the fourth is $V = 0$.

So $P_-\Psi^*$ solves the equation with $V = 0$, which is also $-V$: the matrix $P_- C$ fulfils the wish. It does not obey the condition, for either sign. Proof: Section 5.5 also gives $P_- \gamma^a = \gamma^a P_+$ (the same rule with the halves exchanged). If $P_- \gamma^a = s\,\gamma^a P_-$ held, then $\gamma^a P_+ = s\,\gamma^a P_-$; multiplying from the

left by $\eta_{aa}\gamma^a$ and using $\eta_{aa}\gamma^a\gamma^a = \eta_{aa}\eta_{aa}1 = 1$ gives $P_+ = s\,P_-$; multiplying this from the right by P_+ gives $P_+P_+ = s\,P_-P_+$, that is $P_+ = 0$ (because $P_+P_+ = P_+$ and $P_-P_+ = 0$, Section 5.5). But $P_+ = \mathrm{diag}(0, 1_8)$ is not zero: a contradiction. So with the wish as the definition, the count "exactly two" of Theorem CC would be false for $V = 0$; with the condition as the definition, it is proved below. For $V \neq 0$ this book does not study whether some matrix outside the condition fulfils the wish in the author's metric (OPEN); nothing in this chapter depends on that question, because the Revision record and this chapter use the condition.

Theorem CC (the two charge-conjugation matrices).

- (a) The solutions M of $M(\gamma^a)^* = +\gamma^a M$ for all a are the multiples of 1; the solutions of $M(\gamma^a)^* = -\gamma^a M$ for all a are the multiples of Γ.
- (b) Hence, by the definition above, there are exactly two charge-conjugation matrices, up to a factor: $\mathcal{C}_+ = C$ (same mass), with $\Psi^c = \mathcal{C}_+\bar{\Psi}^T = \Psi^*$, and $\mathcal{C}_- = \Gamma C$ (mass reversed), with $\Psi^c = \mathcal{C}_-\bar{\Psi}^T = \Gamma\Psi^*$. By Steps 1 to 4, the first maps every solution to a solution with V, the second to a solution with $-V$.
- (c) They obey $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$ and $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$ for every a; both are real and symmetric, and $\mathcal{C}_+\mathcal{C}_+ = \mathcal{C}_-\mathcal{C}_- = 1$.

Proof of (a). The gammas are real, so the condition reads $M\gamma^a = s\,\gamma^a M$. For $s = +1$, M commutes with all eight gammas, and by Theorem P of Section 5.13 it is a multiple of 1. For $s = -1$, M anticommutes with every gamma. Then ΓM commutes with every gamma:

$$\gamma^a(\Gamma M) = -\Gamma\gamma^a M = -\Gamma(-M\gamma^a) = (\Gamma M)\gamma^a.$$

The first step is (X2) of Section 5.5 (Γ anticommutes with every gamma); the second is the condition, read as $\gamma^a M = -M\gamma^a$; the third collects the two signs. By Theorem P, $\Gamma M = \lambda 1$ for some number λ; multiplying from the left by Γ and using $\Gamma\Gamma = 1$ (X1) gives $M = \lambda\Gamma$. Conversely, 1 commutes with every gamma and Γ anticommutes with every gamma (X2), so both are solutions. The two solution spaces are therefore one-dimensional, spanned by 1 and by Γ.

Proof of (b). By the definition, $\mathcal{C}$ is a charge-conjugation matrix exactly when $M = \mathcal{C}C$ solves one of the two conditions of (a); then $\mathcal{C} = MC$ (above), and by (a) M is a multiple of 1 or of Γ. $M = 1$ gives $\mathcal{C}_+ = C$ and $\Psi^c = 1\,\Psi^* = \Psi^*$; $M = \Gamma$ gives $\mathcal{C}_- = \Gamma C$ and $\Psi^c = \Gamma\Psi^*$.

Proof of (c). For $\mathcal{C}_+ = C$, with $C^{-1} = C$ (C3), $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = C\gamma^a C = -(\gamma^a)^T$ by (C5). For $\mathcal{C}_-$, the inverse of a product is the product of the inverses in the reverse order, so $\mathcal{C}_-^{-1} = C^{-1}\Gamma^{-1} = C\Gamma$ by (C3) and (X1). Then

$$\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = C\Gamma\gamma^a\Gamma C = C(-\gamma^a\Gamma)\Gamma C = -C\gamma^a C = +(\gamma^a)^T.$$

The second step is (X2), the third is $\Gamma\Gamma = 1$ (X1), the fourth is (C5). Both matrices are products of real matrices, hence real. Symmetry: $C^T = C$ is (C2); $(\Gamma C)^T = C^T\Gamma^T = C\Gamma = \Gamma C$ by $(XY)^T = Y^T X^T$, (C2), (X6) and (X5). Squares: $CC = 1$ is (C3); $\Gamma C\Gamma C = \Gamma\Gamma CC = 1$ by (X5), (X1) and (C3). □

The shape of $\mathcal{C}_-$. $\Gamma = \mathrm{diag}(-1_8, 1_8)$ and $C = \mathrm{diag}(-\sigma, \sigma)$ (Sections 5.4 and 5.5), so $\Gamma C = \mathrm{diag}(\sigma, \sigma)$: multiplying by Γ from the left reverses the sign of the rows 1 to 8 (the block rule of Section 5.5). The table of Section 5.6 lists ΓC next to C.

The same two matrices from the transposition rules. Many books define a charge-conjugation matrix by the condition $\mathcal{C}^{-1}\gamma^a\mathcal{C} = \zeta(\gamma^a)^T$ with a sign ζ, that is $\gamma^a\mathcal{C} = \zeta\,\mathcal{C}(\gamma^a)^T$. Solving this directly gives the same two matrices: the solutions X of $\gamma^a X = \zeta X(\gamma^a)^T$ (all a) are the multiples of C for $\zeta = -1$ and of ΓC for $\zeta = +1$. Proof: (C5) with $C^{-1} = C$ says $(\gamma^a)^T = -C\gamma^a C$, so the equation reads $\gamma^a X = -\zeta XC\gamma^a C$; multiplying from the right by C (and $CC = 1$) gives $\gamma^a(XC) = -\zeta(XC)\gamma^a$. By part (a), $XC = \lambda 1$ when $-\zeta = +1$ and $XC = \lambda\Gamma$ when $-\zeta = -1$; multiplying from the right by C gives $X = \lambda C$ or $X = \lambda\Gamma C$.

What $\mathcal{C}_+$ does to a real field. For every field $\mathcal{C}_+\bar{\Psi}^T$ is the column Ψ^*. For a complex field this column differs from Ψ; for a real field it is Ψ itself. So the same-mass charge conjugation leaves every real field unchanged: a real field is its own $\mathcal{C}_+$ conjugate. Section 5.29 shows what this means for the charge, and which real map is not trivial.

A worked example: the free field along the time. Take flat space, no self-interaction, and a field that depends only on the time $x4$. The field equation keeps only the term with $\mu = x4$, and in flat space $\gamma^{(x4)}$ is the constant gamma of $x4$:

$$\gamma^{(x4)}\frac{d\Psi}{dx4} = m\Psi.$$

Multiplying from the left by $-\gamma^{(x4)}$ and using $\gamma^{(x4)}\gamma^{(x4)} = -1$ gives $d\Psi/dx4 = -m\gamma^{(x4)}\Psi$. For any constant column Ψ_0 the column

$$\Psi(x4) = \cos(m\,x4)\,\Psi_0 - \sin(m\,x4)\,\gamma^{(x4)}\Psi_0$$

solves it. Check, line by line: by the chain rule, $d\cos(m\,x4)/dx4 = -m\sin(m\,x4)$ and $d\sin(m\,x4)/dx4 = m\cos(m\,x4)$, so

$$\frac{d\Psi}{dx4} = -m\sin(m\,x4)\,\Psi_0 - m\cos(m\,x4)\,\gamma^{(x4)}\Psi_0;$$

multiplying from the left by $\gamma^{(x4)}$ and using $\gamma^{(x4)}\gamma^{(x4)} = -1$ in the second term,

$$\gamma^{(x4)}\frac{d\Psi}{dx4} = -m\sin(m\,x4)\,\gamma^{(x4)}\Psi_0 + m\cos(m\,x4)\,\Psi_0 = m\Psi.$$

Now the two conjugates. Since cos, sin and $\gamma^{(x4)}$ are real,

$$\Psi^*(x4) = \cos(m\,x4)\,\Psi_0^* - \sin(m\,x4)\,\gamma^{(x4)}\Psi_0^*:$$

the same formula with the starting column Ψ_0^*, so Ψ^* solves the equation with the **same mass** m. For the other, put $\Phi_0 = \Gamma\Psi_0^*$ and use $\Gamma\gamma^{(x4)} = -\gamma^{(x4)}\Gamma$ (X2):

$$\Gamma\Psi^*(x4) = \cos(m\,x4)\,\Phi_0 + \sin(m\,x4)\,\gamma^{(x4)}\Phi_0 = \cos(-m\,x4)\,\Phi_0 - \sin(-m\,x4)\,\gamma^{(x4)}\Phi_0,$$

where the last step uses $\cos(-y) = \cos y$ and $\sin(-y) = -\sin y$. This is the solution formula with m replaced by $-m$: $\Gamma\Psi^*$ solves the equation with the **mass reversed**. Notebook 05c checks both statements exactly with sympy, for a general mass m, and numerically on 801 time points (figures 3 and 4 of the notebook).

5.29 The bilinears, the reality conditions and real fields

Anticommuting numbers. The components of the field dirac16complex00 are ordinary (complex) numbers, which **commute**: $\Psi_r\Psi_c = \Psi_c\Psi_r$. The components of dirac16complex are **anticommuting** numbers, also called **Grassmann numbers** after the mathematician who introduced them: exchanging two of them in a product costs a sign, $\Psi_r\Psi_c = -\Psi_c\Psi_r$, and in particular $\Psi_r\Psi_r = -\Psi_r\Psi_r$, so $\Psi_r\Psi_r = 0$. Chapter 7 builds them from zero. Here only the exchange rule is used, and the conjugated components Ψ_r^* are treated as further anticommuting numbers. Write $\epsilon = +1$ for commuting and $\epsilon = -1$ for anticommuting components: exchanging two components costs the factor ϵ.

How a bilinear changes, line by line. For a fixed matrix K the **bilinear** $\Psi^\dagger K\Psi = \sum_{r,c}\Psi_r^* K_{rc}\Psi_c$ is a single number. Replace Ψ by $\Psi' = M\Psi^*$ with a real matrix M.

1. $(\Psi')^\dagger = (M\Psi^*)^\dagger = (\Psi^*)^\dagger M^\dagger = \Psi^T M^\dagger$, by the rule $(XY)^\dagger = Y^\dagger X^\dagger$ and because conjugating twice gives the number back. So $\Psi'^\dagger K\Psi' = \Psi^T M^\dagger K M\Psi^* = \sum_{r,c}\Psi_r\,(M^\dagger KM)_{rc}\,\Psi_c^*$.
2. Exchange the two factors Ψ_r and Ψ_c^*; this costs the factor ϵ: $\sum_{r,c}\epsilon\,\Psi_c^*\,(M^\dagger KM)_{rc}\,\Psi_r$.
3. Rename the summation letters, $r \leftrightarrow c$: $\sum_{r,c}\Psi_r^*\,\epsilon(M^\dagger KM)_{cr}\,\Psi_c = \Psi^\dagger K'\Psi$ with $K' = \epsilon\,(M^\dagger KM)^T$.

So **the bilinear with the matrix K turns into the bilinear with the matrix $K' = \epsilon(M^\dagger KM)^T$.** If $K' = +K$ the bilinear is kept, if $K' = -K$ it is reversed.

The signs of S and J. The scalar has $K = C$, the currents $K = -iC\gamma^a$ (Section 5.4). The two maps have $M = 1$ ($\mathcal{C}_+$) and $M = \Gamma$ ($\mathcal{C}_-$); both are real and symmetric, so $M^\dagger = M$.

- $\mathcal{C}_+$, scalar: $K' = \epsilon C^T = \epsilon C$ by (C2). So $S \to \epsilon S$.
- $\mathcal{C}_+$, currents: $(-iC\gamma^a)^T = -i(C\gamma^a)^T = -i(-C\gamma^a) = iC\gamma^a$ by (C4), so $K' = \epsilon\,iC\gamma^a = -\epsilon K$. So $J^a \to -\epsilon J^a$.
- $\mathcal{C}_-$, scalar: $\Gamma C\Gamma = \Gamma^T C\Gamma = C$ by (X6) and (X7), so $K' = \epsilon C^T = \epsilon C$. So $S \to \epsilon S$.
- $\mathcal{C}_-$, currents: $\Gamma(-iC\gamma^a)\Gamma = -i\,\Gamma^T C\gamma^a\Gamma = -i(-C\gamma^a) = iC\gamma^a$ by (X6) and (X8), and its transpose is $i(C\gamma^a)^T = -iC\gamma^a = K$ by (C4). So $K' = \epsilon K$ and $J^a \to \epsilon J^a$.

map	**components**	S **becomes**	**every** J^a **becomes**
$\mathcal{C}_+$ $(M = 1)$	commuting $(\epsilon = +1)$	$+S$	$-J^a$
$\mathcal{C}_+$ $(M = 1)$	anticommuting $(\epsilon = -1)$	$-S$	$+J^a$
$\mathcal{C}_-$ $(M = \Gamma)$	commuting $(\epsilon = +1)$	$+S$	$+J^a$
$\mathcal{C}_-$ $(M = \Gamma)$	anticommuting $(\epsilon = -1)$	$-S$	$-J^a$

This is the table that the Revision record measured (check `bilinears_under_charge_conjugation`, the part of its detail text after the word measured); Notebook 05c reproduces it exactly. For

the anticommuting rows the table is a statement about classical Grassmann components. For the quantised field the question is decided by an operator computation, which Section 5.34 carries out: after normal ordering the quantised field has exactly the signs of the anticommuting rows. The detail text of the record's check says the same: normal ordering adds no sign, because it subtracts the vacuum value, which is a number (the record makes no Fock-space computation; Notebook 05e makes one). An earlier version of that detail text said instead that normal ordering supplies one more sign for each bilinear; the derivation of Section 5.34 and the computation of Notebook 05e contradicted it, and the record was corrected on 2026-10-08, so the contradiction is resolved.

What the table means for the commuting field. For dirac16complex00, whose components are commuting complex numbers, $\mathcal{C}_+$ keeps the mass and the scalar and reverses every current, in particular the charge density $J^{(x4)} = \Psi^\dagger B \Psi$. So it turns every solution of charge Q into a solution of the same mass and charge $-Q$: it is the antiparticle map of this field. $\mathcal{C}_-$ reverses the mass and keeps the charge. Notebook 05c shows this on the free solution of Section 5.28 with a fixed complex column Ψ_0: the solution has $S = -2$ and $J^{(x4)} = -6$ at every time; Ψ^* has $S = -2$ and $J^{(x4)} = +6$; $\Gamma\Psi^*$ has $S = -2$ and $J^{(x4)} = -6$ (figure 5 of the notebook).

The reality (Majorana) conditions. A field equal to its own conjugate obeys $\Psi = M\Psi^*$; such a requirement is called a **Majorana** or **reality condition**, after the physicist who first used one. Is it a sensible requirement? Take the complex conjugate of the condition, $\Psi^* = M^*\Psi$, and put it back into the condition: $\Psi = MM^*\Psi$. If $MM^* = 1$ this is automatically true, and the condition is called **consistent**; otherwise it forces further conditions on Ψ (possibly $\Psi = 0$). For $M = 1$, $MM^* = 1$: the condition $\Psi = \Psi^*$ says that the field is real. For $M = \Gamma$, $\Gamma\Gamma^* = \Gamma\Gamma = 1$: the condition $\Psi = \Gamma\Psi^*$ says, component by component, $\Psi_r = -\Psi_r^*$ for $r = 1, \ldots, 8$ (where $\Gamma = -1$), so these components are purely imaginary, and $\Psi_r = \Psi_r^*$ for $r = 9, \ldots, 16$, which are real. Both conditions are consistent (record check `majorana_conditions_consistent`).

Do they survive the time evolution? Consistency is a statement about one moment. For the free solution of Section 5.28: if Ψ_0 is real, every factor of the solution is real and the field stays real for ever. If instead $\Psi_0 = \Gamma\Psi_0^*$, then, using $\Gamma\gamma^{(x4)} = -\gamma^{(x4)}\Gamma$ (X2) and $\Gamma\Psi_0^* = \Psi_0$,

$$\Gamma\Psi(x4)^* = \cos(m\,x4)\,\Gamma\Psi_0^* - \sin(m\,x4)\,\Gamma\gamma^{(x4)}\Psi_0^* = \cos(m\,x4)\,\Psi_0 + \sin(m\,x4)\,\gamma^{(x4)}\Psi_0,$$

and subtracting this from $\Psi(x4)$:

$$\Psi(x4) - \Gamma\Psi(x4)^* = -2\sin(m\,x4)\,\gamma^{(x4)}\Psi_0.$$

Its length is $2|\sin(m\,x4)|$ times the length of Ψ_0, because $\gamma^{(x4)}$ is a signed permutation matrix and keeps lengths. So the condition $\Psi = \Gamma\Psi^*$ holds at all times only for $m = 0$. This is what "mass reversed" means: a field equal to its own $\mathcal{C}_-$ image would have to solve the equation with V and with $-V$ at the same time (figure 7 of Notebook 05c).

Real fields. For a real field with commuting components, three facts hold.

- (F1) **The currents vanish.** $J^a = \Psi^\dagger(-iC\gamma^a)\Psi = -i\,\Psi^T A\Psi$ with $A = C\gamma^a$, which is antisymmetric by (C4). For every real column u and every antisymmetric A, $u^TAu = 0$: the number u^TAu equals its own transpose, $u^TAu = (u^TAu)^T = u^TA^Tu = -u^TAu$ (the rule $(XYZ)^T = Z^TY^TX^T$, then $A^T = -A$), and a number equal to minus itself is 0. So a real commuting field carries no current and no charge.

- (F2) $\mathcal{C}_+$ **acts as the identity.** $\Psi^c = \Psi^* = \Psi$: a real field is its own same-mass conjugate.
- (F3) **The real matrix Γ reverses the mass.** The map $\Psi \to \Gamma\Psi$ (no conjugation) takes real fields to real fields. It keeps the scalar, $(\Gamma\Psi)^T C(\Gamma\Psi) = \Psi^T\Gamma^T C\Gamma\Psi = \Psi^T C\Psi$ by (X7), and it reverses every kinetic matrix, $\Gamma^T C\gamma^a\Gamma = -C\gamma^a$ by (X8). In the field equation: Γ commutes with Ω_μ (an even matrix, (X3)) and with ∂_μ, so $\Gamma D_\mu = D_\mu\Gamma$, and Γ anticommutes with every γ^μ; hence $\gamma^\mu D_\mu(\Gamma\Psi) = -\Gamma\gamma^\mu D_\mu\Psi = -V\,(\Gamma\Psi)$. With $S(\Gamma\Psi) = S(\Psi)$ and $V = m + \lambda S$, the field $\Gamma\Psi$ solves the field equation with $(m, \lambda) \to (-m, -\lambda)$. This is the pairing theorem T1 of the Revision record, which Chapter 18 proves for the Lagrangian; the same calculation holds for complex fields, where Γ also reverses every current.

By Theorem CC, every matrix M that obeys the intertwiner condition $M(\gamma^a)^* = s\,\gamma^a M$ of Section 5.28 (one sign s for all a) is a multiple of 1 or of Γ. On a real field $\Psi^* = \Psi$, so $M\Psi^* = M\Psi$: a multiple of 1 only rescales the field, and among the matrices that obey the condition the only nontrivial one is Γ (up to a factor), which reverses the mass. (Matrices outside the condition are not charge-conjugation matrices; for $V = 0$ some of them, such as P_-, also map solutions to solutions, Section 5.28.) The Revision record states this as: for real fields the matter–antimatter map is the matrix Γ together with $m \to -m$ (check `real_fields_charge_conjugation`). A real commuting field has no charge to reverse (F1); what the map exchanges is the sign of the mass.

statement	**status**	**where it is verified**
the bilinear rule $K' = \epsilon(M^\dagger K M)^T$ and the sign table of S and J	PROVED; COMPUTED exactly	`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, check `bilinears_under_charge_conjugation` (its measured table); Notebook 05c, In [14]
on the free solution: $S = -2$ for all three fields, $J^{(x4)} = -6, +6, -6$	COMPUTED (exact at $x4 = 0$; constant to 10^{-12})	Notebook 05c, In [12] (its own computation)
both reality conditions are consistent ($MM^* = 1$)	PROVED	the same report, check `majorana_conditions_consistent`; Notebook 05c, In [16]
the real condition is kept in time; $\Psi = \Gamma\Psi^*$ is violated by twice the size of $\sin(m\,x4)$	PROVED; COMPUTED for $m = 1,\ 0.5,\ 0$	Notebook 05c, In [17] (its own computation)
real fields: (F1), (F2), (F3)	PROVED	the same report, check `real_fields_charge_conjugation`; Notebook 05c, In [18]

statement	status	where it is verified
normal ordering adds no sign: the quantised field has the signs of the anticommuting rows	PROVED (Section 5.34); COMPUTED on the Fock space; the record states the same (its detail text was corrected on 2026-10-08; the earlier remark that normal ordering adds a sign is withdrawn, so the contradiction is resolved)	Notebook 05e, In [16] to In [18]; the record's detail text of check `bilinears_under_charge_conjugation`

5.30 Example: Notebook 05c computes the charge-conjugation matrices

Notebook 05c turns Sections 5.28 and 5.29 into exact computations on the author's gammas. It reads the gammas from `Revision/algebra/gammas.json` and the lead report `Revision/lead_checks/reports/charge-conjugation-and-u1.json`; it writes the conditions $M(\gamma^a)^* = \pm\gamma^a M$ as two systems of 2048 linear equations for the 256 entries of M and solves them exactly, confirming the result with the zero eigenvalues of $A^T A$; it builds $\mathcal{C}_+$ and $\mathcal{C}_-$ and checks their transposition rules, and solves the transposition equations directly; it applies both maps to a complex column and to the free solution along $x4$, exactly with sympy and on 801 time points; it computes S and $J^{(x4)}$ of the three fields and the full sign table for commuting and anticommuting components; it checks the reality conditions and follows them in time; it treats real fields; and it checks which conjugation keeps the anticommutator of the quantised field. Ten of its checks reproduce checks of the lead report. It draws nine figures and ends with the line ALL 20 CHECKS PASSED (notebook 05c).

5.31 How to run Notebook 05c

Step 1. What this notebook does and what it needs.

Notebook 05c (The charge-conjugation matrices calC_+ = C and calC_- = Gamma C) is the file `Revision/textbook/notebooks/05c_charge_conjugation.ipynb` of the repository Dirac_claude. It derives charge conjugation as a MATRIX map: it solves exactly the linear equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (s = +1: same mass, s = -1: mass reversed; conj is the complex conjugate), finds the two one-dimensional solution spaces spanned by 1 and by Gamma, builds the charge-conjugation matrices calC_+ = C and calC_- = Gamma C, checks their transposition rules, applies them to explicit solutions of the free field equation along the time x4, computes how the bilinears S and J change for commuting and anticommuting components, shows that for REAL fields calC_+ acts as the identity while the real matrix Gamma reverses the mass, and checks which map preserves the canonical anticommutator of the quantised field. Nine teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private

Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05c_charge_conjugation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05c_charge_conjugation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05c_charge_conjugation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- Revision/textbook/figures/05c.captions.json
- Revision/textbook/figures/05c_1_solution_spaces.png
- Revision/textbook/figures/05c_2_conjugation_matrices.png
- Revision/textbook/figures/05c_3_conjugate_solutions.png
- Revision/textbook/figures/05c_4_which_mass.png
- Revision/textbook/figures/05c_5_bilinears.png
- Revision/textbook/figures/05c_6_sign_table.png
- Revision/textbook/figures/05c_7_reality_in_time.png
- Revision/textbook/figures/05c_8_real_field.png
- Revision/textbook/figures/05c_9_quantum_b.png

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the nine figure files of notebook 05c exist
ALL 20 CHECKS PASSED (notebook 05c)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file Revision/textbook/notebooks/05c_charge_conjugation.ipynb inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05c_charge_conjugation.ipynb
python -m nbconvert --execute --inplace 05c_charge_conjugation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra` or in the folder `Revision/lead_checks`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

5.32 Notebook 05c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05c_charge_conjugation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes
```

```
**Charge conjugation is a matrix.** The author's gamma matrices are *real*. For a
*real* field ($\Psi^* = \Psi$) plain complex conjugation changes nothing: it is
the identity, and it cannot exchange matter and antimatter. Charge conjugation must
therefore be defined by a **matrix** $\mathcal{C}$:

$$\Psi^c = \mathcal{C}\, \bar\Psi^T = \mathcal{C} C \Psi^* ,$$

where $\bar\Psi = \Psi^\dagger C$ is the Dirac adjoint and $C$ the charge matrix
(the author's sigma16). As in the Revision record, a charge-conjugation matrix is
defined by a condition that $M = \mathcal{C}C$ must obey together with every gamma
(section 4 derives it); this notebook finds every such matrix exactly. It

1. solves the linear equations $M(\gamma^a)^* = s\,\gamma^a M$ ($a = x0, \dots,
   x7$) for all $16 \times 16$ matrices $M = \mathcal{C}C$: for $s = +1$ (same
   mass) the solutions are the multiples of $1$, for $s = -1$ (mass reversed) the
   multiples of $\Gamma$;
2. builds the two charge-conjugation matrices $\mathcal{C}_+ = C$ and
   $\mathcal{C}_- = \Gamma C$ and checks $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ =
   -(\gamma^a)^T$ and $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$;
3. applies them to explicit solutions of the free field equation along the time
   $x4$ and shows which mass each image solves with;
4. computes how the scalar $S = \bar\Psi\Psi$ and the current $J^a = -i\bar\Psi
   \gamma^a\Psi$ change, for commuting and for anticommuting components;
5. treats **real fields**: $J = 0$, $\mathcal{C}_+$ acts as the identity, and of
   the two matrices the one that changes a real field is $\mathcal{C}_- = \Gamma
   C$, whose map $\Psi \to \Gamma\Psi$ reverses the mass;
6. checks which map preserves the anticommutator $\{\Psi, \Psi^\dagger\} =
   B\,\delta$ of the quantised field: $\Psi \to \Gamma\Psi^{\dagger T}$ does,
   $\Psi \to \Psi^{\dagger T}$ does not.

Ten checks reproduce checks of the Revision record
`Revision/lead_checks/reports/charge-conjugation-and-u1.json`. Nine teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 05c (The charge-conjugation matrices calC_+ = C and calC_- = Gamma C) is the
file `Revision/textbook/notebooks/05c_charge_conjugation.ipynb` of the repository
Dirac_claude. It derives charge conjugation as a MATRIX map: it solves exactly the linear
equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (s = +1: same mass, s
= -1: mass reversed; conj is the complex conjugate), finds the two one-dimensional
solution spaces spanned by 1 and by Gamma, builds the charge-conjugation matrices calC_+
= C and calC_- = Gamma C, checks their transposition rules, applies them to explicit
solutions of the free field equation along the time x4, computes how the bilinears S and
J change for commuting and anticommuting components, shows that for REAL fields calC_+
acts as the identity while the real matrix Gamma reverses the mass, and checks which map
preserves the canonical anticommutator of the quantised field. Nine teaching plots. It
needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
```

mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05c_charge_conjugation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05c_charge_conjugation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05c_charge_conjugation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05c.captions.json‘
- ‘Revision/textbook/figures/05c_1_solution_spaces.png‘
- ‘Revision/textbook/figures/05c_2_conjugation_matrices.png‘
- ‘Revision/textbook/figures/05c_3_conjugate_solutions.png‘
- ‘Revision/textbook/figures/05c_4_which_mass.png‘
- ‘Revision/textbook/figures/05c_5_bilinears.png‘
- ‘Revision/textbook/figures/05c_6_sign_table.png‘
- ‘Revision/textbook/figures/05c_7_reality_in_time.png‘
- ‘Revision/textbook/figures/05c_8_real_field.png‘
- ‘Revision/textbook/figures/05c_9_quantum_b.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the nine figure files of notebook 05c exist
ALL 20 CHECKS PASSED (notebook 05c)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/05c_charge_conjugation.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 05c_charge_conjugation.ipynb
      python -m nbconvert --execute --inplace 05c_charge_conjugation.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘ or in the folder ‘Revision/lead_checks‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 05c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05c (The charge-conjugation matrices calC_+ = C and calC_- = Gamma C) is the
# file Revision/textbook/notebooks/05c_charge_conjugation.ipynb of the repository
# Dirac_claude. It derives charge conjugation as a MATRIX map: it solves exactly the
# linear equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (s = +1:
# same mass, s = -1: mass reversed; conj is the complex conjugate), finds the two
# one-dimensional solution spaces spanned by 1 and by Gamma, builds the
# charge-conjugation matrices calC_+ = C and calC_- = Gamma C, checks their transposition
# rules, applies them to explicit solutions of the free field equation along the time x4,
# computes how the bilinears S and J change for commuting and anticommuting components,
# shows that for REAL fields calC_+ acts as the identity while the real matrix Gamma
# reverses the mass, and checks which map preserves the canonical anticommutator of the
# quantised field. Nine teaching plots. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
```

```
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
```

```
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
```

```
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05c_charge_conjugation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05c_charge_conjugation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 05c_charge_conjugation.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/05c.captions.json
# - Revision/textbook/figures/05c_1_solution_spaces.png
# - Revision/textbook/figures/05c_2_conjugation_matrices.png
# - Revision/textbook/figures/05c_3_conjugate_solutions.png
# - Revision/textbook/figures/05c_4_which_mass.png
# - Revision/textbook/figures/05c_5_bilinears.png
# - Revision/textbook/figures/05c_6_sign_table.png
# - Revision/textbook/figures/05c_7_reality_in_time.png
# - Revision/textbook/figures/05c_8_real_field.png
# - Revision/textbook/figures/05c_9_quantum_b.png
#
# It changes no other file of the repository; running it headless or saving it in
```

```
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the nine figure files of notebook 05c exist
#     ALL 20 CHECKS PASSED (notebook 05c)
#
# and the notebook must show 9 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05c_charge_conjugation.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05c_charge_conjugation.ipynb
#     python -m nbconvert --execute --inplace 05c_charge_conjugation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
```

```
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra or in the folder
#   Revision/lead_checks: the notebook was opened outside the repository, or the
#   repository is incomplete; clone the repository again and open the notebook from its
#   folder Revision/textbook/notebooks.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================
import json  # reads and writes JSON files (text files that hold names and numbers)

## 3. The words used in this notebook

- **Spinor field** $\Psi$: at every point of spacetime a column of 16 numbers
  $\Psi_1, \dots, \Psi_{16}$ (its *components*).
- **Complex conjugate** $z^*$ of $z = a + ib$ is $a - ib$; for a column or matrix,
  every entry is conjugated. A **real** field has $\Psi^* = \Psi$.
- **Transpose** $^T$, **conjugate transpose** $^\dagger$: $M^\dagger = (M^*)^T$; for
  a column $\Psi$, $\Psi^\dagger$ is the row of the conjugated components.
- **Dirac adjoint** $\bar\Psi = \Psi^\dagger C$: a row of 16 numbers.
- **Field equation** (the Euler-Lagrange equation of the Revision record):
  $(\gamma^\mu D_\mu - V)\Psi = 0$ with $V = m + U'(S)$ a real function, $m$ the
  mass, $D_\mu = \partial_\mu + \Omega_\mu$ the covariant derivative with the
  spin connection $\Omega_\mu$.
- **Intertwiner condition** $M(\gamma^a)^* = s\,\gamma^a M$ for $a = x0, \dots,
  x7$, with one sign $s$ ($+1$ or $-1$) for all eight directions: the linear
  equations for $M = \mathcal{C}C$ derived in section 4.
- **Charge-conjugation matrix** $\mathcal{C}$: a constant matrix for which
  $M = \mathcal{C}C$ obeys the intertwiner condition (the definition of the
  Revision record); **same mass** for $s = +1$, **mass reversed** for $s = -1$.
  Section 4 shows that then $\Psi^c = \mathcal{C}\bar\Psi^T$ solves the field
  equation with $V$ (same mass) or with $-V$ (mass reversed) whenever $\Psi$
  solves it.
- **Bilinear**: an expression $\Psi^\dagger K \Psi = \sum_{r,c}\Psi_r^* K_{rc}
  \Psi_c$ with a fixed matrix $K$. The **scalar** $S = \bar\Psi\Psi = \Psi^\dagger C
  \Psi$ and the **current** $J^a = -i\bar\Psi\gamma^a\Psi = \Psi^\dagger(-iC
  \gamma^a)\Psi$; its time component $J^{(x4)} = \Psi^\dagger B\Psi$ (with $B =
  -iC\gamma^{(x4)}$) is the **charge density**.
```

- **Commuting, anticommuting components**: the components of dirac16complex00 are ordinary numbers ($\Psi_r\Psi_c = \Psi_c\Psi_r$); those of dirac16complex are *anticommuting* (Grassmann) numbers, $\Psi_r\Psi_c = -\Psi_c\Psi_r$, so that exchanging two factors in a product costs a sign. We write $\epsilon = +1$ for commuting and $\epsilon = -1$ for anticommuting components.
- **Majorana (reality) condition**: the requirement $\Psi^c = \Psi$.
- **Quantised field, anticommutator**: after quantisation the components are operators with $\{\Psi_r, \Psi_c^\dagger\} = B_{rc}\,\delta$ (δ the delta function of the positions); a conjugation of the quantised field must preserve this rule.

Text cell:

```
## 4. The physical and mathematical situation

**Deriving the condition on the matrix.** Let $\Psi$ solve
$\gamma^\mu D_\mu\Psi = V\Psi$ with real $V$. In the Revision record the gammas
$\gamma^\mu = e^\mu{}_a\gamma^a$ and the spin connection $\Omega_\mu$ are real (the
lead check spinor_connection_real), so the operator $\gamma^\mu D_\mu$ is real.

1. Take the complex conjugate of the equation. Every real factor stays, so
   $\gamma^\mu D_\mu\Psi^* = V\Psi^*$: $\Psi^*$ solves the same equation.
2. Multiply from the left by a constant matrix $M$:
   $M\gamma^\mu D_\mu\Psi^* = V M\Psi^*$.
3. Suppose $M\gamma^a = s\,\gamma^a M$ for every $a$, with one sign $s = \pm1$.
   The spin connection is built from the $S^{ab} = \tfrac12\gamma^a\gamma^b$, and
   $M\gamma^a\gamma^b = s^2\gamma^a\gamma^b M = \gamma^a\gamma^b M$, so $M$
   commutes with $\Omega_\mu$ and $MD_\mu = D_\mu M$.
4. Hence $M\gamma^\mu D_\mu\Psi^* = s\,\gamma^\mu D_\mu(M\Psi^*)$, and step 2 becomes
   $s\,\gamma^\mu D_\mu(M\Psi^*) = V(M\Psi^*)$. Multiply by $s$ ($s^2 = 1$):
   $$\gamma^\mu D_\mu(M\Psi^*) = sV\,(M\Psi^*) .$$
   The new field $M\Psi^*$ solves the equation with $V$ when $s = +1$ and with $-V$
   when $s = -1$.
5. $V = m + U'(S)$ depends on the field through $S$. For commuting components and
   the two matrices found below, the new field has the same $S$ as $\Psi$ (section
   10 computes this). With $U = \tfrac\lambda2 S^2$, $V = m + \lambda S$, so the new
   field solves the field equation with the parameters $(m, \lambda)$ when $s = +1$
   and $(-m, -\lambda)$ when $s = -1$.

Because the gammas are real, $(\gamma^a)^* = \gamma^a$, and the condition reads
$M(\gamma^a)^* = s\,\gamma^a M$: $M$ commutes ($s = +1$) or anticommutes
($s = -1$) with every gamma. The textbook form is $\Psi^c = \mathcal{C}\bar\Psi^T$:
since $\bar\Psi^T = (\Psi^\dagger C)^T = C^T\Psi^* = C\Psi^*$, we have
$\Psi^c = \mathcal{C}C\Psi^*$, so $M = \mathcal{C}C$ and $\mathcal{C} = MC^{-1} =
MC$ (because $CC = 1$).

**What the equations can give.** The matrices commuting with all gammas are the
multiples of 1 (Pin(4,4) is irreducible). If $M$ anticommutes with all gammas,
then $\Gamma M$ commutes with all of them ($\Gamma$ anticommutes with every gamma),
so $\Gamma M = c\,1$ and $M = c\,\Gamma$. The notebook solves the equations exactly
and finds exactly these two one-dimensional families.

**Why the condition is the definition.** Steps 1 to 4 show that the condition is
```

```
enough for $M\Psi^*$ to be a solution; the converse is not true in general. For
$V = 0$ (mass 0, no self-interaction) the chiral projector $P_- = \frac12(1 -
\Gamma)$ is even, so it commutes with $\Omega_\mu$ and $\partial_\mu$, and
$\gamma^a P_- = P_+\gamma^a$ with $P_+ = \frac12(1 + \Gamma)$; hence
$\gamma^\mu D_\mu(P_-\Psi^*) = P_+\gamma^\mu D_\mu\Psi^* = P_+ V\Psi^* = 0$ for
every solution. So $P_-$ maps every solution to a solution, but it is neither a
multiple of 1 nor of $\Gamma$ and obeys neither condition. With the condition as
the definition (as in the Revision record) there are exactly two
charge-conjugation matrices, up to a factor.

**A field along the time.** In flat space, a field that depends only on $x4$
obeys $\gamma^{(x4)}\, d\Psi/dx4 = m\Psi$. Since $\gamma^{(x4)}\gamma^{(x4)} = -1$,
multiplying by $-\gamma^{(x4)}$ gives $d\Psi/dx4 = -m\gamma^{(x4)}\Psi$, solved by

$$\Psi(x4) = \cos(m\,x4)\,\Psi_0 - \sin(m\,x4)\,\gamma^{(x4)}\Psi_0$$

for any constant column $\Psi_0$: the derivative is $d\Psi/dx4 = -m\sin(m\,x4)
\Psi_0 - m\cos(m\,x4)\gamma^{(x4)}\Psi_0$ (the chain rule: $d\cos(m\,x4)/dx4 =
-m\sin(m\,x4)$ and $d\sin(m\,x4)/dx4 = m\cos(m\,x4)$), and $\gamma^{(x4)}$ times it
is $-m\sin(m\,x4)\gamma^{(x4)}\Psi_0 - m\cos(m\,x4)\gamma^{(x4)}\gamma^{(x4)}\Psi_0
= -m\sin(m\,x4)\gamma^{(x4)}\Psi_0 + m\cos(m\,x4)\Psi_0 = m\Psi$ (using
$\gamma^{(x4)}\gamma^{(x4)} = -1$). The notebook uses this solution to show the two
conjugations at work.
```

Text cell:

```
## 5. The gammas, C, Gamma, B and the recorded checks

The next cell reads the gammas (exact whole numbers) from
‘Revision/algebra/gammas.json‘, builds $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}
\gamma^{(x3)}$, $\Gamma = \gamma^{(x0)}\gamma^{(x1)}\cdots\gamma^{(x7)}$ and $B =
-iC\gamma^{(x4)}$, and reads the lead report. The helpers: ‘recorded(name)‘ is true
when the report holds the check ‘name‘ with the verdict pass, ‘detail(name)‘ is its
detail text, ‘RECORD‘ the report file, and ‘check_reproduces(condition, name,
record)‘ is the helper ‘check‘ for a check that reproduces a Revision record: it
lets ‘check‘ print the PASS line and the line "reproduces ..." into a text buffer
(‘contextlib.redirect_stdout‘) and sends both lines with one ‘sys.stdout.write‘,
because Jupyter delivers printed text in pieces and one piece keeps the two lines
together for the tools that read the notebook. The first two checks repeat the
recorded reality facts.
```

## 6. Solving for every conjugation matrix M

The next cell turns $M(\gamma^a)^* - s\,\gamma^a M = 0$ ($a = x0, \dots, x7$) into
$8 \times 256 = 2048$ linear equations for the 256 entries of $M$, read row by row.
The entry $(r, c)$ of $M G$ is $\sum_k M_{rk}G_{kc}$ (the unknown $M_{rk}$ has the
coefficient $G_{kc}$) and of $G M$ it is $\sum_k G_{rk}M_{kc}$ (the unknown $M_{kc}$
has the coefficient $G_{rk}$); collected, the coefficient matrix of $MG - sGM$ is
$\mathrm{kron}(1, G^T) - s\,\mathrm{kron}(G, 1)$. sympy's `DomainMatrix` over the
rational numbers `QQ` computes the solutions exactly (its `nullspace`). The
conjugate `np.conj(gamma[x])` is written out although it equals `gamma[x]`: the
gammas are real.
```

## 7. The two charge-conjugation matrices

From $\mathcal{C} = MC$ (section 4): $M = 1$ gives $\mathcal{C}_+ = C$ and
$M = \Gamma$ gives $\mathcal{C}_- = \Gamma C$. Their transposition rules:

- $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = C\gamma^a C = -(\gamma^a)^T$ (the
  rule $C\gamma^aC^{-1} = -(\gamma^a)^T$ of the charge matrix);
- $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = C\Gamma\gamma^a\Gamma C =
  C(-\gamma^a)C = +(\gamma^a)^T$ (first $\Gamma\gamma^a\Gamma = -\gamma^a\Gamma
  \Gamma = -\gamma^a$, then the rule of $C$).

The next cell checks both rules, that both matrices are real, that
$\mathcal{C}_+$ is symmetric, and also that $\mathcal{C}_-$ is symmetric with
$\mathcal{C}_-\mathcal{C}_- = 1$. Then it solves, as an independent derivation, the
transposition equations $\gamma^a X = \zeta\, X(\gamma^a)^T$ for all $a$
directly: for $\zeta = -1$ the only solutions must be the multiples of $C$, for
$\zeta = +1$ those of $\Gamma C$.
```

## 9. The conjugate fields solve the equation with the mass predicted

The next cell builds, with sympy and **exactly**, the solution $\Psi(x4) =
\cos(m\,x4)\Psi_0 - \sin(m\,x4)\gamma^{(x4)}\Psi_0$ for a general real mass $m$, and
its two images $\Psi^c_+ = \Psi^*$ and $\Psi^c_- = \Gamma\Psi^*$. For each of the
three fields and each mass $+m$ and $-m$ it computes the residual
$\gamma^{(x4)} d\Phi/dx4 - (\pm m)\Phi$ (which is zero exactly when $\Phi$ solves the
equation with that mass) and expands it. Prediction: $\Psi$ and $\Psi^*$ solve
with $+m$, $\Gamma\Psi^*$ with $-m$, and no field solves with both (for
$m \neq 0$).
```

In [8]:

```
x4, m = sp.symbols("x4 m", real=True)  # the time and the mass, real numbers
psi0 = sp.Matrix([sp.Integer(int(z.real)) + sp.I * sp.Integer(int(z.imag))
                  for z in PSI0])
G4 = sp.Matrix(gamma["x4"].tolist())  # gamma^(x4) as an exact sympy matrix

## 10. The scalar S and the charge density J for commuting components

For commuting components (the field dirac16complex00) the next cell computes,
along the solution, the scalar $S = \Psi^\dagger C\Psi$ and the charge density
$J^{(x4)} = \Psi^\dagger B\Psi$ of the three fields at all 801 time points. Both
are constant along $x4$ (the derivative of $S$ is $-m\Psi^\dagger(
(\gamma^{(x4)})^TC + C\gamma^{(x4)})\Psi = 0$, because $(\gamma^{(x4)})^T =
-\gamma^{(x4)}$ commutes with $C$; the same computation with $B$ in place of $C$
gives 0 for $J^{(x4)}$, because $\gamma^{(x4)}$ also commutes with $B$). The
prediction of the Revision record for commuting components: $\Psi^*$ keeps $S$ and
reverses $J$; $\Gamma\Psi^*$ keeps $S$ and keeps $J$. The cell also checks the
exact values $S = -2$ and $J^{(x4)} = -6$ of the solution at $x4 = 0$ (where
$\Psi = \Psi_0$), which the next figure shows.
```

## 11. The sign table for commuting and anticommuting components

For a bilinear $\Psi^\dagger K\Psi = \sum_{r,c}\Psi_r^* K_{rc}\Psi_c$ and the map
$\Psi \to M\Psi^*$ with a real $M$, line by line:

1. $(M\Psi^*)^\dagger = \Psi^T M^\dagger$ (the conjugate of $\Psi^*$ is $\Psi$), so
   the bilinear becomes $\Psi^T M^\dagger K M\Psi^* = \sum_{r,c}\Psi_r\,
   (M^\dagger KM)_{rc}\,\Psi_c^*$.
2. Exchange the two factors $\Psi_r$ and $\Psi_c^*$; this costs the sign
   $\epsilon$: $\sum_{r,c}\epsilon\,\Psi_c^*(M^\dagger KM)_{rc}\Psi_r$.
3. Rename $r \leftrightarrow c$: this is $\Psi^\dagger K'\Psi$ with
   $K' = \epsilon\,(M^\dagger KM)^T$.

So the bilinear with matrix $K$ turns into the bilinear with matrix $K'$. The next
cell computes $K'$ for $K = C$ (the scalar $S$) and $K = -iC\gamma^a$ (the eight
currents $J^a$), for $M = 1$ ($\mathcal{C}_+$) and $M = \Gamma$ ($\mathcal{C}_-$)
and $\epsilon = \pm1$, and records the sign with $K' = \pm K$. It compares the
table with the signs that the Revision record measured (stored in its detail text
after the word measured).

For the *quantised* field dirac16complex the components are operators. Exchanging
two of them costs the same sign as for anticommuting numbers and leaves a constant
behind (their anticommutator); normal ordering removes that constant and nothing
else. So after normal ordering the quantised bilinears change with the signs of the
anticommuting rows of this table. Notebook 05e computes this on an explicit Fock
space. The detail text of the record's check says the same: normal ordering adds
no sign, because it subtracts the vacuum value, which is a number.

## 12. The reality (Majorana) conditions

A field equal to its own conjugate obeys $\Psi = M\Psi^*$. Taking the complex
conjugate of this condition gives $\Psi^* = M^*\Psi$, and putting it back gives
$\Psi = MM^*\Psi$. So the condition agrees with itself for every column that obeys
it (it is *consistent*) when $MM^* = 1$; otherwise it would force further
conditions, possibly $\Psi = 0$. The next cell checks $MM^* = 1$ for $M = 1$ (the
condition $\Psi = \Psi^*$: a real field) and for $M = \Gamma$ (the condition
$\Psi = \Gamma\Psi^*$: the first half imaginary, the second half real).
```

In [16]:

```
check_reproduces(np.array_equal(I16 @ np.conj(I16), I16)
                 and np.array_equal(Gamma @ np.conj(Gamma), I16)
                 and recorded("majorana_conditions_consistent"),
                 "M M* = 1 for M = 1 and M = Gamma: both reality conditions are "
                 "consistent",
                 record=f"{RECORD}, check majorana_conditions_consistent")
```

Out [16]:

```
PASS M M* = 1 for M = 1 and M = Gamma: both reality conditions are consistent
     reproduces Revision/lead_checks/reports/charge-conjugation-and-u1.json, check
    majorana_conditions_consistent
```

Text cell:

```
Consistency is a statement about one moment. Is the condition kept as the field
evolves? For the solution $\Psi(x4)$ of section 9 with a starting column that obeys
the condition:

- start real ($\Psi_0^* = \Psi_0$): all factors of the solution are real, so
  $\Psi(x4)$ stays real at all times;
- start with $\Psi_0 = \Gamma\Psi_0^*$: then $\Gamma\Psi(x4)^* = \cos(m x4)\Gamma
  \Psi_0^* - \sin(m x4)\Gamma\gamma^{(x4)}\Psi_0^* = \cos(m x4)\Psi_0 + \sin(m x4)
  \gamma^{(x4)}\Psi_0$ (because $\Gamma\gamma^{(x4)} = -\gamma^{(x4)}\Gamma$), so
  $\Psi(x4) - \Gamma\Psi(x4)^* = -2\sin(m x4)\gamma^{(x4)}\Psi_0$, whose size is
  $2|\sin(m x4)|\,|\Psi_0|$ ($\gamma^{(x4)}$ is a signed permutation and keeps
  sizes).

So the second condition holds at all times only for $m = 0$. This is what
"mass reversed" means: a field equal to its $\mathcal{C}_-$ image would have to
solve the equation with $V$ and with $-V$ at once. The next cell computes both
violations for $m = 1$, $m = 0.5$ and $m = 0$ and draws them.
```

## 13. Real fields

For a **real** commuting field ($\Psi^* = \Psi$):

- the currents vanish identically: $J^a = -i\Psi^TC\gamma^a\Psi = 0$, because
  $C\gamma^a$ is antisymmetric and $u^TAu = 0$ for every antisymmetric $A$ (the
```

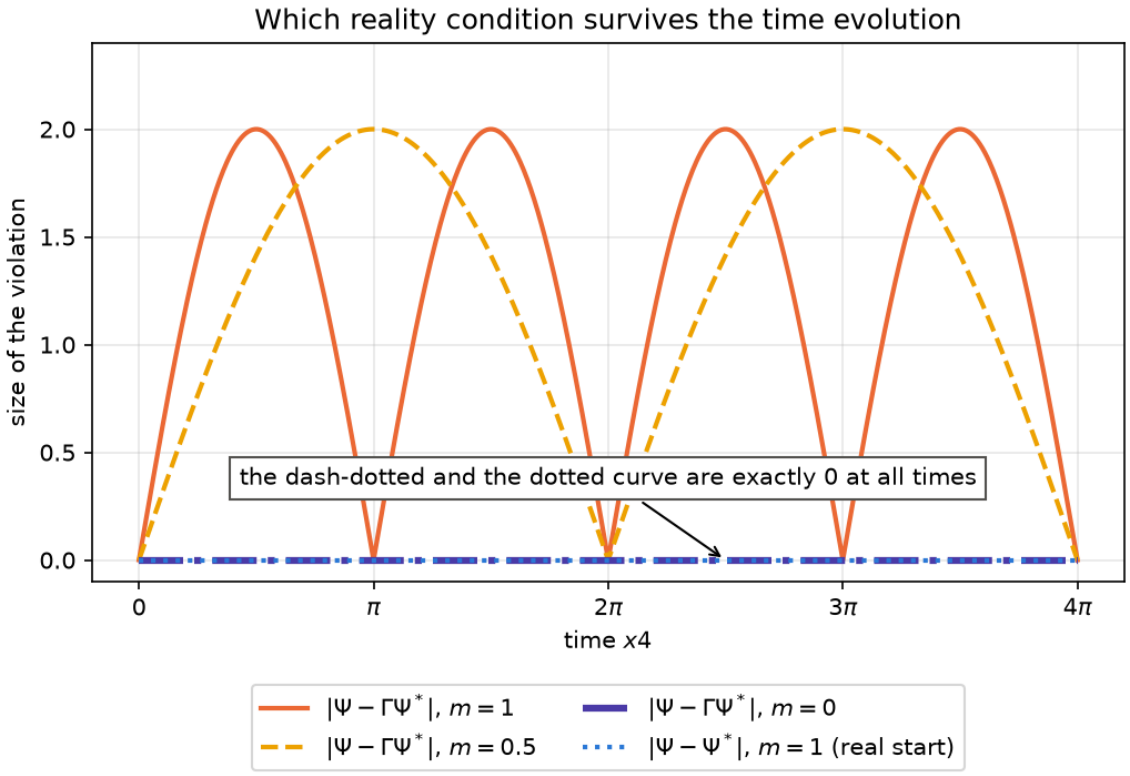

Figure 171: How far the free solution moves away from the two reality conditions, for starting columns of size 1 that obey them: the size of $\Psi - \Gamma\Psi^*$ for the masses $m = 1$ (solid), $m = 0.5$ (dashed) and $m = 0$ (dash-dotted, zero), and the size of $\Psi - \Psi^*$ for a real start (dotted, zero); horizontal axis the time $x4$, vertical axis the size (a pure number). The real field stays real; the condition $\Psi = \Gamma\Psi^*$ of the mass-reversing conjugation is violated by $2|\sin(mx4)|$ unless $m = 0$. (Notebook 05c, figure 7.)

```
  terms $u_rA_{rc}u_c$ and $u_cA_{cr}u_r$ cancel); a real field carries no U(1)
  charge;
- $\mathcal{C}_+$ acts as the identity: $\Psi^c_+ = \Psi^* = \Psi$ (a real field is
  its own conjugate);
- the **real matrix** $\Gamma$ maps real fields to real fields, keeps $S$
  ($\Gamma^TC\Gamma = C$) and reverses every kinetic matrix ($\Gamma^TC\gamma^a\Gamma
  = -C\gamma^a$): with $(m, \lambda) \to (-m, -\lambda)$ it maps solutions to
  solutions (the pairing theorem T1 of the Revision record).

The next cell checks the first statement with sympy for 16 real symbols $r_1, \dots,
r_{16}$ (all real columns at once), and the third one with exact matrices and on
the real solution $\Psi(x4)$ that starts at the real part of $\Psi_0$: $\Gamma\Psi$
solves the equation with $-m$.

## 14. The quantised field

After quantisation, the components of dirac16complex are operators with
$\{\Psi_r, \Psi_c^\dagger\} = B_{rc}\,\delta$. Consider the map $\Psi \to
M\Psi^{\dagger T}$ (the operator form of $M\Psi^*$) with a real $M$. Its adjoint
is $\Psi^\dagger \to (M\Psi^{\dagger T})^\dagger = \Psi^TM^\dagger$. The
anticommutator of the new operators is then $M\{\Psi^{\dagger T}, \Psi^T\}
M^\dagger = M B^T M^\dagger\,\delta$ (the anticommutator of $\Psi_c^\dagger$ with
$\Psi_r$ is $B_{rc}$, which is the entry $(c, r)$ of $B^T$). The rule is preserved
exactly when $MB^TM^\dagger = B$. The next cell checks the recorded result: it holds
for $M = \Gamma$ and fails for $M = 1$, where it gives $-B$ (because $B^T = -B$).
A factor $\lambda$ in front of $M$ multiplies $MB^TM^\dagger$ by $|\lambda|^2$, so
among the multiples of 1 and of $\Gamma$ only $\Gamma$, up to a phase factor
$e^{i\alpha}$, keeps the rule.
```

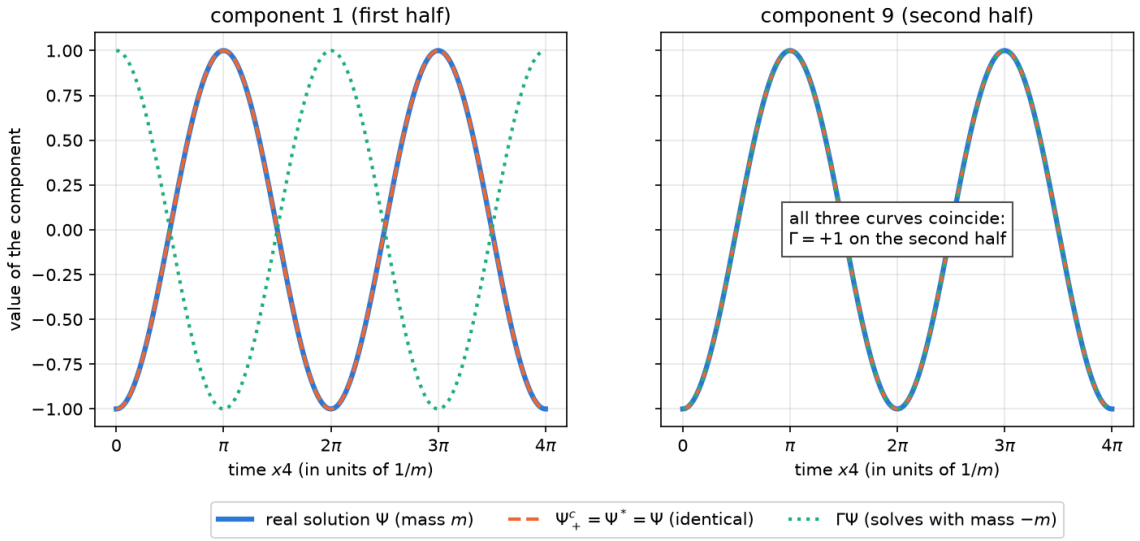

Figure 172: A real solution of the free equation (solid), its same-mass conjugate $\Psi^* = \mathcal{C}_+\bar{\Psi}^T$ (dashed, lying exactly on the solid line) and its image $\Gamma\Psi$ under the real chirality matrix (dotted), for component 1 (left, first half) and component 9 (right, second half); horizontal axis the time $x4$ in units of $1/m$, vertical axis the value. For a real field the same-mass conjugation does nothing; of the two charge-conjugation matrices only ΓC changes a real field: its map $\Psi \to \Gamma\Psi$ flips the first half and solves the equation with the mass reversed. (Notebook 05c, figure 8.)

## 16. What this notebook showed

- Because the author's gammas are real, plain complex conjugation does nothing to a
  real field; charge conjugation is a **matrix** map $\Psi^c = \mathcal{C}\bar\Psi^T
  = \mathcal{C}C\Psi^*$.
- Solving $M(\gamma^a)^* = s\,\gamma^a M$ exactly: for $s = +1$ (same mass) only
  the multiples of 1, for $s = -1$ (mass reversed) only the multiples of $\Gamma$.
  Hence, with this intertwiner condition as the definition (as in the Revision
  record), exactly two charge-conjugation matrices up to a factor; each maps every
  solution to a solution (the converse is not claimed: for $V = 0$ the projector
  $P_-$ also does). They are $\mathcal{C}_+ = C$ with
  $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$, $\Psi^c = \Psi^*$; and
  $\mathcal{C}_- = \Gamma C$ with $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- =
  +(\gamma^a)^T$, $\Psi^c = \Gamma\Psi^*$. Solving the transposition equations
  directly gives the same two matrices.
- On explicit solutions: $\Psi^*$ solves the equation with the same mass,
  $\Gamma\Psi^*$ with the mass reversed (exact sympy computation and numbers).
- Commuting components: $\mathcal{C}_+$ keeps $S$ and reverses $J$;
  $\mathcal{C}_-$ keeps both. Anticommuting components: one more sign on each
  (classically), as the Revision record measured. For the quantised field the
  normal-ordered bilinears have the signs of the anticommuting components
  (computed in Notebook 05e).
- Both reality conditions are consistent ($MM^* = 1$); the real one is kept in
  time, the $\Gamma$ one only for $m = 0$.
- Real fields: $J = 0$, $\mathcal{C}_+$ is the identity, and among the matrices
  that obey the intertwiner condition the only nontrivial one is $\Gamma$ (up to a
  factor), with $(m, \lambda) \to (-m, -\lambda)$ (theorem T1).
- Quantised field: $\Psi \to \Gamma\Psi^{\dagger T}$ preserves $\{\Psi,
  \Psi^\dagger\} = B\delta$, $\Psi \to \Psi^{\dagger T}$ does not; among the
  multiples of the two matrices only $\Gamma$, up to a phase factor, keeps the
  rule, and this conjugation of the quantised field reverses the mass.
- Ten checks reproduce the Revision record
  `Revision/lead_checks/reports/charge-conjugation-and-u1.json`.
```

5.33 Line-by-line walk-through of Notebook 05c

The notebook has 21 code cells. In [1] is the set-up cell of Section 5.10 with `NOTEBOOK_ID = "05c"`; its comments repeat the instructions of Section 5.31. As in the earlier walk-throughs, the docstrings of the functions (the texts in triple quotes below a `def` line) are left out of the quotations, and a long caption given to `save_figure` is shortened to `...`; the full caption is printed under the figure in the complete text of the notebook.

In [2], the gammas, C, Γ, B and the lead report.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra
```

The modules `contextlib`, `io` and `sys` serve the helper `check_reproduces` below; numpy is loaded under its short name `np`.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1
```

These lines read the record of the gammas exactly as Notebook 05a does (Section 5.10, In [2]): `fixture` is the record, `COORDS` the eight coordinate names, `ETA` the signs η_{aa}, `gamma` the eight matrices as arrays of whole numbers (so that every product is exact) and `I16` the identity. A statement may run over two lines when the line break stands inside a bracket, as in the first line.

```
def product(directions):
    result = I16
    for d in directions:
        result = result @ gamma[d]
    return result
```

`product(["x0", "x1"])` multiplies the gammas of the listed directions in the order of the list, starting from the identity; `@` is the matrix product.

```
C = product(["x0", "x1", "x2", "x3"])  # the charge matrix (sigma16)
Gamma = product(["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"])  # the chirality
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4)
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]
S_gen = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4 for a, b in pairs}
```

C, Γ and $B = -iC\gamma^{(x4)}$ are built as in Sections 5.4 to 5.6 (`1j` is Python's imaginary unit i). `pairs` lists the 28 planes (a, b) with a before b (`enumerate` gives each name with its position `i`, and `COORDS[i + 1:]` is the list of the names after it), and `S_gen` holds the 28 generators $S^{ab} = \frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$.

```
RECORD = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
lead = json.loads(repository_file(RECORD).read_text(encoding="utf-8"))
LEAD = {c["name"]: (c["verdict"].lower(), c["detail"]) for c in lead["checks"]}
```

`RECORD` is the path of the lead report. `lead` is the whole report read as a dictionary; `lead["checks"]` is its list of checks, and the dictionary comprehension stores each check under its name as the pair (verdict in small letters, detail text).

```
def recorded(name):
    return LEAD[name][0] == "pass"

def detail(name):
    return LEAD[name][1]

def check_reproduces(condition, name, record):
    collected = io.StringIO()
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together
```

`recorded(name)` is true when the lead report holds the check `name` with the verdict pass; `detail(name)` is its detail text (the second element `[1]` of the stored pair). `check_reproduces` is the helper of Notebook 05a (Section 5.10, In [3]): it lets `check` print the PASS line and the line that names the reproduced record into a text buffer and then sends both lines at once.

```
passed, total = lead["summary"]["passed"], lead["summary"]["total"]
say(f"the lead report holds {len(LEAD)} checks; passed: {passed} of {total}")
is_real = all(not np.iscomplexobj(gamma[x]) for x in COORDS)
```

The first line reads the two numbers of the report's summary; the printed line says that the report holds 12 checks, all passed. `np.iscomplexobj` is true for an array of complex numbers; `is_real` is true when none of the eight gammas is complex.

```
check_reproduces(is_real and np.array_equal(C.T, C) and np.array_equal(C @ C, I16)
                 and all(np.isrealobj(s) for s in S_gen.values())
                 and recorded("representation_real"),
                 "the gammas, C (symmetric, C C = 1) and the S^ab are real",
                 record=f"{RECORD}, check representation_real")
check_reproduces(not np.any(B.real) and np.array_equal(B.conj().T, B)
                 and np.array_equal(B @ B, I16) and recorded("B_imaginary_hermitian"),
                 "B = -i C gamma^(x4) is purely imaginary and Hermitian, B B = 1",
                 record=f"{RECORD}, check B_imaginary_hermitian")
```

The first check: the gammas are real, $C^T = C$, $CC = 1$, and every generator is real (`np.isrealobj`); this is the fact that makes plain complex conjugation do nothing on a real field. The second check: the real part of B is zero everywhere (`not np.any(B.real)`), $B^\dagger = B$ (`B.conj().T` is the conjugate transpose) and $BB = 1$. Both print PASS and the lead check they reproduce.

In [3], every conjugation matrix, solved exactly.

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over QQ

def conjugation_system(s):
    blocks = []
```

```
    for x in COORDS:
        G = np.conj(gamma[x]).astype(np.int64)  # (gamma^a)*, equal to gamma^a
        blocks.append(np.kron(I16, G.T) - s * np.kron(gamma[x], I16))
    return np.vstack(blocks)
```

`conjugation_system(s)` builds the coefficient matrix of the 2048 linear equations $M(\gamma^a)^* - s\,\gamma^a M = 0$, $a = x0, \ldots, x7$, for the 256 entries of M listed row by row. The rule of Section 5.13 for $LX - XR$ is used with the roles turned around: the entry (r, c) of MG is $\sum_k M_{rk} G_{kc}$, and the coefficient matrix of $M \to MG$ is $\mathrm{kron}(1, G^T)$; the entry (r, c) of GM is $\sum_k G_{rk} M_{kc}$, with the coefficient matrix $\mathrm{kron}(G, 1)$. `np.conj` writes out the complex conjugate although it equals the gamma (the gammas are real), so that the code says exactly what the equation says; `np.vstack` stacks the eight blocks of 256 rows.

```
def exact_solutions(A, n=16):
    null = DomainMatrix.from_list(A.tolist(), sp.QQ).nullspace().to_Matrix()
    return [np.array(null.row(k).tolist()[0], dtype=float).reshape(n, n)
            for k in range(null.rows)]
```

`exact_solutions(A)` returns a basis of all solutions of $Ay = 0$, each turned back into a 16×16 matrix, as `solution_basis` of Notebook 05b does (Section 5.17, In [3]): sympy's `DomainMatrix` over the rational numbers `QQ` finds the solutions by exact elimination, `nullspace()` returns one solution per row, and `reshape(n, n)` restores the matrix (`n=16` is a **default value**: the argument may be left out).

```
def proportional(X, Y):
    stacked = np.array([X.reshape(-1), Y.reshape(-1)], dtype=float)
    return bool(X.any() and Y.any() and np.linalg.matrix_rank(stacked) == 1)
```

`proportional(X, Y)` is true when both matrices are nonzero and one is a number times the other: written as two rows of 256 numbers (`reshape(-1)` lays out all entries in one row), they must have rank 1. `bool(...)` turns the result into a plain true or false.

```
A_same, A_reversed = conjugation_system(+1), conjugation_system(-1)
M_same, M_reversed = exact_solutions(A_same), exact_solutions(A_reversed)
say(f"s = +1: {A_same.shape[0]} equations, {len(M_same)} independent solution(s)")
say(f"s = -1: {A_reversed.shape[0]} equations, {len(M_reversed)} independent "
    f"solution(s)")
```

The two systems are built and solved. The printed lines report, for each sign, 2048 equations and 1 independent solution.

```
check_reproduces(len(M_same) == 1 and proportional(M_same[0], I16)
                 and "dimension 1" in detail("intertwiners_same_mass")
                 and recorded("intertwiners_same_mass"),
                 "M (gamma^a)* = + gamma^a M: one solution, the identity (same mass)",
                 record=f"{RECORD}, check intertwiners_same_mass")
check_reproduces(len(M_reversed) == 1 and proportional(M_reversed[0], Gamma)
```

```
        and "dimension 1" in detail("intertwiners_reversed_mass")
        and recorded("intertwiners_reversed_mass"),
        "M (gamma^a)* = - gamma^a M: one solution, Gamma (mass reversed)",
        record=f"{RECORD}, check intertwiners_reversed_mass")
```

Theorem CC (a) as two checks: for $s = +1$ exactly one solution, proportional to the identity; for $s = -1$ exactly one, proportional to Γ. Each also requires that the record's detail text contains the words `dimension 1`, the dimension the record found.

In [4], the second engine and the picture of the solutions.

```
from matplotlib.colors import LinearSegmentedColormap

SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])

def heat_map(ax, matrix, title, row_label=True):
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 3, 7, 11, 15], ["1", "4", "8", "12", "16"])
    ax.set_yticks([0, 3, 7, 11, 15], ["1", "4", "8", "12", "16"])
    ax.axhline(7.5, color="black", linewidth=0.8)
    ax.axvline(7.5, color="black", linewidth=0.8)
    ax.set_xlabel("column")
    if row_label:
        ax.set_ylabel("row")
    ax.grid(False)
    return image
```

The colour map (blue -1, light grey 0, red $+1$) and the heat map of Notebook 05a (Section 5.10, In [6]), here always for a 16×16 matrix with the two black lines between the halves.

```
eigen_same = np.linalg.eigvalsh((A_same.T @ A_same).astype(float))
eigen_reversed = np.linalg.eigvalsh((A_reversed.T @ A_reversed).astype(float))
zeros_same = int(np.sum(np.abs(eigen_same) < 1e-9))
zeros_reversed = int(np.sum(np.abs(eigen_reversed) < 1e-9))
say(f"zero eigenvalues of A^T A: s = +1: {zeros_same}; s = -1: {zeros_reversed}")
check(zeros_same == 1 and zeros_reversed == 1,
      "numerical second engine: exactly one zero eigenvalue for each sign")
```

The second engine of Section 5.13: the number of solutions of $Ay = 0$ equals the number of zero eigenvalues of the symmetric matrix $A^T A$. `np.linalg.eigvalsh` computes the 256 eigenvalues in floating-point numbers (sorted from small to large), and the eigenvalues below 10^{-9} in size are counted. The printed line shows one for each sign, and the check requires it.

```
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.0), width_ratios=[1, 1, 1.3])
shown_same = M_same[0] / M_same[0][0, 0]  # scaled: entry (1,1) equal to 1
shown_reversed = M_reversed[0] / M_reversed[0][0, 0] * Gamma[0, 0]  # as in Gamma
heat_map(axes[0], shown_same, "solution for $s = +1$")
image = heat_map(axes[1], shown_reversed, "solution for $s = -1$", row_label=False)
```

A solution is fixed only up to a factor. The solution for $s = +1$ is divided by its entry in row 1, column 1, so that this entry becomes 1, like the identity's; the solution for $s = -1$ is scaled so that this entry equals the one of Γ, which is -1. Both are drawn as heat maps.

```
index = np.arange(1, 257)
axes[2].plot(index, eigen_same, color="#2a78d6", linewidth=2,
             label="$s = +1$ (same mass)")
axes[2].plot(index, eigen_reversed, color="#eb6834", linewidth=2, linestyle="--",
             label="$s = -1$ (mass reversed)")
axes[2].plot([1], [eigen_same[0]], "o", color="#2a78d6", markersize=9)
axes[2].plot([1], [eigen_reversed[0]], "o", color="#eb6834", markersize=9)
axes[2].set_xlabel("number of the eigenvalue (sorted)")
axes[2].set_ylabel("eigenvalue of $A^T A$")
axes[2].set_title("one zero eigenvalue for each sign")
axes[2].legend(loc="lower right")
fig.colorbar(image, ax=axes[:2], ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "solution_spaces",
            ...)
```

The third picture plots the sorted eigenvalues of the two systems against their numbers 1 to 256, and a large dot on the first (smallest) eigenvalue of each, which is the zero one. The colour bar belongs to the first two pictures (`axes[:2]`). **What figure 05c.1 shows**: on the left the identity (a red diagonal), in the middle Γ (blue on the first eight diagonal places, red on the last eight), on the right two staircase curves of eigenvalues that each touch zero exactly once. The student should see that each equation system leaves exactly one free direction: the identity for the same mass, Γ for the reversed mass.

In [5], the two charge-conjugation matrices.

```
calC_plus = (M_same[0] / M_same[0][0, 0]) @ C  # M = 1 (scaled), so calC_+ = C
calC_minus = Gamma @ C  # M = Gamma, so calC_- = Gamma C
inverse_plus = np.linalg.inv(calC_plus)
inverse_minus = np.linalg.inv(calC_minus)
```

From $\mathcal{C} = MC$: the solution for $s = +1$, scaled to the identity, times C gives $\mathcal{C}_+$; ΓC is $\mathcal{C}_-$. `np.linalg.inv` computes the inverse matrices (for these signed permutation matrices the floating-point inverse is exact).

```
check_reproduces(np.array_equal(calC_plus, C)
                 and all(np.array_equal(inverse_plus @ gamma[x] @ calC_plus, -gamma[x].T)
                         for x in COORDS)
                 and np.array_equal(calC_plus.T, calC_plus)
                 and recorded("charge_conjugation_matrix_plus"),
                 "calC_+ = C: calC_+^-1 gamma^a calC_+ = -(gamma^a)^T, real and "
                 "symmetric",
                 record=f"{RECORD}, check charge_conjugation_matrix_plus")
check_reproduces(all(np.array_equal(inverse_minus @ gamma[x] @ calC_minus, gamma[x].T)
                     for x in COORDS)
                 and np.isrealobj(calC_minus)
                 and np.array_equal(calC_minus.T, calC_minus)
```

```
                and np.array_equal(calC_minus @ calC_minus, I16)
                and recorded("charge_conjugation_matrix_minus"),
                "calC_- = Gamma C: calC_-^-1 gamma^a calC_- = +(gamma^a)^T, real",
                record=f"{RECORD}, check charge_conjugation_matrix_minus")
```

Theorem CC (b) and (c): $\mathcal{C}_+ = C$ with $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$ for all eight directions, symmetric; $\mathcal{C}_-$ with $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$, real, symmetric and with square 1.

```
def transposition_system(zeta):
    return np.vstack([np.kron(gamma[x], I16) - zeta * np.kron(I16, gamma[x])
                      for x in COORDS])

X_minus = exact_solutions(transposition_system(-1))  # should be multiples of C
X_plus = exact_solutions(transposition_system(+1))  # should be multiples of Gamma C
say(f"zeta = -1: {len(X_minus)} solution(s); zeta = +1: {len(X_plus)} solution(s)")
check(len(X_minus) == 1 and proportional(X_minus[0], C)
      and len(X_plus) == 1 and proportional(X_plus[0], Gamma @ C),
      "the only solutions of gamma^a X = -X (gamma^a)^T are multiples of C, of "
      "gamma^a X = +X (gamma^a)^T multiples of Gamma C")
```

The independent derivation of Section 5.28 ("the same two matrices from the transposition rules"). For $\gamma^a X - \zeta X(\gamma^a)^T = 0$ the coefficient matrix is $\mathrm{kron}(\gamma^a, 1) - \zeta\,\mathrm{kron}(1, ((\gamma^a)^T)^T)$, and $((\gamma^a)^T)^T = \gamma^a$, which is why the second Kronecker factor is the gamma itself. The printed line reports one solution for each sign, and the check confirms that they are proportional to C and to ΓC.

In [6], the picture of the three matrices.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
heat_map(axes[0], calC_plus, r"$\mathcal{C}_+ = C$")
heat_map(axes[1], Gamma, r"$\Gamma$", row_label=False)
image = heat_map(axes[2], calC_minus, r"$\mathcal{C}_- = \Gamma C$",
                 row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "conjugation_matrices",
            ...)
```

Three heat maps and a colour bar. **What figure 05c.2 shows**: $\mathcal{C}_+ = C$ with blue squares in the pattern of σ in the top-left block and red ones in the bottom-right block; Γ, blue then red on the diagonal; and $\mathcal{C}_- = \Gamma C$, red in the pattern of σ in both diagonal blocks. The student should see that multiplying by Γ only reverses the signs of the rows 1 to 8, and that all three pictures are mirror-symmetric about the diagonal (all three matrices are symmetric).

In [7], the conjugate fields of a complex column.

```
k = np.arange(16)  # 0, 1, ..., 15
PSI0 = (k % 4 - 1) + 1j * (k % 3 - 1)  # a fixed complex column with small entries
say("Psi_0 = " + ", ".join(f"{z.real:+.0f}{z.imag:+.0f}i" for z in PSI0[:8]) + ",")
say("        " + ", ".join(f"{z.real:+.0f}{z.imag:+.0f}i" for z in PSI0[8:]))
```

A fixed complex column Ψ_0: its component number k (counted from 0) is $(k \bmod 4) - 1 + i\,((k \bmod 3) - 1)$, where `%` gives the remainder of a division. Operations on the array `k` act on all 16 entries at once. The two printed lines list the components in the form $a + bi$ (`:+.0f` writes a number with its sign and no decimals): $-1 - 1i, +0 + 0i, +1 + 1i, +2 - 1i, \ldots$.

```
psibar_T = C @ PSI0.conj()  # (Psi^dagger C)^T = C^T Psi* = C Psi*
check(np.array_equal(calC_plus @ psibar_T, PSI0.conj())
      and np.array_equal(calC_minus @ psibar_T, Gamma @ PSI0.conj()),
      "Psi^c = calC_+ Psibar^T = Psi* and Psi^c = calC_- Psibar^T = Gamma Psi*")
```

$\bar{\Psi}^T = C\Psi^*$ (Section 5.28) is computed for this column, and the check confirms the two formulas $\mathcal{C}_+\bar{\Psi}^T = \Psi^*$ and $\mathcal{C}_-\bar{\Psi}^T = \Gamma\Psi^*$ of Theorem CC (b), entry by entry.

In [8], which mass each field solves with, exactly.

```
x4, m = sp.symbols("x4 m", real=True)  # the time and the mass, real numbers
psi0 = sp.Matrix([sp.Integer(int(z.real)) + sp.I * sp.Integer(int(z.imag))
                  for z in PSI0])
G4 = sp.Matrix(gamma["x4"].tolist())  # gamma^(x4) as an exact sympy matrix
GAMMA = sp.Matrix(Gamma.tolist())
```

`sp.symbols("x4 m", real=True)` makes two sympy symbols, the time and the mass, declared real (so that sympy knows that their conjugates are themselves). `psi0` is Ψ_0 with exact whole-number real and imaginary parts (`sp.I` is sympy's i); `G4` and `GAMMA` are $\gamma^{(x4)}$ and Γ as exact sympy matrices.

```
psi = sp.cos(m * x4) * psi0 - sp.sin(m * x4) * G4 * psi0  # the solution
fields = {"Psi": psi, "Psi* (calC_+)": psi.conjugate(),
          "Gamma Psi* (calC_-)": GAMMA * psi.conjugate()}
solves = {}  # (field, mass sign) -> True when the residual is exactly zero
```

`psi` is the free solution $\Psi(x4) = \cos(m\,x4)\Psi_0 - \sin(m\,x4)\gamma^{(x4)}\Psi_0$ of Section 5.28, as a column of 16 exact expressions. `fields` collects it and its two images, Ψ^* (`conjugate()`) and $\Gamma\Psi^*$, under readable names.

```
for name, phi in fields.items():
    for sign in (+1, -1):
        residual = (G4 * phi.diff(x4) - sign * m * phi).applyfunc(sp.expand)
        solves[(name, sign)] = residual == sp.zeros(16, 1)
    say(f"{name:20} solves with +m: {solves[(name, 1)]!s:5}  "
        f"with -m: {solves[(name, -1)]!s:5}")
```

For each field Φ and each sign, the **residual** $\gamma^{(x4)}d\Phi/dx4 - (\pm m)\Phi$ is computed (`diff(x4)` differentiates every component); it is zero exactly when Φ solves the equation with that mass. `applyfunc(sp.expand)` multiplies out every component, and the comparison with the zero column `sp.zeros(16, 1)` is exact. Each printed line shows, for one field, True or False for $+m$ and $-m$ (`!s` writes the value as text, `:5` pads it to five characters).

```
expected = {("Psi", 1): True, ("Psi", -1): False,
            ("Psi* (calC_+)", 1): True, ("Psi* (calC_+)", -1): False,
            ("Gamma Psi* (calC_-)", 1): False, ("Gamma Psi* (calC_-)", -1): True}
check(solves == expected,
      "exactly: Psi and Psi* solve with +m, Gamma Psi* solves with -m")
```

The prediction of Section 5.28 is written down and compared with the six results: Ψ and Ψ^* solve with $+m$ only, $\Gamma\Psi^*$ with $-m$ only. The printed lines (True False, True False, False True) agree.

In [9], the same with numbers on 801 time points.

```
t = np.linspace(0.0, 4.0 * np.pi, 801)  # the time x4 in units of 1/m, m = 1
g4 = gamma["x4"].astype(float)
cos_t, sin_t = np.cos(t)[:, None], np.sin(t)[:, None]  # columns for broadcasting
psi_t = cos_t * PSI0 - sin_t * np.einsum("rc,c->r", g4, PSI0)  # row t: Psi(x4_t)
dpsi_t = -sin_t * PSI0 - cos_t * np.einsum("rc,c->r", g4, PSI0)  # dPsi/dx4
```

With $m = 1$ the time is measured in units of $1/m$. `t` holds 801 times from 0 to 4π. `[:, None]` turns a list of 801 numbers into a column of 801 rows, so that `cos_t * PSI0` multiplies each row of 16 components by its own number (numpy's **broadcasting**: an array with one column is repeated along the missing direction). `np.einsum("rc,c->r", g4, PSI0)` is the column $\gamma^{(x4)}\Psi_0$. So `psi_t` has one row per time, the solution at that time, and `dpsi_t` its derivative, $-\sin t\,\Psi_0 - \cos t\,\gamma^{(x4)}\Psi_0$.

```
numeric = {"Psi": (psi_t, dpsi_t),
           "Psi* (calC_+)": (psi_t.conj(), dpsi_t.conj()),
           "Gamma Psi* (calC_-)": (psi_t.conj() @ Gamma.T, dpsi_t.conj() @ Gamma.T)}
largest = {}  # (field, sign) -> largest size of the residual over the 801 points
```

The three fields with their derivatives. For a field stored as rows, multiplying every row by Γ is done by `@ Gamma.T`: a row u^T times Γ^T is the transpose of the column Γu.

```
for name, (phi, dphi) in numeric.items():
    for sign in (+1, -1):
        residual = np.einsum("rc,tc->tr", g4, dphi) - sign * 1.0 * phi
        largest[(name, sign)] = float(np.max(np.linalg.norm(residual, axis=1)))
    shown = {sign: (f"{largest[(name, sign)]:.2f}" if largest[(name, sign)] > 1e-12
                    else "below 1e-12") for sign in (1, -1)}  # rounding-proof text
    say(f"{name:20} largest residual with +m: {shown[1]:11}, with -m: {shown[-1]}")
```

For each field and sign the residual $\gamma^{(x4)}d\Phi/dx4 \mp \Phi$ is computed at all 801 times at once (`"rc,tc->tr"` multiplies $\gamma^{(x4)}$ with the column of every time t). `np.linalg.norm(..., axis=1)` is the length of the residual at each time, and the largest one is kept. A tiny residual is printed as the words below 1e-12 rather than as a number, because its last digits depend on the computer. The printed lines show below 1e-12 where the exact computation said True, and 11.83 where it said False.

```
check(all((largest[key] < 1e-12) == solves[key] for key in solves),
      "the numerical residuals agree with the exact result")
```

The check: a residual below 10^{-12} exactly where the exact computation found a solution.

In [10], the picture of the three fields.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharey=True)
styles = {"Psi": ("#2a78d6", "-"), "Psi* (calC_+)": ("#eb6834", "--"),
          "Gamma Psi* (calC_-)": ("#1baf7a", ":")}
labels = {"Psi": r"$\Psi$", "Psi* (calC_+)": r"$\Psi^c_+ = \Psi^*$",
          "Gamma Psi* (calC_-)": r"$\Psi^c_- = \Gamma\Psi^*$"}
```

Two pictures that share the vertical axis (`sharey=True`), and for each field a colour, a line style (solid, dashed, dotted) and a legend label.

```
for name, (phi, _) in numeric.items():
    color, line = styles[name]
    axes[0].plot(t, phi[:, 0].real, color=color, linestyle=line, linewidth=2,
                 label=labels[name])
    axes[1].plot(t, phi[:, 0].imag, color=color, linestyle=line, linewidth=2,
                 label=labels[name])
```

For each field, the real part (left) and the imaginary part (right) of its first component (`phi[:, 0]` is column 0 of the rows, that is component 1 at every time) is drawn against the time. The derivative is not needed here, so it gets the throw-away name `_`.

```
for ax, part in zip(axes, ["real part", "imaginary part"]):
    ax.set_xticks([0, np.pi, 2 * np.pi, 3 * np.pi, 4 * np.pi],
                  ["0", r"$\pi$", r"$2\pi$", r"$3\pi$", r"$4\pi$"])
    ax.set_xlabel("time $x4$ (in units of $1/m$)")
    ax.set_title(f"component 1, {part}")
axes[0].set_ylabel("value of the component")
axes[1].legend(loc="upper center", bbox_to_anchor=(-0.05, -0.17), ncol=3)
save_figure(fig, "conjugate_solutions",
            ...)
```

Tick marks at multiples of π, axis labels and titles; one legend with three columns below both pictures. **What figure 05c.3 shows**: on the left the real part of Ψ^* (dashed) lies on that of Ψ (solid), and that of $\Gamma\Psi^*$ (dotted) is its mirror image; on the right the imaginary part of Ψ^* is the mirror image of that of Ψ, and that of $\Gamma\Psi^*$ lies on it. The reason: Ψ^* reverses the imaginary part, and Γ (which is -1 on the first half) reverses component 1 once more.

In [11], the table of the largest residuals.

```
from matplotlib.patches import Patch  # a coloured square for a legend

names = list(numeric)
table = np.array([[largest[(name, 1)], largest[(name, -1)]] for name in names])
fig, ax = plt.subplots(figsize=(7.0, 3.6))
solved = table < 1e-12  # True where the field solves the equation
ax.imshow(np.where(solved, 1.0, 0.0), cmap=LinearSegmentedColormap.from_list(
    "solve", ["#f0efec", "#2a78d6"]), vmin=0, vmax=1, aspect="auto")
```

The six largest residuals form a table of three rows (fields) and two columns (masses). `solved` is true where the residual is below 10^{-12}; `np.where(solved, 1.0, 0.0)` turns it into ones and zeros, drawn blue and grey with a two-colour map made on the spot.

```
for r in range(3):
    for c in range(2):
        text = "solves" if solved[r, c] else f"no ({table[r, c]:.2f})"
        ax.text(c, r, text, ha="center", va="center",
                color="white" if solved[r, c] else "black", fontweight="bold")
ax.axhline(0.5, color="white", linewidth=2)
ax.axhline(1.5, color="white", linewidth=2)
ax.axvline(0.5, color="white", linewidth=2)
ax.set_xticks([0, 1], ["mass $+m$", "mass $-m$"])
ax.set_yticks(range(3), [labels[name] for name in names])
ax.set_title("Largest residual of the field equation on $0 \\leq x4 \\leq 4\\pi$")
ax.legend(handles=[Patch(color="#2a78d6", label="residual below $10^{-12}$"),
                   Patch(color="#f0efec", label="residual of order 1")],
          loc="upper center", bbox_to_anchor=(0.5, -0.14), ncol=2)
ax.grid(False)
save_figure(fig, "which_mass",
            ...)
```

Each square gets the word solves or the word no with the residual; white lines separate the squares; the labels name the masses and the fields; a legend made of two coloured squares (`Patch`) goes below the picture. **What figure 05c.4 shows**: blue squares solves for Ψ and Ψ^* under $+m$ and for $\Gamma\Psi^*$ under $-m$, grey squares no (11.83) in the other three places: $\mathcal{C}_+$ keeps the mass, $\mathcal{C}_-$ reverses it.

In [12], the scalar and the charge density of the three fields.

```
bilinears = {}  # field -> (S at every time point, J^(x4) at every time point)
for name, (phi, _) in numeric.items():
    S_t = np.einsum("tr,rc,tc->t", phi.conj(), C, phi).real  # Psi^dagger C Psi
    J_t = np.einsum("tr,rc,tc->t", phi.conj(), B, phi).real  # Psi^dagger B Psi
    bilinears[name] = (S_t, J_t)
    say(f"{name:20} S from {S_t.min():+.6f} to {S_t.max():+.6f}; "
        f"J^(x4) from {J_t.min():+.6f} to {J_t.max():+.6f}")
```

For commuting components the scalar $S = \Psi^\dagger C \Psi$ and the charge density $J^{(x4)} = \Psi^\dagger B \Psi$ are computed at all 801 times (`"tr,rc,tc->t"` is $\sum_{r,c} \Psi^*_r K_{rc} \Psi_c$ for every time). Both are real (Section 5.4), and `.real` drops the imaginary part, which is zero up to rounding. Each printed line shows the smallest and the largest value over the times: S stays at -2 for all three fields, $J^{(x4)}$ at -6, $+6$ and -6. Both are constant. With $d\Psi/dx4 = -m\gamma^{(x4)}\Psi$ and $(\gamma^{(x4)}\Psi)^\dagger = \Psi^\dagger(\gamma^{(x4)})^T$, the product rule gives $dS/dx4 = -m\Psi^\dagger\big((\gamma^{(x4)})^T C + C\gamma^{(x4)}\big)\Psi$, which is 0 because $(\gamma^{(x4)})^T = -\gamma^{(x4)}$ and $\gamma^{(x4)}$ commutes with C (C1); in the same way $dJ^{(x4)}/dx4 = -m\Psi^\dagger\big((\gamma^{(x4)})^T B + B\gamma^{(x4)}\big)\Psi = 0$, because $(\gamma^{(x4)})^T B = iC\gamma^{(x4)}\gamma^{(x4)} = -iC$ and $B\gamma^{(x4)} = -iC\gamma^{(x4)}\gamma^{(x4)} = iC$.

```
S_psi, J_psi = bilinears["Psi"][0][0], bilinears["Psi"][1][0]
report("S of the solution Psi", f"{S_psi:+.6f}")
report("J^(x4) of the solution Psi", f"{J_psi:+.6f}")
constant = all(np.ptp(v) < 1e-12 for pair in bilinears.values() for v in pair)
```

The values of Ψ at the first time point, $x4 = 0$, are printed as two RESULT lines: $S = -2.000000$ and $J^{(x4)} = -6.000000$. `np.ptp` (peak to peak) is the largest minus the smallest value; `constant` is true when it is below 10^{-12} for all six lists.

```
# The values at x4 = 0, where Psi = Psi_0, are quoted in the caption of the next
# figure. Psi_0 has whole-number real and imaginary parts and C, B have entries 0,
# +-1, +-i, so S = Psi_0^dagger C Psi_0 and J^(x4) = Psi_0^dagger B Psi_0 are
# computed exactly (small whole numbers are stored without rounding).
S_exact = PSI0.conj() @ C @ PSI0
J_exact = PSI0.conj() @ B @ PSI0
check(S_exact == -2 and J_exact == -6 and S_psi == -2 and J_psi == -6,
      "at x4 = 0 exactly: S = -2 and J^(x4) = -6 for the solution Psi")
```

The four comment lines state the reason that the next sentence gives in full. At $x4 = 0$ the solution is Ψ_0, whose real and imaginary parts are whole numbers; C and B have the entries 0, ± 1, $\pm i$; so $\Psi_0^\dagger C \Psi_0$ and $\Psi_0^\dagger B \Psi_0$ are computed exactly (small whole numbers are stored without rounding). The check requires -2 and -6 exactly, the numbers quoted in the caption of the next figure.

```
check(constant and abs(S_psi) > 1 and abs(J_psi) > 1
      and np.allclose(bilinears["Psi* (calC_+)"][0], S_psi)
      and np.allclose(bilinears["Psi* (calC_+)"][1], -J_psi)
      and np.allclose(bilinears["Gamma Psi* (calC_-)"][0], S_psi)
      and np.allclose(bilinears["Gamma Psi* (calC_-)"][1], J_psi),
      "commuting components: Psi* keeps S and reverses J; Gamma Psi* keeps S and J")
```

The commuting rows of the sign table of Section 5.29, on this solution: all values constant, not zero (so that a sign can be seen), Ψ^* with the same S and the opposite $J^{(x4)}$, $\Gamma\Psi^*$ with the same S and the same $J^{(x4)}$.

In [13], the bar picture of S and J.

```
fig, ax = plt.subplots(figsize=(8.0, 4.2))
width = 0.26  # the width of one bar
for j, name in enumerate(names):
    color, _ = styles[name]
    values = [bilinears[name][0][0], bilinears[name][1][0]]
    bars = ax.bar(np.arange(2) + (j - 1) * width, values, width, color=color,
                  edgecolor="white", linewidth=2, label=labels[name])
    for bar, v in zip(bars, values):
        ax.text(bar.get_x() + bar.get_width() / 2, v + (0.3 if v > 0 else -0.7),
                f"{v:+.0f}", ha="center")
```

Two groups of three bars: at the position 0 the scalar, at 1 the charge density; the three fields are shifted by -1, 0, $+1$ bar widths. Each bar gets its value written just above (positive) or below (negative) it; `bar.get_x() + bar.get_width() / 2` is the middle of the bar.

```
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks([0, 1], [r"scalar $S = \Psi^\dagger C\Psi$",
                       r"charge density $J^{(x4)} = \Psi^\dagger B\Psi$"])
```

```
ax.set_ylabel("value (constant along $x4$)")
ax.set_ylim(-8, 8)
ax.set_title("Commuting components: what the two conjugations do to S and J")
ax.legend(loc="upper left")
save_figure(fig, "bilinears",
            ...)
```

The zero line, the labels of the two groups, the vertical range from -8 to 8, the title and the legend. **What figure 05c.5 shows**: three bars at -2 in the left group; in the right group -6 (blue, Ψ), $+6$ (orange, Ψ^*) and -6 (aqua, $\Gamma\Psi^*$). For commuting components $\mathcal{C}_+$ reverses the charge and keeps the mass; $\mathcal{C}_-$ keeps the charge and reverses the mass.

In [14], the sign table.

```
K_S = C.astype(complex)  # the matrix of the scalar S
K_J = [-1j * (C @ gamma[x]) for x in COORDS]  # the matrices of the currents J^a

def sign_of(M, K, eps):
    new = eps * (M.conj().T @ K @ M).T
    return 1 if np.array_equal(new, K) else (-1 if np.array_equal(new, -K) else 0)
```

The matrices of the scalar and of the eight currents, and `sign_of(M, K, eps)`, which computes $K' = \epsilon(M^\dagger K M)^T$ of Section 5.29 and returns $+1$ if $K' = K$, -1 if $K' = -K$, and 0 otherwise. The comparisons are exact, because all entries are 0, ± 1 or $\pm i$.

```
measured = {}  # the record's keys, e.g. "plus,eps=1" -> [sign of S, [signs of J]]
for map_name, M in (("plus", I16), ("minus", Gamma)):
    for eps in (1, -1):
        measured[f"{map_name},eps={eps}"] = [
            sign_of(M, K_S, eps), [sign_of(M, K, eps) for K in K_J]]
for key, (sign_S, signs_J) in measured.items():
    say(f"{key:13} S -> {sign_S:+d} S;  J^a -> s J^a with s = "
        + " ".join(f"{s:+d}" for s in signs_J))
```

For the two maps ($M = 1$ and $M = \Gamma$) and the two kinds of components the signs are collected under the keys that the record uses, for example `plus,eps=1`. The four printed lines are the four rows of the table of Section 5.29: `plus,eps=1` $+1$ and eight times -1; `plus,eps=-1` -1 and eight times $+1$; `minus,eps=1` $+1$ and eight times $+1$; `minus,eps=-1` -1 and eight times -1.

```
recorded_table = json.loads(detail("bilinears_under_charge_conjugation")
                            .split("measured: ", 1)[1])
check_reproduces(measured == recorded_table
                 and recorded("bilinears_under_charge_conjugation"),
                 "the signs of S and J under calC_+ and calC_-, commuting and "
                 "anticommuting, equal the recorded table",
                 record=f"{RECORD}, check bilinears_under_charge_conjugation")
```

The record's detail text ends with the word measured, a colon and the table in JSON form. `split("measured: ", 1)[1]` takes the text after these words, and `json.loads` turns it into a dictionary

of the same shape as `measured`. The check requires the two to be equal: the notebook and the record measured the same 36 signs.

In [15], the picture of the sign table.

```
row_keys = ["plus,eps=1", "plus,eps=-1", "minus,eps=1", "minus,eps=-1"]
row_names = [r"$\mathcal{C}_+$, commuting", r"$\mathcal{C}_+$, anticommuting",
             r"$\mathcal{C}_-$, commuting", r"$\mathcal{C}_-$, anticommuting"]
grid = np.array([[measured[key][0]] + measured[key][1] for key in row_keys])
fig, ax = plt.subplots(figsize=(10.0, 3.8))
ax.imshow(grid, cmap=SIGNS, vmin=-1, vmax=1, aspect="auto")
```

The four rows of signs, each the sign of S followed by the eight signs of the currents (`[a] + list` puts one element in front of a list), form a 4×9 array, drawn with the colour map of the heat maps.

```
for r in range(4):
    for c in range(9):
        ax.text(c, r, f"{grid[r, c]:+d}", ha="center", va="center", color="white",
                fontweight="bold")
for k in range(1, 4):
    ax.axhline(k - 0.5, color="white", linewidth=2)
for k in range(1, 9):
    ax.axvline(k - 0.5, color="white", linewidth=3 if k == 1 else 2)
ax.set_xticks(range(9), ["$S$"] + [rf"$J^{{({x})}}$" for x in COORDS])
ax.set_yticks(range(4), row_names)
ax.set_title("Sign of each bilinear after the conjugation (red $+1$ kept, blue "
             "$-1$ reversed)")
ax.grid(False)
save_figure(fig, "sign_table",
            ...)
```

Each square gets its sign in bold white; white lines separate the squares, with a thicker line between the column S and the currents; the columns are labelled S, $J^{(x0)}, \ldots, J^{(x7)}$ (the doubled braces of the `rf`-string give single braces) and the rows by map and kind of component. **What figure 05c.6 shows**: the row $\mathcal{C}_+$, commuting is red for S and blue for all currents; the row $\mathcal{C}_-$, commuting is red everywhere; each anticommuting row is the commuting row above it with every colour reversed. The student should see that the exchange of two anticommuting components flips every sign once more.

In [16], the reality conditions.

```
check_reproduces(np.array_equal(I16 @ np.conj(I16), I16)
                 and np.array_equal(Gamma @ np.conj(Gamma), I16)
                 and recorded("majorana_conditions_consistent"),
                 "M M* = 1 for M = 1 and M = Gamma: both reality conditions are "
                 "consistent",
                 record=f"{RECORD}, check majorana_conditions_consistent")
```

The consistency condition $MM^* = 1$ of Section 5.29 for $M = 1$ and $M = \Gamma$.

In [17], the reality conditions in time.

```
start_real = PSI0.real.astype(complex)  # obeys Psi_0* = Psi_0
start_gamma = np.concatenate([1j * PSI0.imag[:8], PSI0.real[8:]])  # first half
start_gamma = start_gamma / np.linalg.norm(start_gamma)  # imaginary, size 1
start_real = start_real / np.linalg.norm(start_real)  # size 1
check(np.allclose(start_gamma, Gamma @ start_gamma.conj())
      and np.allclose(start_real, start_real.conj()),
      "the two starting columns obey Psi_0 = Gamma Psi_0* and Psi_0 = Psi_0*")
```

Two starting columns of length 1: the real part of Ψ_0, which obeys $\Psi_0 = \Psi_0^*$; and a column whose first half is i times the imaginary parts of the first eight components of Ψ_0 and whose second half is the real parts of the last eight (`np.concatenate` joins two arrays), which obeys $\Psi_0 = \Gamma\Psi_0^*$. Dividing by `np.linalg.norm` (the length) makes the length 1. The check confirms the two conditions.

```
def evolve(start, mass):
    return (np.cos(mass * t)[:, None] * start
            - np.sin(mass * t)[:, None] * np.einsum("rc,c->r", g4, start))
```

`evolve(start, mass)` is the free solution with the given starting column and mass at all 801 times, one row per time.

```
violation = {}  # (condition, mass) -> size of the violation at every time
for mass in (1.0, 0.5, 0.0):
    f_real = evolve(start_real, mass)
    f_gamma = evolve(start_gamma, mass)
    violation[("real", mass)] = np.linalg.norm(f_real - f_real.conj(), axis=1)
    violation[("gamma", mass)] = np.linalg.norm(f_gamma - f_gamma.conj() @ Gamma.T,
                                                axis=1)
```

For the masses 1, 0.5 and 0 both solutions are computed, and at each time the length of $\Psi - \Psi^*$ (the violation of the real condition) and of $\Psi - \Gamma\Psi^*$ (the violation of the other one).

```
check(all(np.max(violation[("real", mass)]) < 1e-12 for mass in (1.0, 0.5, 0.0))
      and np.max(violation[("gamma", 0.0)]) < 1e-12
      and np.allclose(violation[("gamma", 1.0)], 2 * np.abs(np.sin(t)))
      and np.allclose(violation[("gamma", 0.5)], 2 * np.abs(np.sin(0.5 * t))),
      "Psi = Psi* is kept in time; Psi = Gamma Psi* is violated by 2 |sin(m x4)|")
```

The prediction of Section 5.29: the real condition is never violated; the other is violated by exactly $2|\sin(m\,x4)|$ (the starting column has length 1), which is zero only for $m = 0$.

```
fig, ax = plt.subplots(figsize=(8.0, 4.2))
ax.plot(t, violation[("gamma", 1.0)], color="#eb6834", linewidth=2,
        label=r"$|\Psi - \Gamma\Psi^*|$, $m = 1$")
ax.plot(t, violation[("gamma", 0.5)], color="#eda100", linewidth=2, linestyle="--",
        label=r"$|\Psi - \Gamma\Psi^*|$, $m = 0.5$")
ax.plot(t, violation[("gamma", 0.0)], color="#4a3aa7", linewidth=3, linestyle="-.",
        label=r"$|\Psi - \Gamma\Psi^*|$, $m = 0$")
ax.plot(t, violation[("real", 1.0)], color="#2a78d6", linewidth=2, linestyle=":",
        label=r"$|\Psi - \Psi^*|$, $m = 1$ (real start)")
```

Four curves: the violation of $\Psi = \Gamma\Psi^*$ for the three masses (solid, dashed, dash-dotted) and that of the real condition for $m = 1$ (dotted).

```
ax.set_xticks([0, np.pi, 2 * np.pi, 3 * np.pi, 4 * np.pi],
              ["0", r"$\pi$", r"$2\pi$", r"$3\pi$", r"$4\pi$"])
ax.set_xlabel("time $x4$")
ax.set_ylabel("size of the violation")
ax.set_ylim(-0.1, 2.4)
ax.annotate("the dash-dotted and the dotted curve are exactly 0 at all times",
            (2.5 * np.pi, 0.0), xytext=(2.0 * np.pi, 0.35), ha="center",
            arrowprops={"arrowstyle": "->", "color": "black"},
            bbox={"facecolor": "white", "edgecolor": "#52514e"})
ax.set_title("Which reality condition survives the time evolution")
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.17), ncol=2)
save_figure(fig, "reality_in_time",
            ...)
```

Tick marks, labels, the vertical range, and an **annotation**: a text in a white box with an arrow pointing at the place $(2.5\pi, 0)$, where two curves lie on the axis and would otherwise be hard to see. **What figure 05c.7 shows**: the solid curve $2|\sin x4|$ with arches of height 2, the dashed curve $2|\sin(x4/2)|$ with arches twice as wide, and two curves lying exactly on zero: the real field stays real, and the condition of the mass-reversing conjugation survives only for $m = 0$.

In [18], real fields.

```
r = sp.Matrix(sp.symbols("r1:17", real=True))  # a general real column
currents = [sp.expand((-sp.I * r.T * sp.Matrix((C @ gamma[x]).tolist()) * r)[0, 0])
            for x in COORDS]
say("J^a of a general real column, a = x0..x7: " + ", ".join(map(str, currents)))
```

`sp.symbols("r1:17", real=True)` makes the 16 real symbols $r_1, \ldots, r_{16}$, and `r` is the column of them: all real columns at once. For each direction the current $J^a = -i\, r^T C\gamma^a r$ is multiplied out (`[0, 0]` takes the single entry of the 1×1 result). The printed line shows eight zeros: fact (F1) of Section 5.29.

```
S_change = sp.expand((GAMMA * r).T * sp.Matrix(C.tolist()) * (GAMMA * r)
                     - r.T * sp.Matrix(C.tolist()) * r)[0, 0]
kinetic_reversed = all(np.array_equal(Gamma.T @ C @ gamma[x] @ Gamma,
                                      -(C @ gamma[x])) for x in COORDS)
```

`S_change` is $S(\Gamma r) - S(r)$ for the general real column, multiplied out; it must be 0. `kinetic_reversed` checks $\Gamma^T C\gamma^a\Gamma = -C\gamma^a$ for the eight directions, (X8).

```
psi0_real = psi0.applyfunc(sp.re)  # the real part of every component of Psi_0
psi_real = sp.cos(m * x4) * psi0_real - sp.sin(m * x4) * G4 * psi0_real
image = GAMMA * psi_real  # the real field Gamma Psi
image_solves_minus = (G4 * image.diff(x4) + m * image).applyfunc(sp.expand) \
    == sp.zeros(16, 1)
```

The real free solution that starts at the real part of Ψ_0 (`sp.re` is the real part), its image $\Gamma\Psi$, and the exact test whether the image solves the equation with $-m$: the residual $\gamma^{(x4)} d\Phi/dx4 + m\Phi$ must vanish. A backslash at the end of a line continues the statement on the next line.

```
check_reproduces(all(c == 0 for c in currents) and S_change == 0 and kinetic_reversed
                 and psi_real.conjugate() == psi_real and image_solves_minus
                 and recorded("real_fields_charge_conjugation"),
                 "real fields: J = 0, calC_+ is the identity, Gamma keeps S, reverses "
                 "the kinetic matrices and maps a solution with m to one with -m",
                 record=f"{RECORD}, check real_fields_charge_conjugation")
```

The three facts (F1) to (F3) of Section 5.29 in one check: the currents vanish, the real solution equals its conjugate (so $\mathcal{C}_+$ acts as the identity on it), Γ keeps S, reverses the kinetic matrices, and maps the real solution with mass m to a real solution with mass $-m$.

In [19], the picture of a real field.

```
real_t = evolve(PSI0.real.astype(complex), 1.0).real  # the real solution, m = 1
gamma_t = real_t @ Gamma.T  # Gamma Psi at every time
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharey=True)
```

The real solution for $m = 1$ at the 801 times (the starting column is not normalised here), and its image under Γ; two pictures with a shared vertical axis.

```
for ax, comp in zip(axes, [0, 8]):
    ax.plot(t, real_t[:, comp], color="#2a78d6", linewidth=3,
            label=r"real solution $\Psi$ (mass $m$)")
    ax.plot(t, real_t[:, comp], color="#eb6834", linewidth=2, linestyle="--",
            label=r"$\Psi^c_+ = \Psi^* = \Psi$ (identical)")
    ax.plot(t, gamma_t[:, comp], color="#1baf7a", linewidth=2, linestyle=":",
            label=r"$\Gamma\Psi$ (solves with mass $-m$)")
    ax.set_xticks([0, np.pi, 2 * np.pi, 3 * np.pi, 4 * np.pi],
                  ["0", r"$\pi$", r"$2\pi$", r"$3\pi$", r"$4\pi$"])
    ax.set_xlabel("time $x4$ (in units of $1/m$)")
    half = "first" if comp < 8 else "second"  # components 1-8 or 9-16
    ax.set_title(f"component {comp + 1} ({half} half)")
```

For component 1 (left; Python's index 0) and component 9 (right; index 8) three curves are drawn: the real solution (thick, solid), its $\mathcal{C}_+$ image, which is the same curve (dashed on top of it), and its Γ image (dotted). The title names the component and its half.

```
axes[0].set_ylabel("value of the component")
axes[1].text(2.0 * np.pi, 0.0, "all three curves coincide:\n"
             r"$\Gamma = +1$ on the second half", ha="center", va="center",
             bbox={"facecolor": "white", "edgecolor": "#52514e"})
axes[1].legend(loc="upper center", bbox_to_anchor=(-0.05, -0.17), ncol=3)
save_figure(fig, "real_field",
            ...)
```

A text box in the right picture explains why only one curve is visible there, and one legend goes below both pictures. **What figure 05c.8 shows**: on the left the dashed curve lies exactly on the solid one, and the dotted curve is their mirror image; on the right all three coincide. For a real field the same-mass conjugation does nothing; of the two charge-conjugation matrices, the only one that changes a real field is ΓC, whose map $\Psi \to \Gamma\Psi$ flips the first half and belongs to the mass $-m$.

In [20], the quantised field.

```
q_plus = I16 @ B.T @ I16.conj().T  # M = 1
q_minus = Gamma @ B.T @ Gamma.conj().T  # M = Gamma
say(f"B^T = -B: {np.array_equal(B.T, -B)};  1 B^T 1 = B: "
    f"{np.array_equal(q_plus, B)};  Gamma B^T Gamma^dagger = B: "
    f"{np.array_equal(q_minus, B)}")
```

The test of Section 5.34: a map $\Psi \to M\Psi^{\dagger T}$ of the quantised field keeps the canonical anticommutator exactly when $MB^TM^\dagger = B$. The cell computes $MB^TM^\dagger$ for $M = 1$ and $M = \Gamma$. The printed line shows True for $B^T = -B$, False for $M = 1$ and True for $M = \Gamma$.

```
check_reproduces(np.array_equal(q_minus, B) and np.array_equal(q_plus, -B)
                 and recorded("quantum_charge_conjugation_unitary_type"),
                 "M B^T M^dagger = B for M = Gamma and = -B for M = 1: the conjugation "
                 "of the quantised field is Psi -> Gamma Psi^(dagger T), which reverses "
                 "the mass",
                 record=f"{RECORD}, check quantum_charge_conjugation_unitary_type")
```

The check reproduces the record: $\Gamma B^T\Gamma^\dagger = B$, while $M = 1$ gives $-B$.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
heat_map(axes[0], B.imag, "imaginary part of $B$")
heat_map(axes[1], q_plus.imag, r"imaginary part of $1\,B^T 1$", row_label=False)
image = heat_map(axes[2], q_minus.imag, r"imaginary part of $\Gamma B^T\Gamma$",
                 row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "quantum_b",
            ...)
```

Three heat maps of imaginary parts (the real parts are zero). **What figure 05c.9 shows**: the middle picture has every colour of the left one reversed ($B^T = -B$), while the right picture equals the left one: of the two maps, only $\Psi \to \Gamma\Psi^{\dagger T}$ keeps the canonical rule.

In [21], the last check.

```
FIGURES = ["05c_1_solution_spaces.png", "05c_2_conjugation_matrices.png",
           "05c_3_conjugate_solutions.png", "05c_4_which_mass.png",
           "05c_5_bilinears.png", "05c_6_sign_table.png",
           "05c_7_reality_in_time.png", "05c_8_real_field.png", "05c_9_quantum_b.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the nine figure files of notebook 05c exist")
all_checks_passed()
```

The nine figure files must exist, and the last line reads ALL 20 CHECKS PASSED (notebook 05c): two checks in In [2], two in In [3], one in In [4], three in In [5], one in In [7], one in In [8], one in In [9], two in In [12], one in In [14], one in In [16], two in In [17], one in In [18], one in In [20] and one in In [21]. Ten of them reproduce checks of the lead report (the two of In [2], the two of In [3], the first two of In [5], and those of In [14], In [16], In [18] and In [20]); the other ten are the notebook's own computations. The two lead checks that the notebook does not repeat are `spinor_connection_real` and `u1_noether_matrix_identity`, which need the curved metric (Chapters 6 and 21); they are made at $b_4 = 1$, and `Revision/theory/reports/python-field-theory-b4.json` makes both for a general b_4 (checks `spinor_connection_real_b4` and `u1_noether_matrix_identity_b4`).

5.34 The quantised field: operators, the indefinite form and normal ordering

The field dirac16complex is **quantised** (Chapter 10 does this in full): its 16 components become operators, and a charge conjugation of the quantised field must be a map of operators that keeps the basic rule of the quantum theory. This section explains the few words of quantum theory that are needed, from zero, and then derives which conjugation survives and what it does to the scalar and to the currents. Notebook 05e computes every statement on an explicit computer model with $2^{16} = 65536$ quantum states.

Operators, anticommutators, modes. In quantum theory a **state** is a column of numbers, and an **operator** is a rule that turns a state into another state; here every operator is a (big) matrix acting on columns. Operators are multiplied by doing one after the other, and the order matters. The **anticommutator** of two operators is $\{X, Y\} = XY + YX$. A **fermion mode** is a place that holds zero or one particle. With n modes a basic state is a **pattern** of n occupations, each 0 or 1, so there are 2^n patterns; all combinations of them form the **Fock space**. The **annihilation operator** f_p empties mode p (and gives zero if it is empty), and the **creation operator** f_p^* fills it (zero if it is full), each with the sign $(-1)^{n_{<p}}$, where $n_{<p}$ is the number of occupied modes below p. Example with two modes 0 and 1: write the patterns as $|00\rangle$ (both empty), $|10\rangle$ (mode 0 full), $|01\rangle$ (mode 1 full) and $|11\rangle$ (both full). Then $f_0|11\rangle = |01\rangle$ (no mode below 0), while $f_1|11\rangle = -|10\rangle$ (mode 0 below is full). Because of this sign, operators of different modes **anticommute**; together these rules give the **canonical anticommutation relations**

$$\{f_p, f_q^*\} = \delta_{pq}, \qquad \{f_p, f_q\} = 0, \qquad \{f_p^*, f_q^*\} = 0,$$

where δ_{pq} is 1 for $p = q$ and 0 otherwise; in particular $f_p f_p = 0$: no mode holds two fermions. Check of one case: $f_0 f_1|11\rangle = f_0(-|10\rangle) = -|00\rangle$ and $f_1 f_0|11\rangle = f_1|01\rangle = |00\rangle$ (mode 0 is now empty, so no sign); the two add up to zero, $\{f_0, f_1\}|11\rangle = 0$. On the Fock space the ordinary inner product $\langle a|b\rangle = \sum_n a_n^* b_n$ is **positive**: $\langle a|a\rangle$ is a sum of squared sizes. The **Hilbert adjoint** X^* of an operator is the conjugate transpose of its matrix; f_p^* is the Hilbert adjoint of f_p. For every operator X and every state ϕ,

$$\langle\phi|\{X, X^*\}|\phi\rangle = \langle\phi|XX^*|\phi\rangle + \langle\phi|X^*X|\phi\rangle = |X^*\phi|^2 + |X\phi|^2 \geq 0,$$

because $\langle\phi|XY\phi\rangle = \langle X^*\phi|Y\phi\rangle$ (the defining property of the adjoint) and $|v|^2 = \langle v|v\rangle$ is a squared length. **The anticommutator of an operator with its Hilbert adjoint is never negative.**

Momentum, energy and the mode Hamiltonian. A few more words describe how a field changes along a direction and in time.

- A field of **one momentum** k along $x1$ is a field of the form $\Psi = \psi\, e^{ik\,x1}$: a column ψ (which may still depend on the time) times the number $e^{ik\,x1} = \cos(k\,x1) + i\sin(k\,x1)$, which goes once around the circle of complex numbers of size 1 each time $x1$ grows by $2\pi/k$. The real number k is the **momentum** of the field along $x1$. A momentum may have parts along several directions; when it has no part along the extra times $x5$, $x6$, $x7$, the field does not depend on them, and the record calls this the **good sector**. (Outside the good sector the record's check `mode_hamiltonian_good_sector` shows that the energy defined next can become imaginary and the field then grows exponentially in time; Chapters 8 and 10 treat this.)
- A column that depends on the time as $e^{-iE\,x4}$, with a real number E, has the **energy** E: the larger E, the faster the number $e^{-iE\,x4}$ goes around the circle of complex numbers of size 1 as the time $x4$ grows.

The record's example treats the field near one point of space as if the metric were flat there (its check `mode_hamiltonian_good_sector` calls these frozen-coefficient, flat-frame plane waves): the gammas of the curved space are replaced by the constant gammas and the spin connection is left out. For a free field ($V = m$) that depends only on $x4$ and $x1$, the field equation of Section 5.28 then keeps two terms, $\gamma^{(x4)}\partial_{x4}\Psi + \gamma^{(x1)}\partial_{x1}\Psi = m\Psi$. Insert $\Psi = u\,e^{i(k\,x1 - E\,x4)}$ with a constant column u. The derivative of e^{icy} with respect to y is $ic\,e^{icy}$ (differentiate $\cos(cy) + i\sin(cy)$ term by term), so ∂_{x4} brings down the factor $-iE$ and ∂_{x1} the factor ik; dividing by the nonzero number $e^{i(k\,x1 - E\,x4)}$ leaves $-iE\,\gamma^{(x4)}u + ik\,\gamma^{(x1)}u = mu$. Multiplying from the left by $-\gamma^{(x4)}$ and using $\gamma^{(x4)}\gamma^{(x4)} = -1$ gives $-iE\,u - ik\,\gamma^{(x4)}\gamma^{(x1)}u = -m\gamma^{(x4)}u$; multiplying by i gives $E\,u + k\,\gamma^{(x4)}\gamma^{(x1)}u = -im\gamma^{(x4)}u$, that is

$$E\,u = h\,u, \qquad h = -im\,\gamma^{(x4)} - k\,\gamma^{(x4)}\gamma^{(x1)}.$$

So the energies of the fields of one momentum k are the eigenvalues of the 16×16 matrix h, and the columns u are its **eigenvectors** (the columns $v \neq 0$ with $hv = Ev$, Rule 6 of Section 5.3). This matrix is called the **mode Hamiltonian** of the momentum k.

Two columns u and w are **orthonormal** when each has length 1 and they are perpendicular: $u^\dagger u = w^\dagger w = 1$ and $u^\dagger w = 0$. A list of columns is orthonormal when every two of them are.

The canonical rule of the record. The Revision record quantises dirac16complex with the canonical anticommutator on a slice of constant time $x4$,

$$\{\Psi_A(x), \Psi_C^\dagger(y)\} = B_{AC}\,\frac{\delta^7(x-y)}{\cos z},$$

where $\cos z$ is the volume factor ($z = 6Hx0$; the record writes its formulas for the author's metric at $b_4 = 1$, where $\sqrt{|g|} = b_4^{3/2}\cos z$ of Chapter 3 is $\cos z$) and $\delta^7(x-y)$ is the **delta function** of the seven other coordinates: an idealised object that is zero whenever the point x differs from the point y and whose integral over the seven coordinates is 1 (think of ever narrower and ever taller bumps of area 1). So operators at two different points of the slice anticommute, and only operators at the same point have a nonzero anticommutator (formula `quantisation` of `Revision`

`/theory/field-theory.json`; Chapter 10 derives it). For the operators of one single momentum, the record's exact Fock-space example, the delta function and the factor are absent and the rule reads $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$ for $A, C = 1, \ldots, 16$.

Why $\Psi^\dagger$ cannot be the Hilbert adjoint. Suppose $\Psi_A^\dagger$ were the Hilbert adjoint Ψ_A^*. Every diagonal entry of B is zero (the table of Section 5.6: row r of B/i never points to column r). So the rule would give $\{\Psi_A, \Psi_A^*\} = B_{AA} = 0$, and by the inequality above $|\Psi_A^*\phi|^2 + |\Psi_A\phi|^2 = 0$ for every state ϕ; a sum of two squared lengths is zero only when both are, so $\Psi_A\phi = 0$ for every ϕ: Ψ_A would be the zero operator. But row A of B contains a nonzero entry B_{AC}, and the anticommutator of the zero operator with anything is zero, not B_{AC}: a contradiction. The record makes the same argument with the column u that has $u_7 = -i/\sqrt{2}$, $u_{16} = 1/\sqrt{2}$ and zeros elsewhere, which obeys $Bu = -u$: the operator $X = \sum_A u_A^* \Psi_A$ has $\{X, X^\dagger\} = u^\dagger B u = -1 < 0$, impossible for a Hilbert adjoint (check `no_positive_inner_product` of `Revision/theory/reports/wolfram-field-theory.jso n`). So the canonical rule needs an **indefinite** inner product, one in which some states have negative squared length; a space with such a product is called a **Krein space** (Chapter 10).

The record's positive realisation. The record keeps the positive Fock space and writes $\Psi^\dagger = \chi B$, where χ is the Hilbert adjoint of Ψ. The record's example is one momentum in the good sector, with the mass $m = 3$ and the momentum $k = 4$ along $x1$. Its mode Hamiltonian, the matrix h derived above with $k = 4$, is

$$h = -im\,\gamma^{(x4)} - 4\,\gamma^{(x4)}\gamma^{(x1)}.$$

(The record gives the same matrix from the **energy density**, the energy per unit volume: it writes the energy density of one momentum k as $\Psi^\dagger(mC - iC\,k_a\gamma^a)\Psi = \chi h \Psi$, so $h = B(mC - iC\,k_a\gamma^a)$. With $BC = -iC\gamma^{(x4)}C = -i\gamma^{(x4)}$, because $C\gamma^{(x4)}C = -(\gamma^{(x4)})^T = \gamma^{(x4)}$ by (C5) and the antisymmetry of $\gamma^{(x4)}$, and with $k_{x1} = 4$ the only nonzero momentum, this is $h = -im\gamma^{(x4)} - 4i(-i\gamma^{(x4)})\gamma^{(x1)}$, the matrix above; check `mode_hamiltonian_Krein_selfadjoint` of `Revision/theory/reports/ wolfram-field-theory.json`.) Both terms are Hermitian ($\gamma^{(x4)}$ is real and antisymmetric, so $-i\gamma^{(x4)}$ is Hermitian; $\gamma^{(x4)}\gamma^{(x1)}$ is real and, by Rule 4 of Section 5.3, symmetric), they anticommute (Rule 1), and each squares to 1 ($(-i\gamma^{(x4)})^2 = -\gamma^{(x4)}\gamma^{(x4)} = 1$; $(\gamma^{(x4)}\gamma^{(x1)})^2 = -\eta_{x4\,x4}\eta_{x1\,x1}1 = 1$). Hence $hh = (m^2 + 4^2)1 = 25 \cdot 1$, and the eigenvalues of h are ± 5: the energy is $E = \sqrt{3^2 + 4^2} = 5$. Let $u_1, \ldots, u_8$ be orthonormal eigenvectors with $hu_s = 5u_s$ and $v_1, \ldots, v_8$ orthonormal eigenvectors with $hv_s = -5v_s$ (Notebook 05e constructs them). The 16 columns together are orthonormal, because an eigenvector u with the eigenvalue 5 and an eigenvector v with the eigenvalue -5 of the Hermitian matrix h are perpendicular: $5\,u^\dagger v = (hu)^\dagger v = u^\dagger h^\dagger v = u^\dagger h v = -5\,u^\dagger v$, so $10\,u^\dagger v = 0$. They form a matrix W with $W^\dagger W = 1$ (the entries of $W^\dagger W$ are the products $u^\dagger w$ of the columns, so $W^\dagger W = 1$ says exactly that the columns are orthonormal); $W^\dagger W = 1$ says that $W^\dagger$ is the inverse of the square matrix W, and then also $WW^\dagger = 1$. With eight particle modes b_s and eight antiparticle modes d_s (sixteen modes in all) the field operators are

$$\Psi_A = \sum_{s=1}^{8} \left((u_s)_A\, b_s + (v_s)_A\, d_s^*\right), \qquad \chi_A = \sum_{s=1}^{8} \left((u_s)_A^*\, b_s^* + (v_s)_A^*\, d_s\right), \qquad \Psi_A^\dagger = \sum_C \chi_C B_{CA}.$$

Line by line: by the canonical relations only the pairs (b_s, b_s^*) and (d_s^*, d_s) have a nonzero anticommutator, equal to 1, so

$$\{\Psi_A, \chi_C\} = \sum_s (u_s)_A (u_s)^*_C + \sum_s (v_s)_A (v_s)^*_C = (WW^\dagger)_{AC} = \delta_{AC},$$

and then $\{\Psi_A, \Psi^\dagger_C\} = \sum_D \{\Psi_A, \chi_D\} B_{DC} = B_{AC}$: the canonical rule holds. The record also computes the energy $\chi h \Psi$, whose value in the **vacuum** $|0\rangle$ (no mode occupied) is $-8E = -40$ (the eight negative-energy solutions form a filled **sea**), and, after **normal ordering** (the subtraction of the vacuum value, defined below), the energy $+5$ for each of the 16 one-quantum states $b^*_s|0\rangle$ and $d^*_s|0\rangle$, and the charge $\Psi^\dagger B \Psi$ equal to $+1$ for the eight particles and -1 for the eight antiparticles (check `Fock_space_good_sector_example`). Notebook 05e reproduces all of this.

Which conjugation keeps the rule. For a constant matrix M (real or complex) define the conjugated field $\Psi'_A = \sum_C M_{AC} \Psi^\dagger_C$, the operator form of $M\Psi^*$, written $\Psi' = M\Psi^{\dagger T}$. Its canonical conjugate is obtained by conjugating both sides (which conjugates the numbers): $\Psi'^\dagger_A = \sum_C M^*_{AC} \Psi_C$. Then, line by line,

$$\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{D,E} M_{AD} M^*_{CE} \{\Psi^\dagger_D, \Psi_E\} = \sum_{D,E} M_{AD} B_{ED} M^*_{CE} = (MB^T M^\dagger)_{AC}.$$

The first step expands both operators (numbers come out of an anticommutator); the second uses the canonical rule $\{\Psi^\dagger_D, \Psi_E\} = \{\Psi_E, \Psi^\dagger_D\} = B_{ED}$; the third reads the sum as a matrix product, since $B_{ED} = (B^T)_{DE}$ and $M^*_{CE} = (M^\dagger)_{EC}$. **The rule is kept exactly when $MB^T M^\dagger = B$.** Now B is Hermitian and purely imaginary, so $B^T = (B^\dagger)^* = B^* = -B$. For $M = 1$: $MB^T M^\dagger = B^T = -B$: the rule is broken. For $M = \Gamma$ (real, $\Gamma^\dagger = \Gamma^T = \Gamma$):

$$\Gamma B^T \Gamma = -\Gamma B \Gamma = -(-i)\, \Gamma C \gamma^{(x4)} \Gamma = i\, \Gamma^T C \gamma^{(x4)} \Gamma = i(-C\gamma^{(x4)}) = B,$$

by $B^T = -B$, the definition of B, (X6) and (X8). The matrices of Theorem CC are the multiples $\lambda 1$ and $\lambda\Gamma$, with any complex number $\lambda \neq 0$. A factor λ gives $(\lambda M) B^T (\lambda M)^\dagger = \lambda\lambda^*\, MB^T M^\dagger = |\lambda|^2\, MB^T M^\dagger$, because the conjugate transpose turns λ into λ^*. So $\lambda 1$ gives $-|\lambda|^2 B$, which is never B (that would need $(1 + |\lambda|^2)B = 0$), and $\lambda\Gamma$ gives $|\lambda|^2 B$, which is B exactly when $|\lambda| = 1$, that is when $\lambda = e^{i\alpha}$ is a **phase factor** (a complex number of size 1). **Among the matrices of Theorem CC, only $\Psi' = \Gamma\Psi^{\dagger T}$, up to a phase factor, keeps the canonical rule** (lead check `quantum_charge_conjugation_unitary_type` for $M = \Gamma$ and $M = 1$): the conjugation of the quantised field has the type of $\mathcal{C}_-$.

The conjugated bilinear, line by line. Let $X = \Psi^\dagger K \Psi = \sum_{A,C} \Psi^\dagger_A K_{AC} \Psi_C$ and $X' = \Psi'^\dagger K \Psi'$.

1. Insert the definitions: $X' = \sum_{A,C} \sum_{D,E} M^*_{AD} \Psi_D\, K_{AC}\, M_{CE} \Psi^\dagger_E = \sum_{D,E} \Psi_D\, K'_{DE}\, \Psi^\dagger_E$ with $K' = M^\dagger K M$ (collect the numbers: $\sum_{A,C} M^*_{AD} K_{AC} M_{CE} = (M^\dagger K M)_{DE}$).

2. Exchange the two operators with the canonical rule, $\Psi_D \Psi^\dagger_E = -\Psi^\dagger_E \Psi_D + B_{DE}$: $X' = -\sum_{D,E} \Psi^\dagger_E K'_{DE} \Psi_D + \sum_{D,E} K'_{DE} B_{DE}$.

3. Rename $D \leftrightarrow E$ in the first sum, and write the second as a trace ($\sum_{D,E} K'_{DE} (B^T)_{ED} = \mathrm{tr}(K'B^T)$):

$$X' = \Psi^\dagger(-K'^T)\Psi + c, \qquad c = \mathrm{tr}(K'B^T).$$

So the conjugated bilinear is the bilinear with the matrix $-(M^\dagger K M)^T$ plus the number c (times the identity operator). The matrix $-(M^\dagger K M)^T$ is exactly the rule $\epsilon(M^\dagger K M)^T$ of Section 5.29 with $\epsilon = -1$, the rule of classical anticommuting components. When $-(M^\dagger K M)^T = sK$ with a sign s, the result is $X' = sX + c$.

The constant c. For the scalar and the currents K' is $\pm C$ or $\pm iC\gamma^a$, and $B^T = -B = iC\gamma^{(x4)}$. Then $K'B^T$ is a number times $C\,C\gamma^{(x4)} = \gamma^{(x4)}$ or times $C\gamma^a C\gamma^{(x4)} = -(\gamma^a)^T\gamma^{(x4)} = -\eta_{aa}\gamma^a\gamma^{(x4)}$ (by (C3), (C5) and the symmetry pattern). By Rule 5 of Section 5.3 the trace of a product of different gammas is zero, so $c = 0$, except when $\gamma^a\gamma^{(x4)}$ is not a product of different gammas, that is for $a = x4$: the charge density, whose matrix $-iC\gamma^{(x4)}$ is B itself. For $M = 1$, $K' = B$ and $c = \mathrm{tr}(BB^T) = -\mathrm{tr}(BB) = -\mathrm{tr}\,1 = -16$; for $M = \Gamma$, $K' = \Gamma B\Gamma = -B$ and $c = +16$.

Normal ordering removes c and nothing else. For an operator X built from two field operators, **normal ordering** is the subtraction of its vacuum value, $:X: = X - \langle 0|X|0\rangle$ (for products of b, b^*, d, d^* this is the same as moving every creation operator to the left of every annihilation operator, with a sign for each exchange). From $X' = sX + c$, the vacuum value is $\langle 0|X'|0\rangle = s\langle 0|X|0\rangle + c$, and

$$:X': = X' - \langle 0|X'|0\rangle = sX + c - s\langle 0|X|0\rangle - c = s\ :X: .$$

The constant cancels and the sign stays. **After normal ordering the quantised bilinears change with the signs of the classical anticommuting components.** The argument uses only the canonical rule and the fact that normal ordering subtracts a number, so it does not depend on the momentum of the example or on the choice of the vacuum. For the allowed map $M = \Gamma$ the anticommuting row of Section 5.29 gives $(S, J) \to (-S, -J)$: every current is reversed, so the normal-ordered charge of every quantum changes sign (particles $+1 \to -1$, antiparticles $-1 \to +1$), and the scalar is reversed, so the mass term mS becomes $(-m)S$: **the conjugation of the quantised field exchanges particles and antiparticles and reverses the mass**, as the Revision record states.

What the record says. The detail text of the lead check `bilinears_under_charge_conjugation` states the same result: normal ordering adds no sign, because it subtracts the vacuum value, a number, so that $X' = sX + c$ gives $:X': = s\ :X:$, and the quantised bilinears keep the signs of the classical anticommuting components. The record makes no Fock-space computation; Notebook 05e makes one and confirms the derivation above. For $M = 1$ the normal-ordered result is therefore $(S, J) \to (-S, +J)$, the record's measured anticommuting row. An earlier version of that detail text said instead, in parentheses, that normal ordering supplies one more sign for each bilinear, which would have given $(S, J) \to (S, -J)$ for $\mathcal{C}_+$; the derivation above and Notebook 05e contradicted it, and the record was corrected on 2026-10-08. The contradiction is resolved: the record, this derivation and the Fock-space computation agree.

statement	status	where it is verified
the canonical relations of fermion operators, 2 and 16 modes	COMPUTED exactly (2 modes) and on a random state (16 modes)	Notebook 05e, In [4] and In [6] (its own computation)

statement	status	where it is verified
$\{\Psi_A, \chi_C\} = \delta_{AC}$, $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$ in the positive realisation	PROVED; COMPUTED on 65536 states	`Revision/theory/reports/wolfram-field-theory.json`, check `Fock_space_good_sector_example`; Notebook 05e, In [8]
the canonical conjugate is not a Hilbert adjoint ($\{X, X^\dagger\} = -1$)	PROVED; COMPUTED	the same report, check `no_positive_inner_product`; Notebook 05e, In [10]
vacuum energy $-8E = -40$, energies $+5$, charges ± 1	COMPUTED (to 10^{-12})	the same report, check `Fock_space_good_sector_example`; Notebook 05e, In [12]
$MB^TM^\dagger = B$ for $M = \Gamma$, $= -B$ for $M = 1$	PROVED; COMPUTED on the Fock space	`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, check `quantum_charge_conjugation_unitary_type`; Notebook 05e, In [14]
$X' = sX + c$ with the anticommuting signs; $c = \mp 16$ for the charge density, 0 otherwise	PROVED; COMPUTED on the Fock space	Notebook 05e, In [16] and In [17]; the signs equal the anticommuting rows of the lead check `bilinears_under_charge_conjugation`
$:X':= s\ :X:;\ \Psi \to \Gamma\Psi^{\dagger T}$ reverses the charge of every quantum	PROVED; COMPUTED	Notebook 05e, In [18] and In [19] (its own computation); the detail text of the lead check `bilinears_under_charge_conjugation` states the first part (normal ordering adds no sign)

5.35 Example: Notebook 05e computes the conjugation of the quantised field

Notebook 05e builds fermion operators from zero, first for two modes as 4×4 matrices and then for sixteen modes on the Fock space of 65536 patterns, where a state is stored as a list of its nonzero amplitudes. It realises the quantised field of the record's good-sector example ($m = 3$, momentum 4 along $x1$, $E = 5$), checks the canonical rule, shows why the canonical conjugate cannot be a Hilbert adjoint, and reproduces the vacuum energy -40, the energies $+5$ and the charges ± 1 of the 16 quanta. Then it applies the two conjugations $M = 1$ and $M = \Gamma$ to the operators, measures the anticommutators, computes all nine conjugated bilinears as operators, finds the sign and the constant of $X' = sX + c$, and checks that normal ordering removes the constant and keeps the sign. It reads `Revision/algebra/gammas.json`, `Revision/theory/field-theory.json`, `Revision/theory/reports/wolfram-field-theory.json` and `Revision/lead_checks/reports/charge-conjugation-and-u1.json`. It draws eight figures and ends with the line ALL 18 CHECKS PASSED (notebook 05e).

5.36 How to run Notebook 05e

Step 1. What this notebook does and what it needs.

Notebook 05e (The quantised field: reordering operators, normal ordering and the conjugated bilinears) is the file `Revision/textbook/notebooks/05e_quantum_bilinears.ipynb` of the repository Dirac_claude. It builds the fermion Fock space of 16 modes (65536 states) of the good-sector example of the Revision record, realises the quantised field with the Hilbert adjoint chi and the canonical conjugate Psi^dagger = chi B, checks the rules {Psi_A, chi_C} = delta_AC and {Psi_A, Psi^dagger_C} = B_AC, shows why Psi^dagger cannot be the Hilbert adjoint, reproduces the recorded vacuum energy, the energies and charges of the 16 quanta and the expectation-value rule, applies the two conjugations Psi to M Psi^(dagger T) with M = 1 and M = Gamma to the operators, and computes exactly how the scalar S and the eight currents J^a change as operators: by the sign of the classical anticommuting components plus a constant, which normal ordering removes. Eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
```

```
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 05e_quantum_bilinears.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a

number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05e_quantum_bilinears.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 05e_quantum_bilinears.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/05e.captions.json`
- `Revision/textbook/figures/05e_1_two_modes.png`
- `Revision/textbook/figures/05e_2_anticommutators.png`
- `Revision/textbook/figures/05e_3_why_krein.png`
- `Revision/textbook/figures/05e_4_quanta.png`
- `Revision/textbook/figures/05e_5_conjugated_rules.png`
- `Revision/textbook/figures/05e_6_vacuum_values.png`
- `Revision/textbook/figures/05e_7_sign_tables.png`
- `Revision/textbook/figures/05e_8_conjugated_charges.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the eight figure files of notebook 05e exist
ALL 18 CHECKS PASSED (notebook 05e)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/05e_quantum_bilinears.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 05e_quantum_bilinears.ipynb
python -m nbconvert --execute --inplace 05e_quantum_bilinears.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`, `Revision/theory` or `Revision/lead_checks`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

5.37 Notebook 05e: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/05e_quantum_bilinears.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field dirac16complex is **quantised**: its 16 components become *operators*,
and the charge-conjugation maps of the previous notebooks of this chapter act on
operators. Exchanging two operators is not free: it costs a sign and leaves a
number behind (their anticommutator). This notebook computes, on an explicit
computer model of the quantum states, what the two charge-conjugation maps do to
the scalar $S = \Psi^\dagger C\Psi$ and to the eight currents $J^a =
\Psi^\dagger(-iC\gamma^a)\Psi$ of the quantised field. It

1. builds the operators of fermions from zero (two modes, then sixteen modes with
   $2^{16} = 65536$ states);
2. realises the quantised field of the Revision record for one momentum without
   extra-time part (the record's example $m = 3$, momentum 4 along $x1$, energy
   $E = 5$), with the Hilbert adjoint $\chi$ and the canonical conjugate
   $\Psi^\dagger = \chi B$, and checks $\{\Psi_A, \chi_C\} = \delta_{AC}$ and
   $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$;
3. shows why $\Psi^\dagger$ cannot be the Hilbert adjoint (an indefinite, Krein,
   inner product is needed), as the record proves;
4. reproduces the recorded vacuum energy $-8E = -40$, the energies $+5$ and the
   charges $\pm 1$ of the 16 quanta, and the expectation-value rule;
5. applies the two conjugations $\Psi \to M\Psi^{\dagger T}$ with $M = 1$ (the
   type of $\mathcal{C}_+$) and $M = \Gamma$ (the type of $\mathcal{C}_-$) to the
   operators: of the two, only $M = \Gamma$ keeps the canonical rule;
6. computes every conjugated bilinear as an operator: it is the original bilinear
   times a sign, plus a constant; the sign is the one of the classical
   *anticommuting* components; **normal ordering** removes the constant and
   nothing else.

Eight teaching plots.
```

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 05e (The quantised field: reordering operators, normal ordering and the
conjugated bilinears) is the file
‘Revision/textbook/notebooks/05e_quantum_bilinears.ipynb‘ of the repository Dirac_claude.
It builds the fermion Fock space of 16 modes (65536 states) of the good-sector example of
the Revision record, realises the quantised field with the Hilbert adjoint chi and the
canonical conjugate Psi^dagger = chi B, checks the rules {Psi_A, chi_C} = delta_AC and
{Psi_A, Psi^dagger_C} = B_AC, shows why Psi^dagger cannot be the Hilbert adjoint,
reproduces the recorded vacuum energy, the energies and charges of the 16 quanta and the
expectation-value rule, applies the two conjugations Psi to M Psi^(dagger T) with M = 1
and M = Gamma to the operators, and computes exactly how the scalar S and the eight
currents J^a change as operators: by the sign of the classical anticommuting components
plus a constant, which normal ordering removes. Eight teaching plots. It needs a computer
with Windows 11, macOS or Linux, an internet connection for the installation, the program
Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages
run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv

Then close the terminal and open a NEW one (a terminal opened before the installation
does not know the new programs), and check the version of Python; it must print 3.12 or a
```

higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
```

```
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 05e_quantum_bilinears.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut

Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 05e_quantum_bilinears.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 05e_quantum_bilinears.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/05e.captions.json‘
- ‘Revision/textbook/figures/05e_1_two_modes.png‘
- ‘Revision/textbook/figures/05e_2_anticommutators.png‘
- ‘Revision/textbook/figures/05e_3_why_krein.png‘
- ‘Revision/textbook/figures/05e_4_quanta.png‘
- ‘Revision/textbook/figures/05e_5_conjugated_rules.png‘
- ‘Revision/textbook/figures/05e_6_vacuum_values.png‘
- ‘Revision/textbook/figures/05e_7_sign_tables.png‘
- ‘Revision/textbook/figures/05e_8_conjugated_charges.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the eight figure files of notebook 05e exist
ALL 18 CHECKS PASSED (notebook 05e)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started

```
  without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
  again. If the error remains, another Python installation has registered its own kernel
  called python3; with the environment active, run the following command and start
  JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from
  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/05e_quantum_bilinears.ipynb‘ inside the folder
  Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 05e_quantum_bilinears.ipynb
      python -m nbconvert --execute --inplace 05e_quantum_bilinears.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘, ‘Revision/theory‘
  or ‘Revision/lead_checks‘: the notebook was opened outside the repository, or the
  repository is incomplete; clone the repository again and open the notebook from its
  folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 05e (the complete instructions)
#
```

```
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 05e (The quantised field: reordering operators, normal ordering and the
# conjugated bilinears) is the file
# Revision/textbook/notebooks/05e_quantum_bilinears.ipynb of the repository Dirac_claude.
# It builds the fermion Fock space of 16 modes (65536 states) of the good-sector example
# of the Revision record, realises the quantised field with the Hilbert adjoint chi and
# the canonical conjugate Psi^dagger = chi B, checks the rules {Psi_A, chi_C} = delta_AC
# and {Psi_A, Psi^dagger_C} = B_AC, shows why Psi^dagger cannot be the Hilbert adjoint,
# reproduces the recorded vacuum energy, the energies and charges of the 16 quanta and
# the expectation-value rule, applies the two conjugations Psi to M Psi^(dagger T) with M
# = 1 and M = Gamma to the operators, and computes exactly how the scalar S and the eight
# currents J^a change as operators: by the sign of the classical anticommuting components
# plus a constant, which normal ordering removes. Eight teaching plots. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
```

```
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
```

```
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 05e_quantum_bilinears.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 05e_quantum_bilinears.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
```

```
# 05e_quantum_bilinears.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/05e.captions.json
# - Revision/textbook/figures/05e_1_two_modes.png
# - Revision/textbook/figures/05e_2_anticommutators.png
# - Revision/textbook/figures/05e_3_why_krein.png
# - Revision/textbook/figures/05e_4_quanta.png
# - Revision/textbook/figures/05e_5_conjugated_rules.png
# - Revision/textbook/figures/05e_6_vacuum_values.png
# - Revision/textbook/figures/05e_7_sign_tables.png
# - Revision/textbook/figures/05e_8_conjugated_charges.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the eight figure files of notebook 05e exist
#     ALL 18 CHECKS PASSED (notebook 05e)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/05e_quantum_bilinears.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
```

```
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 05e_quantum_bilinears.ipynb
#     python -m nbconvert --execute --inplace 05e_quantum_bilinears.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra, Revision/theory or
#   Revision/lead_checks: the notebook was opened outside the repository, or the
#   repository is incomplete; clone the repository again and open the notebook from its
#   folder Revision/textbook/notebooks.

## 3. The words used in this notebook

- **Operator**: a rule that turns a state into another state, here a big matrix
  that acts on columns of numbers. Operators are multiplied by doing one after the
  other; the order matters.
- **Anticommutator** of two operators: $\{X, Y\} = XY + YX$.
- **Mode, occupation, pattern**: a fermion *mode* is a place that holds zero or one
  particle. With 16 modes a basis state is a *pattern* of 16 occupations (0 or 1);
  the computer stores it as a whole number $n$ whose binary digit $p$ is the
```

```
  occupation of mode $p$ ($p = 0, \dots, 15$). There are $2^{16} = 65536$ patterns.
- **Fock space**: all combinations of the 65536 basis states. A **state** is stored
  as a dictionary `{pattern: amplitude}` that lists only the nonzero amplitudes.
- **Vacuum** $|0\rangle$: the pattern with no mode occupied (the whole number 0).
- **Annihilation and creation operators** $f_p$, $f_p^*$: $f_p$ empties mode $p$
  (and gives zero if it is empty), $f_p^*$ fills it (zero if it is full), each with
  a sign $(-1)^{(\text{number of occupied modes below } p)}$. They obey the
  **canonical anticommutation relations** $\{f_p, f_q^*\} = \delta_{pq}$,
  $\{f_p, f_q\} = 0$, $\{f_p^*, f_q^*\} = 0$ ($\delta_{pq}$ is 1 for $p = q$ and 0
  otherwise). In particular $f_pf_p = 0$: no mode holds two fermions.
- **Hilbert adjoint** $X^*$ of an operator: the conjugate transpose of its matrix
  (with the ordinary, positive inner product of the Fock space).
- **Particle and antiparticle operators**: $b_s = f_{s-1}$ for $s = 1, \dots, 8$
  (modes 0 to 7) and $d_s = f_{s+7}$ (modes 8 to 15).
- **Field operators**: $\Psi_A = \sum_s \big((u_s)_A b_s + (v_s)_A d_s^*\big)$ for
  $A = 1, \dots, 16$, with $\chi_A$ its Hilbert adjoint and the **canonical
  conjugate** $\Psi^\dagger_A = \sum_C \chi_C B_{CA}$.
- **Momentum**: a field of one momentum $k$ along $x1$ has the form
  $\psi\,e^{ik\,x1}$, a column $\psi$ times the number $e^{ik\,x1} = \cos(k\,x1) +
  i\sin(k\,x1)$; $k$ is a real number. The **good sector**: momenta without a part
  along the extra times $x5$, $x6$, $x7$ (the field does not depend on them).
- **Energy**: a column that depends on the time as $e^{-iE\,x4}$ ($E$ real) has
  the energy $E$.
- **Mode Hamiltonian** $h$: the $16 \times 16$ matrix with $E\,u = h\,u$ for the
  field $u\,e^{i(k\,x1 - E\,x4)}$ of one momentum; its eigenvalues are the energies
  of the fields of that momentum (section 8 derives it). The **energy density** is
  the energy per unit volume.
- **Orthonormal** columns: each has length 1 ($u^\dagger u = 1$) and every two are
  perpendicular ($u^\dagger w = 0$).
- **Delta function** $\delta^7(x - y)$: an idealised object that is zero whenever
  the point $x$ differs from $y$ and whose integral over the seven coordinates
  other than the time is 1.
- **Krein space**: a space with an *indefinite* inner product (some vectors have a
  negative norm).
- **Bilinear operator**: $\Psi^\dagger K\Psi = \sum_{A,C}\Psi^\dagger_A K_{AC}
  \Psi_C$ for a fixed $16 \times 16$ matrix $K$.
- **Vacuum value** $\langle 0|X|0\rangle$ of an operator $X$ and **normal ordering**
  $:\!X\!: = X - \langle 0|X|0\rangle$ (for an operator built from two field
  operators; for products of $b$, $b^*$, $d$, $d^*$ this is the same as moving every
  creation operator to the left of every annihilation operator, with a sign $-1$
  for each exchange).
- **Expectation value** $\langle q|X|q\rangle$ in a normalised state $q$.
```

Text cell:

```
## 4. The physical and mathematical situation

**The canonical rule.** The Revision record quantises dirac16complex with the
canonical anticommutator $\{\Psi_A(x), \Psi^\dagger_C(y)\} = B_{AC}\,
\delta^7(x - y)/\cos z$ on a slice $x4 = \text{const}$, $B = -iC\gamma^{(x4)}$. For
the operators of ONE momentum (the record's exact Fock-space example) the delta
function and the factor $1/\cos z$ are absent and the rule reads
$\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$.
```

Why $\Psi^\dagger$ is not the Hilbert adjoint. Every diagonal entry of B is zero. If $\Psi^\dagger_A$ were the Hilbert adjoint Ψ_A^*, then for every state ϕ: $\langle\phi|\{\Psi_A, \Psi_A^*\}|\phi\rangle = |\Psi_A^*\phi|^2 + |\Psi_A\phi|^2$ (a sum of squared lengths), and the rule would make it $B_{AA} = 0$; a sum of two squared lengths is zero only when both are zero, so $\Psi_A\phi = 0$ for every ϕ, and Ψ_A would be the zero operator. But row A of B has a nonzero entry B_{AC}, and the rule demands $\{\Psi_A, \Psi^\dagger_C\} = B_{AC} \neq 0$, while the anticommutator of the zero operator with anything is zero: a contradiction. The record makes the same argument with a vector u of the eigenspace $B u = -u$: $X = \sum_A u_A^*\Psi_A$ has $\{X, X^\dagger\} = u^\dagger Bu = -1 < 0$. The record's way out: $\Psi^\dagger = \chi B$, where χ is the Hilbert adjoint, on a positive Fock space. Line by line: $\{\Psi_A, \chi_C\} = \sum_s (u_s)_A(u_s)^*_C + \sum_s (v_s)_A(v_s)^*_C = (WW^\dagger)_{AC} = \delta_{AC}$ (the columns u_s, v_s of W are orthonormal and complete), and then $\{\Psi_A, \Psi^\dagger_C\} = \sum_D\{\Psi_A, \chi_D\}B_{DC} = B_{AC}$.

The conjugation of the quantised field. For a real matrix M put $\Psi'_A = \sum_C M_{AC}\Psi^\dagger_C$ (the operator form of $M\Psi^*$, written $M\Psi^{\dagger T}$) and, taking the conjugate of both sides (which reverses the order and conjugates numbers), $\Psi'^\dagger_A = \sum_C M_{AC}^*\Psi_C$. Then $\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{D,E}M_{AD}M^*_{CE}\{\Psi^\dagger_D, \Psi_E\} = \sum_{D,E}M_{AD}B_{ED}M^*_{CE} = (MB^TM^\dagger)_{AC}$. The rule is kept exactly when $MB^TM^\dagger = B$.

The conjugated bilinear, line by line. Let $X = \Psi^\dagger K\Psi$ and $X' = \Psi'^\dagger K\Psi'$.

1. Insert the definitions: $X' = \sum_{A,C}\sum_{D,E}M^*_{AD}\Psi_D K_{AC}M_{CE} \Psi^\dagger_E = \sum_{D,E}\Psi_D\,K'_{DE}\,\Psi^\dagger_E$ with $K' = M^\dagger KM$.
2. Exchange the two operators with the canonical rule, $\Psi_D\Psi^\dagger_E = -\Psi^\dagger_E\Psi_D + B_{DE}$: $X' = -\sum_{D,E}\Psi^\dagger_E K'_{DE}\Psi_D + \sum_{D,E}K'_{DE}B_{DE}$.
3. Rename $D \leftrightarrow E$ in the first sum and write the second as a trace: $$X' = \Psi^\dagger\big(-K'^T\big)\Psi + c,\qquad c = \mathrm{tr}(K'B^T) .$$

So X' is the bilinear with the matrix $-(M^\dagger KM)^T$, plus the number c (times the identity operator). The matrix $-(M^\dagger KM)^T$ is exactly the rule for classical **anticommuting** components (the exchange of two components costs the sign $\epsilon = -1$); for commuting components the rule is $+(M^\dagger KM)^T$. When $-(M^\dagger KM)^T = sK$ with a sign s, the result is $X' = sX + c$.

Normal ordering. Subtracting vacuum values: $:\!X'\!: = X' - \langle 0|X'|0\rangle = sX + c - s\langle 0|X|0\rangle - c = s\,:\!X\!:$. The constant c cancels and the sign s stays: after normal ordering the quantised bilinears change with the signs of the classical anticommuting components. The argument uses only that normal ordering subtracts a number; it holds for every choice of vacuum.

The notebook checks every one of these statements on the Fock space.

Text cell:

5. The gammas, C, Gamma, B and the Revision records

The next cell reads the gammas (exact whole numbers) from
‘Revision/algebra/gammas.json‘ and builds $C = \gamma^{(x0)}\gamma^{(x1)}
\gamma^{(x2)}\gamma^{(x3)}$, $\Gamma = \gamma^{(x0)}\gamma^{(x1)}\cdots
\gamma^{(x7)}$ and $B = -iC\gamma^{(x4)}$. It reads the two reports whose checks
this notebook repeats and defines the helpers ‘recorded(key, name)‘ (true when
the report ‘key‘, "lead" or "wolfram", holds the check ‘name‘ with the verdict
pass), ‘detail(key, name)‘ (its detail text), ‘record_of(key, name)‘ (the text
printed after "reproduces") and ‘check_reproduces(condition, name, record)‘, the
helper ‘check‘ for a check that reproduces a Revision record: it lets ‘check‘ print
the PASS line and the line "reproduces ..." into a text buffer
(‘contextlib.redirect_stdout‘) and sends both lines with one ‘sys.stdout.write‘,
because Jupyter delivers printed text in pieces and one piece keeps the two lines
together for the tools that read the notebook. The first check confirms the
facts about B used in section 4.

In [2]:

```

## 6. Fermion operators from zero: two modes

With two modes there are four patterns: $n = 0$ (both empty, written $|00\rangle$),
$n = 1$ (mode 0 full, $|10\rangle$), $n = 2$ (mode 1 full, $|01\rangle$) and
$n = 3$ (both full, $|11\rangle$). The next cell writes $f_0$, $f_0^*$, $f_1$,
$f_1^*$ as $4 \times 4$ matrices: column $n$ holds the image of the pattern $n$.
The sign rule: acting on mode $p$ costs $-1$ for every occupied mode below $p$. So
$f_1|11\rangle = -|10\rangle$ (mode 0 below is full) while $f_0|11\rangle =
|01\rangle$. The cell checks the canonical relations and $f_pf_p = 0$, and that
$f_p^*$ is the transpose of $f_p$ (the matrices are real, so this is the Hilbert
adjoint). Without the sign, $f_0$ and $f_1$ would *commute*; with it they
anticommute.
```

In [4]:

```
def two_mode_matrix(p, filling):
    """The 4 x 4 matrix of f_p (filling=False) or f_p^* (filling=True), 2 modes."""
    matrix = np.zeros((4, 4), dtype=np.int64)

## 7. Sixteen modes: the Fock space of 65536 states

The next cell defines the operators for 16 modes. A state is a dictionary
‘{pattern: amplitude}‘; ‘annihilate(p, state)‘ is $f_p$ and ‘create(p, state)‘ is
$f_p^*$, with the sign rule of section 6; ‘combine(terms)‘ adds up states with
coefficients; ‘inner(left, right)‘ is the ordinary (positive) inner product
$\langle\text{left}|\text{right}\rangle = \sum_n \text{left}_n^*\,\text{right}_n$;
‘largest(state)‘ is the largest size of an amplitude. It then checks the canonical
```

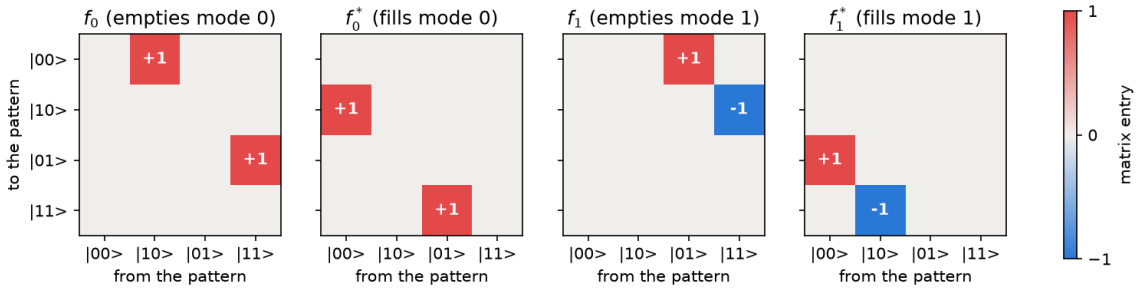

Figure 174: The annihilation and creation operators of two fermion modes as 4 by 4 matrices: column the pattern acted on, row the resulting pattern (00: both modes empty, 10: mode 0 full, 01: mode 1 full, 11: both full); red +1, blue −1, grey 0. Each operator moves one pattern to another; f_1 acting on the full pattern 11 gives −1 times the pattern 10, because mode 0 below it is occupied. This sign makes operators of different modes anticommute. (Notebook 05e, figure 1.)

```
relations $\{f_p, f_q^*\} = \delta_{pq}$ and $\{f_p, f_q\} = 0$ for all
$16 \times 16$ pairs on a random state: a dictionary with six random patterns and
random complex amplitudes, from the random-number generator with the fixed seed
12345 (so every run uses the same numbers).

## 8. The quantised field of one good-sector momentum

The Revision record's exact Fock-space example has the mass $m = 3$ and the
momentum 4 along $x1$, so $E = \sqrt{3^2 + 4^2} = 5$; it has no extra-time
momentum (the *good sector*). It treats the metric near one point as flat
(constant gammas, no spin-connection term). Inserting $\Psi = u\,e^{i(k\,x1 -
E\,x4)}$ into $\gamma^{(x4)}\partial_{x4}\Psi + \gamma^{(x1)}\partial_{x1}\Psi =
m\Psi$ gives $-iE\gamma^{(x4)}u + ik\gamma^{(x1)}u = mu$; multiplying by
$-i\gamma^{(x4)}$ (with $\gamma^{(x4)}\gamma^{(x4)} = -1$) gives $Eu = hu$ with
the mode Hamiltonian $h = -im\gamma^{(x4)} - k\gamma^{(x4)}\gamma^{(x1)}$, here
with $k = 4$. Both matrices $-i\gamma^{(x4)}$ and $\gamma^{(x4)}\gamma^{(x1)}$ are
Hermitian ($\gamma^{(x4)}$ is real antisymmetric; $\gamma^{(x4)}\gamma^{(x1)}$ is
```

```
real symmetric), they anticommute,
and $(-i\gamma^{(x4)})^2 = (\gamma^{(x4)}\gamma^{(x1)})^2 = 1$, so $hh = (9 + 16)1
= 25\cdot 1$. The next cell builds $h$ and checks this, and finds orthonormal
eigenvectors $u_1, \dots, u_8$ ($hu_s = 5u_s$) and $v_1, \dots, v_8$
($hv_s = -5v_s$) as orthonormal columns of the projectors $\frac12(1 \pm h/E)$ (the
Gram-Schmidt procedure: subtract from each column its parts along the columns
already kept, divide by its length, keep it if the length is not zero). The 16
columns form the matrix $W$, with $W^\dagger W = WW^\dagger = 1$.
```

## 9. Why the canonical conjugate is not the Hilbert adjoint
```

```
The record's check 'no_positive_inner_product' uses the vector $u$ with
$u_7 = -i/\sqrt2$, $u_{16} = 1/\sqrt2$ and all other entries 0, which obeys
$Bu = -u$. The next cell checks $Bu = -u$ and $u^\dagger Bu = -1$, forms
$X = \sum_A u_A^*\Psi_A$ with its Hilbert adjoint $X^* = \sum_A u_A\chi_A$ and its
canonical conjugate $X^\dagger = \sum_A u_A\Psi^\dagger_A$, and measures
$\{X, X^*\} = +1$ (positive, as for every operator and its Hilbert adjoint) and
$\{X, X^\dagger\} = -1$ (negative): the canonical conjugate cannot be the adjoint of
a positive inner product. The cell also computes the 16 eigenvalues of $B$ (eight
$+1$, eight $-1$).
```

In [10]:

```

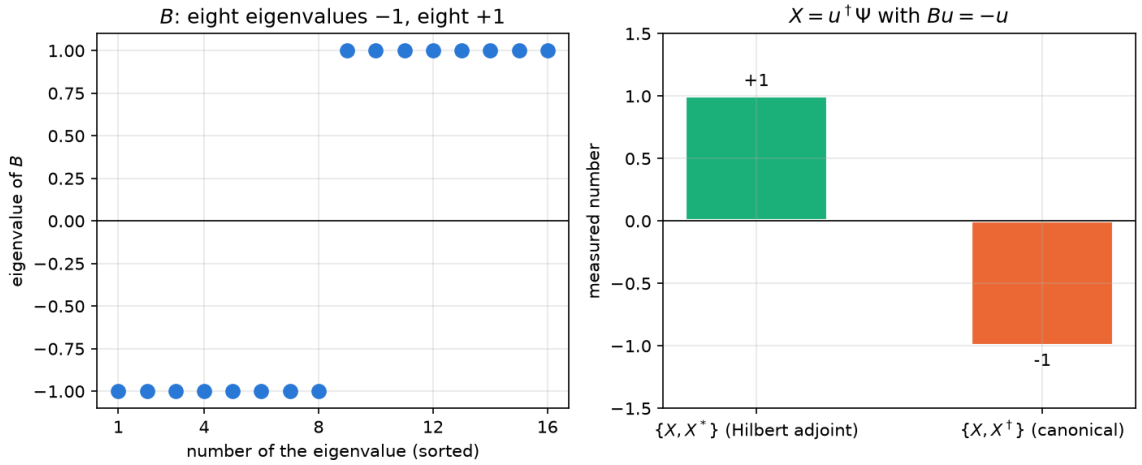

Figure 176: Why the quantised field needs an indefinite (Krein) inner product. Left: the 16 eigenvalues of B, sorted (horizontal axis their number, vertical axis their value): eight are -1 and eight are $+1$. Right: for the operator $X = u^\dagger\Psi$ built from an eigenvector u of B with eigenvalue -1, the anticommutator with its Hilbert adjoint is $+1$ (green), as it must be for every operator in a space with a positive inner product, while the canonical rule gives $u^\dagger Bu = -1$ (orange). (Notebook 05e, figure 3.)

## 10. The vacuum, the 16 quanta and the expectation-value rule

A **bilinear** $\sum_{A,C}L_A K_{AC}R_C$ of two operators with rows $L_A$, $R_C$
is $\sum_{i,j}Q_{ij}O_iO_j$ with the $32 \times 32$ matrix $Q = L^TKR$. The next
cell defines ‘bilinear(L, K, R, state)‘, ‘vacuum_value‘ and ‘normal_ordered_value‘
(the value in a state minus the vacuum value), and computes, as the record does:

- the energy $\chi h\Psi$: its vacuum value must be $-8E = -40$ (the filled sea),
  and after normal ordering each of the 16 quanta $b_s^*|0\rangle$, $d_s^*|0\rangle$
  must have the energy $+5$;
- the charge $J^{(x4)} = \Psi^\dagger B\Psi = \chi BB\Psi = \chi\Psi$: vacuum value 8;
  after normal ordering $+1$ for the 8 particles and $-1$ for the 8 antiparticles;
- the expectation-value rule of the record: $\langle q|:\!\Psi^\dagger M\Psi\!:|q
  \rangle = u_s^\dagger BMu_s$ for the particle $q = b_s^*|0\rangle$ and
  $-v_s^\dagger BMv_s$ for the antiparticle $q = d_s^*|0\rangle$, for the record's
  matrices $M = C$, $-iC\gamma^{(x4)}$ and $-iC\gamma^{(x1)}$.
```

## 11. The two conjugations of the quantised field
```

```
The next cell builds the conjugated operators of section 4 for $M = 1$ and
$M = \Gamma$: the rows of $\Psi'_A = \sum_C M_{AC}\Psi^\dagger_C$ are `M @ PSI_DAG`
and those of $\Psi'^\dagger_A = \sum_C M^*_{AC}\Psi_C$ are `M.conj() @ PSI`. It
measures $\{\Psi'_A, \Psi'^\dagger_C\}$ on the random state and compares with
$MB^TM^\dagger$, which the Revision record computed: $-B$ for $M = 1$ (the rule is
broken) and $+B$ for $M = \Gamma$ (the rule is kept).
```

In [14]:

```
MAPS = {"M = 1": I16, "M = Gamma": Gamma}  # the two conjugation matrices

## 12. The conjugated bilinears: a sign and a constant

The next cell computes, for the scalar ($K = C$) and the eight currents
($K = -iC\gamma^a$) and for both maps, the conjugated operator $X' =
\Psi'^\dagger K\Psi'$ and the original $X = \Psi^\dagger K\Psi$, both applied to
the random state, and finds the sign $s$ and the number $c$ with $X' = sX + c$.
Section 4 predicts $c = \mathrm{tr}(K'B^T)$ with $K' = M^\dagger KM$, and $s$ from
$-(M^\dagger KM)^T = sK$. The cell compares the measured signs with the table that
the Revision record measured for classical *anticommuting* components (its keys
‘plus,eps=-1‘ and ‘minus,eps=-1‘, stored in the detail text after the word
measured).

vacuum values <0|X|0>: S -4.80, J^(x0) +0.00, J^(x1) -6.40, J^(x2) +0.00, J^(x3) +0.00,
    J^(x4) +8.00, J^(x5) +0.00, J^(x6) +0.00, J^(x7) +0.00
PASS <0|X'|0> = s <0|X|0> + c for all 9 bilinears and both maps
```

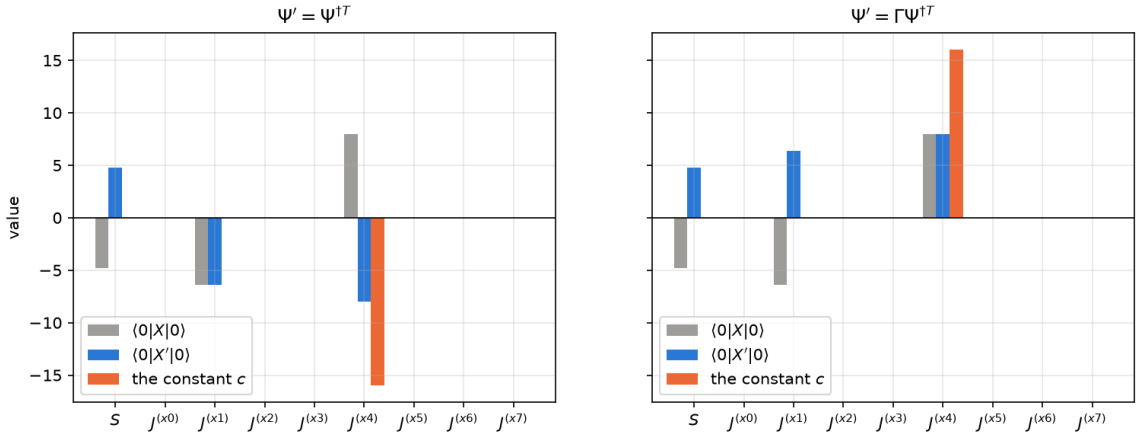

Figure 179: Vacuum values of the nine bilinears (horizontal axis: the scalar S and the currents J^a) before the conjugation (grey) and after it (blue), and the constant c of the identity $X' = sX + c$ (orange), for the conjugation with $M = 1$ (left) and $M = \Gamma$ (right); vertical axis the value (a pure number). The filled sea gives nonzero vacuum values; c vanishes except for the charge density $J^{(x4)}$, where it is -16 or $+16$. Normal ordering subtracts each operator's own vacuum value, which removes c. (Notebook 05e, figure 6.)

## 13. After normal ordering: the sign table of the quantised field

The next cell normal-orders both sides, $:\!X\!: = X - \langle 0|X|0\rangle$ and
$:\!X'\!: = X' - \langle 0|X'|0\rangle$, and checks $:\!X'\!: = s\,:\!X\!:$ on the
random state and on the 16 one-quantum states, for all bilinears and both maps.
It then computes, as the Revision record does, the classical tables:
$\epsilon(M^\dagger KM)^T$ compared with $K$, for commuting ($\epsilon = +1$) and
anticommuting ($\epsilon = -1$) components, and draws three tables: commuting,
anticommuting and the quantised field after normal ordering.
```

What the record says. The detail text of the record's check
‘bilinears_under_charge_conjugation‘ states that normal ordering adds no sign: it
subtracts the vacuum value, a number, so $X' = sX + c$ gives
$:\!X'\!: = s\,:\!X\!:$. The record makes no Fock-space computation; this cell
makes one. It confirms the statement: normal ordering removes only the constant
c, and the operator signs are exactly the measured signs of the anticommuting
rows. (Until 2026-10-08 that detail text said instead that normal ordering
supplies one more sign for each bilinear, which would give $(S, J) \to (S, -J)$
for $\mathcal{C}_+$; this computation contradicted it, and the record was
corrected.)

## 16. What this notebook showed

- PROVED (section 4, line by line) and COMPUTED (on the Fock space of 65536
  states): for the quantised field, the conjugated bilinear is
  $X' = \Psi^\dagger\big(-(M^\dagger KM)^T\big)\Psi + \mathrm{tr}(M^\dagger KMB^T)$:
  the rule of classical anticommuting components plus a constant.
- COMPUTED, reproducing the Revision record: the positive realisation
  $\Psi^\dagger = \chi B$ obeys $\{\Psi_A, \chi_C\} = \delta_{AC}$ and
  $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$; the canonical conjugate cannot be a Hilbert
  adjoint ($\{X, X^\dagger\} = -1$); the vacuum energy is $-8E = -40$, every quantum
  has the energy $+5$ after normal ordering, particles have the charge $+1$ and
  antiparticles $-1$; the expectation-value rule holds.
- COMPUTED, reproducing the lead record: $\Psi \to \Psi^{\dagger T}$ turns the
  canonical rule into $-B$, $\Psi \to \Gamma\Psi^{\dagger T}$ keeps it.
- COMPUTED: the operator signs equal the measured signs of the anticommuting rows
  of the record's table: $M = 1$ gives $(S, J) \to (-S, +J)$, $M = \Gamma$ gives
  $(S, J) \to (-S, -J)$. The constant $c$ vanishes except for the charge density
  ($\mp 16$), and normal ordering removes it: after normal ordering the quantised
  field has exactly the anticommuting signs. This agrees with the record's check
  `bilinears_under_charge_conjugation`, whose detail text states that normal
  ordering adds no sign.
- COMPUTED: of the two conjugations, the one that keeps the canonical rule,
  $\Psi \to \Gamma\Psi^{\dagger T}$ (among the multiples of 1 and of $\Gamma$ the
  only one, up to a phase factor), reverses the normal-ordered charge of every
  quantum.
- SCOPE: one momentum without extra-time part, at one point of space, with the
  metric treated as flat near that point; the vacuum is the Fock vacuum of that
  momentum. The sign argument of section 4 uses only the
  canonical rule and the subtraction of a number, so it does not depend on these
  choices.
```

5.38 Line-by-line walk-through of Notebook 05e

The notebook has 20 code cells. In [1] is the set-up cell of Section 5.10 with `NOTEBOOK_ID = "05e"`; its comments repeat the instructions of Section 5.36. Docstrings are left out of the quotations and long captions are shortened to ..., as before.

In [2], the gammas, C, Γ, B and the records.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer io.StringIO
import sys  # sys.stdout: the channel through which the notebook prints

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1
```

The modules and the gammas, as in Notebook 05c, In [2] (Section 5.33).

```
C = gamma["x0"] @ gamma["x1"] @ gamma["x2"] @ gamma["x3"]  # the charge matrix
Gamma = I16
for x in ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]:
    Gamma = Gamma @ gamma[x]  # the chirality: the product of all eight gammas
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4), entries 0, +i, -i
```

C, Γ and B; the loop multiplies the eight gammas in the author's order, starting from the identity.

```
REPORT_FILES = {"lead": "Revision/lead_checks/reports/charge-conjugation-and-u1.json",
                "wolfram": "Revision/theory/reports/wolfram-field-theory.json"}
VERDICTS = {}  # (report key, check name) -> (verdict in lower case, detail text)
for key, path in REPORT_FILES.items():
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in report_data["checks"]:
        VERDICTS[(key, entry["name"])] = (entry["verdict"].lower(), entry["detail"])
```

Two reports are read: the lead report of charge conjugation and the Wolfram report of the field theory, which holds the record's checks of the quantisation. Every check is stored under the pair (report key, check name), as in Notebook 05a (Section 5.10, In [3]).

```
def recorded(key, name):
    return VERDICTS[(key, name)][0] == "pass"

def detail(key, name):
    return VERDICTS[(key, name)][1]

def record_of(key, name):
    return f"{REPORT_FILES[key]}, check {name}"

def check_reproduces(condition, name, record):
    collected = io.StringIO()
```

```
    with contextlib.redirect_stdout(collected):  # print into the buffer
        check(condition, name, record=record)  # stops here if the check fails
    sys.stdout.write(collected.getvalue())  # the PASS and reproduces lines together
```

The four helpers of Notebook 05b (Section 5.17, In [2]): whether a report holds a check with the verdict pass, its detail text, the text printed after reproduces, and the check that prints its two lines in one piece.

```
say(f"{len(VERDICTS)} recorded checks were read from the two reports.")
check(np.array_equal(B.conj().T, B) and np.array_equal(B @ B, I16)
      and not np.any(np.diag(B)) and np.array_equal(B.T, -B),
      "B is Hermitian, B B = 1, B^T = -B and every diagonal entry of B is 0")
```

The printed line reports 96 checks: the 12 of the lead report and the 84 of the Wolfram report. The check confirms the facts about B that Section 5.34 uses: Hermitian, square 1, $B^T = -B$, and a zero diagonal (`np.diag(B)` is the list of the diagonal entries).

In [3], the rule of the record.

```
theory = json.loads(repository_file("Revision/theory/field-theory.json")
                    .read_text(encoding="utf-8"))
formula = next(f for f in theory["formulas"] if f["key"] == "quantisation")["wl"]
RULE = "{Psi_A(x), Psi^dagger_C(y)}_(x4 = y4) = B_AC delta^7(x - y)/Cos[z]"
POSITIVE = "positive representation chi = Psi^dagger B, {Psi_A, chi_C} = delta_AC"
say("the record states: " + RULE)
say("and: " + POSITIVE)
check(RULE in formula and POSITIVE in formula,
      "the formula quantisation of Revision/theory/field-theory.json states both rules")
```

The record `Revision/theory/field-theory.json` holds a list of formulas, each with a key and a text (`"wl"`, written in the notation of the Wolfram Language). `next(f for f in ... if ...)` takes the first formula whose key is `quantisation`. The two sentences that this notebook realises, the canonical rule and its positive representation with $\chi = \Psi^\dagger B$ (equivalently $\Psi^\dagger = \chi B$, because $BB = 1$), are printed, and the check confirms that the record's text contains both, character by character.

In [4], two modes as 4×4 matrices.

```
def two_mode_matrix(p, filling):
    matrix = np.zeros((4, 4), dtype=np.int64)
    for n in range(4):  # the pattern n: binary digit q = occupation of mode q
        full = (n >> p) & 1  # the occupation of mode p in the pattern n
        if full != filling:  # f_p needs a full mode, f_p^* an empty one
            below = bin(n & ((1 << p) - 1)).count("1")  # occupied modes below p
            matrix[n ^ (1 << p), n] = (-1) ** below  # ^ flips binary digit p
    return matrix
```

The computer stores a pattern of occupations as a whole number n whose **binary digits** are the occupations: digit q (counted from 0, from the right) is the occupation of mode q. So for two modes

$n = 0, 1, 2, 3$ are $|00\rangle$, $|10\rangle$, $|01\rangle$, $|11\rangle$. The operators on binary digits: shifting n to the right by p places and taking `& 1` (the last binary digit) gives the occupation of mode p; `1` shifted to the left by p places is the number with a single 1 in digit p, and subtracting 1 from it gives the number with ones in all digits below p; `n & (...)` keeps only those digits of n; `bin(...)` writes a number in binary digits, and `.count("1")` counts the occupied modes below p. The operator `^` (exclusive or) with that single-digit number flips digit p. For each pattern n on which the operator acts (`filling=False`: f_p, which needs a full mode; `filling=True`: f_p^*, which needs an empty one), column n of the matrix gets the entry $(-1)^{\text{below}}$ in the row of the new pattern. Columns of patterns on which the operator gives zero stay zero.

```
f2 = {p: two_mode_matrix(p, False) for p in (0, 1)}  # f_0, f_1
f2_star = {p: two_mode_matrix(p, True) for p in (0, 1)}  # f_0^*, f_1^*
Z4 = np.zeros((4, 4), dtype=np.int64)
relations_ok = all(
    np.array_equal(f2[p] @ f2_star[q] + f2_star[q] @ f2[p],
                   np.eye(4, dtype=np.int64) if p == q else Z4)
    and np.array_equal(f2[p] @ f2[q] + f2[q] @ f2[p], Z4)
    and np.array_equal(f2_star[p], f2[p].T)
    for p in (0, 1) for q in (0, 1))
```

The four matrices f_0, f_1, f_0^*, f_1^*, and for all four pairs (p, q) the canonical relations $\{f_p, f_q^*\} = \delta_{pq}1$ and $\{f_p, f_q\} = 0$, and that f_p^* is the transpose of f_p (the matrices are real, so the transpose is the Hilbert adjoint).

```
# column 3 of f_1 is the image of the pattern |11>; its entry in row 1 (|10>) is -1
say(f"f_1 applied to |11>: amplitudes on |00>, |10>, |01>, |11> = "
    f"{f2[1][:, 3].tolist()}")
check(relations_ok and all(not np.any(f2[p] @ f2[p]) for p in (0, 1)),
      "two modes: {f_p, f_q^*} = delta_pq, {f_p, f_q} = 0, f_p f_p = 0, "
      "f_p^* = f_p^T")
```

The printed line is column 3 of f_1, the image of $|11\rangle$: $[0, -1, 0, 0]$, that is $f_1|11\rangle = -|10\rangle$, the example of Section 5.34. The check adds $f_p f_p = 0$.

In [5], the picture of the two-mode operators.

```
from matplotlib.colors import LinearSegmentedColormap

SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
PATTERNS = ["|00>", "|10>", "|01>", "|11>"]  # the patterns n = 0, 1, 2, 3
fig, axes = plt.subplots(1, 4, figsize=(13.0, 3.5))
```

The colour map of the heat maps, the names of the four patterns and a row of four pictures.

```
for k, (ax, matrix, title) in enumerate(zip(
        axes, [f2[0], f2_star[0], f2[1], f2_star[1]],
        ["$f_0$ (empties mode 0)", "$f_0^*$ (fills mode 0)",
         "$f_1$ (empties mode 1)", "$f_1^*$ (fills mode 1)"])):
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
```

```
    for r in range(4):
        for c in range(4):
            if matrix[r, c]:
                ax.text(c, r, f"{matrix[r, c]:+d}", ha="center", va="center",
                        color="white", fontweight="bold")
```

For each of the four operators: its matrix as a heat map, and its nonzero entries written in their squares.

```
    ax.set_xticks(range(4), PATTERNS)

    ax.grid(False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "two_modes",
            ...)
```

The columns are labelled by the pattern acted on, the rows by the resulting pattern (only in the first picture). **What figure 05e.1 shows**: each operator moves one pattern to another, so each picture has two coloured squares; all are red (+1) except one blue square in f_1 (from $|11\rangle$ to $|10\rangle$) and one in f_1^* (from $|10\rangle$ to $|11\rangle$): the sign that makes operators of different modes anticommute.

In [6], sixteen modes.

```
def sign_below(n, p):
    return -1 if bin(n & ((1 << p) - 1)).count("1") % 2 else 1
```

`sign_below(n, p)` is (-1) to the power of the number of occupied modes below p in the pattern n: -1 when that number is odd (`% 2` is its remainder after division by 2).

```
def annihilate(p, state):
    result = {}
    for n, amplitude in state.items():
        if n >> p & 1:  # mode p is full in the pattern n
            new = n ^ (1 << p)  # the same pattern with mode p emptied
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result

def create(p, state):
    result = {}
    for n, amplitude in state.items():
        if not n >> p & 1:  # mode p is empty in the pattern n
            new = n | (1 << p)  # the same pattern with mode p filled
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result
```

With 16 modes there are 65536 patterns, too many for full matrices; a state is therefore stored as a dictionary `{pattern: amplitude}` that lists only the nonzero amplitudes. `annihilate(p, state)` is f_p: for every pattern in which mode p is full it adds the amplitude, times the sign, to the pattern with mode p emptied (`result.get(new, 0)` is the amplitude collected so far, 0 if none). `create(p, state)` is f_p^*: for every pattern in which mode p is empty it fills the mode (the operator `|`, the binary or, applied with the single-digit number sets digit p to 1).

```
def combine(terms):
    result = {}
    for coefficient, state in terms:
        for n, amplitude in state.items():
            result[n] = result.get(n, 0) + coefficient * amplitude
    return result

def inner(left, right):
    return sum(np.conj(a) * right.get(n, 0) for n, a in left.items())

def largest(state):
    return max((abs(a) for a in state.values()), default=0.0)
```

`combine` adds states with coefficients, $\sum c_j \,\text{state}_j$. `inner(left, right)` is the positive inner product $\sum_n \text{left}_n^* \,\text{right}_n$. `largest(state)` is the largest size of an amplitude, 0 for the empty dictionary (the zero state); it measures how far a state is from zero.

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed
RANDOM_STATE = {int(n): complex(rng.normal(), rng.normal())
                for n in rng.integers(0, 2 ** 16, size=6)}  # six random patterns
```

A random test state: six random patterns (whole numbers from 0 to 65535) with random complex amplitudes whose real and imaginary parts come from the normal distribution (the bell curve centred at 0). The fixed seed 12345 makes every run use the same numbers.

```
worst = 0.0  # the largest violation of a canonical relation
for p in range(16):
    for q in range(16):
        mixed = combine([(1, annihilate(p, create(q, RANDOM_STATE))),
                         (1, create(q, annihilate(p, RANDOM_STATE)))])
        expected = RANDOM_STATE if p == q else {}  # delta_pq times the state
        worst = max(worst, largest(combine([(1, mixed), (-1, expected)])))
        same = combine([(1, annihilate(p, annihilate(q, RANDOM_STATE))),
                        (1, annihilate(q, annihilate(p, RANDOM_STATE)))])
        worst = max(worst, largest(same))
say(f"patterns in the random state: {len(RANDOM_STATE)}; pairs tested: 2 x 256")
check(worst < 1e-12,
      "sixteen modes: {f_p, f_q^*} = delta_pq and {f_p, f_q} = 0 on a random state")
```

For all 16×16 pairs (p, q): $\{f_p, f_q^*\}$ applied to the random state minus δ_{pq} times the state, and $\{f_p, f_q\}$ applied to it; `worst` keeps the largest amplitude left over. The printed line reports 6 patterns and 2×256 tests; the check requires everything left over to be below 10^{-12}.

In [7], the mode Hamiltonian and its eigenvectors.

```
MASS, MOMENTUM = 3, 4  # the record's example: m = 3, momentum 4 along x1
E = float(np.sqrt(MASS ** 2 + MOMENTUM ** 2))  # the energy, 5
h = -1j * MASS * gamma["x4"] - MOMENTUM * (gamma["x4"] @ gamma["x1"])
```

The record's example: $m = 3$, momentum 4 along $x1$, $E = \sqrt{3^2 + 4^2} = 5$, and $h = -im\gamma^{(x4)} - 4\gamma^{(x4)}\gamma^{(x1)}$ (Section 5.34).

```
def orthonormal_columns(P):
    basis = []
    for column in P.T:
        v = column.astype(complex)
        for _ in range(2):  # a second pass removes rounding errors
            for e in basis:
                v = v - (e.conj() @ v) * e  # remove the part along e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:  # a new direction: keep it with length 1
            basis.append(v / length)
    return np.array(basis).T
```

The **Gram-Schmidt procedure**: it goes through the columns of a matrix P (the rows of `P.T`), subtracts from each column its parts along the columns already kept ($e^\dagger v$ is the size of the part of v along the unit column e), and keeps it, divided by its length, when the length that remains is not zero. The subtraction is done twice, because the first pass leaves rounding errors. The kept columns are orthonormal (of length 1 and perpendicular to each other) and span the same space as the columns of P.

```
U_plus = orthonormal_columns((np.eye(16) + h / E) / 2)  # u_1..u_8: energy +5
V_minus = orthonormal_columns((np.eye(16) - h / E) / 2)  # v_1..v_8: energy -5
W = np.hstack([U_plus, V_minus])  # 16 x 16: the columns u_1..u_8, v_1..v_8
report("E for m = 3 and momentum 4 along x1", f"{E:.12f}")
```

Because $hh = E^2\,1$, the matrices $\frac{1}{2}(1 \pm h/E)$ are projectors onto the eigenvectors with the eigenvalues $\pm E$: $h \cdot \frac{1}{2}(1 + h/E) = \frac{1}{2}(h + E\,1) = E \cdot \frac{1}{2}(1 + h/E)$, so every column of the first is an eigenvector with eigenvalue $+E$ (or zero), and in the same way for the second with $-E$. Gram-Schmidt picks eight orthonormal columns from each; `np.hstack` puts them side by side into W. The RESULT line prints $E = 5.000000000000$.

```
check(np.max(np.abs(h - h.conj().T)) < 1e-15
      and np.max(np.abs(h @ h - 25 * np.eye(16))) < 1e-13
      and U_plus.shape == (16, 8) and V_minus.shape == (16, 8)
      and np.max(np.abs(h @ U_plus - E * U_plus)) < 1e-13
      and np.max(np.abs(h @ V_minus + E * V_minus)) < 1e-13
      and np.max(np.abs(W.conj().T @ W - np.eye(16))) < 1e-13
      and np.max(np.abs(W @ W.conj().T - np.eye(16))) < 1e-13,
      "h is Hermitian, h h = 25, with 8 + 8 orthonormal complete eigenvectors")
```

The check: h is Hermitian, $hh = 25 \cdot 1$, eight columns for each energy, $hu_s = 5u_s$ and $hv_s = -5v_s$, and $W^\dagger W = WW^\dagger = 1$ (orthonormal and complete), each to a small floating-point tolerance.

In [8], the field operators and the canonical rule.

```
def basic(i, state):
    p = i % 16  # the mode
    empties = (i < 16) == (p < 8)  # F_p for p < 8 and F_p^* for p >= 8 empty mode p
    return annihilate(p, state) if empties else create(p, state)
```

Every operator used here is a combination of 32 **basic operators** O_i: $O_p = F_p$ and $O_{16+p} = F_p^*$ for $p = 0, \ldots, 15$, where $F_p = b_{p+1} = f_p$ for $p < 8$ (particles) and $F_p = d_{p-7}^* = f_p^*$ for $p \geq 8$ (antiparticles appear in Ψ through their creation operators), and F_p^* is the Hilbert adjoint of F_p. `basic(i, state)` applies O_i: the mode is $p = i \bmod 16$, and O_i empties mode p exactly when ($i < 16$ and $p < 8$) or ($i \geq 16$ and $p \geq 8$), which is what the comparison of the two truth values `(i < 16) == (p < 8)` says.

```
ZEROS = np.zeros((16, 16))
PSI = np.hstack([W, ZEROS])  # row A: Psi_A = sum_p W_Ap F_p
CHI = np.hstack([ZEROS, W.conj()])  # row A: chi_A = sum_p conj(W_Ap) F_p^*
PSI_DAG = B.T @ CHI  # row A: Psi^dagger_A = sum_C chi_C B_CA
```

An operator $\sum_i c_i O_i$ is stored as the row of its 32 coefficients. The field $\Psi_A = \sum_p W_{Ap} F_p$ (Section 5.34 with the columns of W) is row A of `PSI`: the 16 numbers $W_{A,p}$ followed by 16 zeros. Its Hilbert adjoint $\chi_A = \sum_p W_{Ap}^* F_p^*$ is row A of `CHI`. The canonical conjugate $\Psi_A^\dagger = \sum_C \chi_C B_{CA} = \sum_C (B^T)_{AC} \chi_C$ is row A of B^T times `CHI`.

```
def apply(row, state):
    return combine([(row[i], basic(i, state)) for i in range(32)
                    if abs(row[i]) > 1e-15])

def anticommutator(row1, row2, state):
    return combine([(1, apply(row1, apply(row2, state))),
                    (1, apply(row2, apply(row1, state)))])
```

`apply(row, state)` applies the operator of a row to a state (coefficients below 10^{-15} are skipped). `anticommutator(row1, row2, state)` applies $\{X, Y\} = XY + YX$.

```
def measured_rule(rows1, rows2, state):
    norm = inner(state, state).real
    numbers = np.zeros((16, 16), dtype=complex)
    rest = 0.0
    for A in range(16):
        for C_ in range(16):
            result = anticommutator(rows1[A], rows2[C_], state)
            numbers[A, C_] = inner(state, result) / norm
            rest = max(rest, largest(combine([(1, result),
                                              (-numbers[A, C_], state)])))
    return numbers, rest
```

`measured_rule` measures the 256 anticommutators $\{X_A, Y_C\}$ on a state. Each must be a number times the state; the number is read off as $\langle\phi|\{X,Y\}\phi\rangle/\langle\phi|\phi\rangle$, and `rest` keeps the largest amplitude left over after that number times the state is subtracted (it must be zero). The letter `C_` avoids overwriting the matrix `C`.

```
with_chi, rest_chi = measured_rule(PSI, CHI, RANDOM_STATE)
with_dagger, rest_dagger = measured_rule(PSI, PSI_DAG, RANDOM_STATE)
psi_psi, rest_pp = measured_rule(PSI, PSI, RANDOM_STATE)
dag_dag, rest_dd = measured_rule(PSI_DAG, PSI_DAG, RANDOM_STATE)
all_rest = max(rest_chi, rest_dagger, rest_pp, rest_dd)
say("every anticommutator is a number times the state (rest below 1e-12): "
    f"{all_rest < 1e-12}")
```

Four families of anticommutators are measured on the random state: $\{\Psi_A, \chi_C\}$, $\{\Psi_A, \Psi_C^\dagger\}$, $\{\Psi_A, \Psi_C\}$ and $\{\Psi_A^\dagger, \Psi_C^\dagger\}$. The printed line says True: each is a number times the state.

```
check_reproduces(np.max(np.abs(with_chi - np.eye(16))) < 1e-12
                 and np.max(np.abs(with_dagger - B)) < 1e-12
                 and np.max(np.abs(psi_psi)) < 1e-12
                 and np.max(np.abs(dag_dag)) < 1e-12 and all_rest < 1e-12
                 and recorded("wolfram", "Fock_space_good_sector_example"),
                 "{Psi_A, chi_C} = delta_AC and {Psi_A, Psi^dagger_C} = B_AC on the "
                 "positive Fock space; {Psi, Psi} = 0 = {Psi^dagger, Psi^dagger}",
                 record=record_of("wolfram", "Fock_space_good_sector_example"))
```

The check: the measured numbers are the identity for χ, the matrix B for $\Psi^\dagger$, and zero for the other two families, exactly as Section 5.34 derived.

In [9], the picture of the measured rules.

```
def heat_map(ax, matrix, title, row_label=True):
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 3, 7, 11, 15], ["1", "4", "8", "12", "16"])
    ax.set_yticks([0, 3, 7, 11, 15], ["1", "4", "8", "12", "16"])
    ax.axhline(7.5, color="black", linewidth=0.8)
    ax.axvline(7.5, color="black", linewidth=0.8)
    ax.set_xlabel("column")
    if row_label:
        ax.set_ylabel("row")
    ax.grid(False)
    return image
```

The heat map of Notebook 05c, In [4].

```
check(np.max(np.abs(with_chi.imag)) < 1e-12 and np.max(np.abs(with_dagger.real))
      < 1e-12, "the measured numbers are real for chi and imaginary for Psi^dagger")
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
heat_map(axes[0], with_chi.real, r"measured $\{\Psi_A, \chi_C\}$")
```

```
heat_map(axes[1], with_dagger.imag, r"measured $\{\Psi_A, \Psi^\dagger_C\}$ / $i$",
         row_label=False)
image = heat_map(axes[2], B.imag, r"the matrix $B$ / $i$", row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "anticommutators",
            ...)
```

Before drawing, the check confirms what the pictures show: the numbers for χ are real and those for $\Psi^\dagger$ purely imaginary, so the real part of the first and the imaginary part of the second say everything. **What figure 05e.2 shows**: on the left the identity (a red diagonal); in the middle and on the right the same pattern of red and blue squares, B/i, with an empty diagonal. The realisation obeys the canonical rule.

In [10], why the canonical conjugate is not the Hilbert adjoint.

```
u = np.zeros(16, dtype=complex)
u[6], u[15] = -1j / np.sqrt(2), 1 / np.sqrt(2)  # u_7 and u_16 (Python counts from 0)
X_row = u.conj() @ PSI  # X = sum_A conj(u_A) Psi_A
X_adjoint = u @ CHI  # X^* = sum_A u_A chi_A (the Hilbert adjoint)
X_dagger = u @ PSI_DAG  # X^dagger = sum_A u_A Psi^dagger_A (canonical conjugate)
```

The record's column u ($u_7 = -i/\sqrt{2}$, $u_{16} = 1/\sqrt{2}$), the operator $X = \sum_A u_A^* \Psi_A$ as a row (a combination of the rows of `PSI`), its Hilbert adjoint $X^* = \sum_A u_A \chi_A$ and its canonical conjugate $X^\dagger = \sum_A u_A \Psi_A^\dagger$.

```
norm_random = inner(RANDOM_STATE, RANDOM_STATE).real
with_adjoint = inner(RANDOM_STATE, anticommutator(X_row, X_adjoint,
                                                  RANDOM_STATE)) / norm_random
with_canonical = inner(RANDOM_STATE, anticommutator(X_row, X_dagger,
                                                    RANDOM_STATE)) / norm_random
eigen_B = np.linalg.eigvalsh(B)  # the 16 eigenvalues of the Hermitian matrix B
say(f"{{X, X^*}} = {with_adjoint.real:+.6f};  {{X, X^dagger}} = "
    f"{with_canonical.real:+.6f};  u^dagger B u = {(u.conj() @ B @ u).real:+.6f}")
```

The two anticommutators are measured on the random state as numbers, and the 16 eigenvalues of B are computed. In an f-string a doubled brace `{{` prints a single brace. The printed line shows $\{X, X^*\} = +1.000000$, $\{X, X^\dagger\} = -1.000000$ and $u^\dagger B u = -1.000000$.

```
check_reproduces(np.allclose(B @ u, -u) and abs(u.conj() @ B @ u + 1) < 1e-12
                 and abs(with_adjoint - 1) < 1e-12 and abs(with_canonical + 1) < 1e-12
                 and recorded("wolfram", "no_positive_inner_product"),
                 "{X, X^*} = +1 but {X, X^dagger} = u^dagger B u = -1: the canonical "
                 "conjugate needs an indefinite (Krein) inner product",
                 record=record_of("wolfram", "no_positive_inner_product"))
```

The check: $Bu = -u$, $u^\dagger B u = -1$, the anticommutator with the Hilbert adjoint is $+1$ (positive, as it must be), and the canonical one is -1: the argument of Section 5.34 on the computer.

In [11], the picture of the indefinite form.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0))
axes[0].plot(np.arange(1, 17), eigen_B, "o", color="#2a78d6", markersize=8)
axes[0].axhline(0.0, color="black", linewidth=0.8)
axes[0].set_xticks([1, 4, 8, 12, 16])
axes[0].set_xlabel("number of the eigenvalue (sorted)")
axes[0].set_ylabel("eigenvalue of $B$")
axes[0].set_title("$B$: eight eigenvalues $-1$, eight $+1$")
```

The left picture: the 16 sorted eigenvalues of B as dots.

```
axes[1].bar([0, 1], [with_adjoint.real, with_canonical.real],
            color=["#1baf7a", "#eb6834"], edgecolor="white", linewidth=2, width=0.5)
for x_bar, value in zip([0, 1], [with_adjoint.real, with_canonical.real]):
    axes[1].text(x_bar, value + (0.08 if value > 0 else -0.16), f"{value:+.0f}",
                 ha="center")
axes[1].axhline(0.0, color="black", linewidth=0.8)
axes[1].set_xticks([0, 1], [r"$\{X, X^*\}$ (Hilbert adjoint)",
                            r"$\{X, X^\dagger\}$ (canonical)"])
axes[1].set_ylim(-1.5, 1.5)
axes[1].set_ylabel("measured number")
axes[1].set_title("$X = u^\\dagger\\Psi$ with $Bu = -u$")
save_figure(fig, "why_krein",
            ...)
```

The right picture: two bars with their values written beside them. **What figure 05e.3 shows**: on the left eight dots at -1 and eight at $+1$, the signature $(8, 8)$ of B; on the right a green bar up to $+1$ (the Hilbert adjoint) and an orange bar down to -1 (the canonical conjugate). A negative value is impossible for a Hilbert adjoint, which is why the canonical rule needs an indefinite (Krein) inner product.

In [12], the vacuum, the 16 quanta and the expectation-value rule.

```
VACUUM = {0: 1.0}  # the pattern 0: no particle, no antiparticle

def bilinear(L, K, R, state):
    Q = L.T @ K @ R  # 32 x 32: the coefficient of O_i O_j
    terms = []
    for j in range(32):
        if np.max(np.abs(Q[:, j])) > 1e-15:
            lowered = basic(j, state)  # O_j applied first
            if lowered:
                terms += [(Q[i, j], basic(i, lowered)) for i in range(32)
                          if abs(Q[i, j]) > 1e-15]
    return combine(terms)
```

The vacuum is the pattern 0 with amplitude 1. A bilinear $\sum_{A,C} L_A K_{AC} R_C$ of two operators given by rows L_A and R_C is $\sum_{i,j} Q_{ij} O_i O_j$ with the 32×32 matrix $Q = L^T K R$ (insert $L_A = \sum_i L_{Ai} O_i$ and $R_C = \sum_j R_{Cj} O_j$). `bilinear(L, K, R, state)` applies it to a state: for each j with a nonzero column of Q it applies O_j first, and if the result is not the zero state (an empty dictionary counts as false), it applies every O_i with its coefficient.

```
def vacuum_value(L, K, R):
    return inner(VACUUM, bilinear(L, K, R, VACUUM))

QUANTA = [create(p, VACUUM) for p in range(16)]  # b_s^*|0> (p < 8), d_s^*|0>

def normal_ordered_value(L, K, R, state):
    return inner(state, bilinear(L, K, R, state)) - vacuum_value(L, K, R)
```

`vacuum_value` is $\langle 0|X|0\rangle$. `QUANTA` lists the 16 one-quantum states: filling mode p of the vacuum gives $b^*_{p+1}|0\rangle$ for $p < 8$ and $d^*_{p-7}|0\rangle$ for $p \geq 8$. `normal_ordered_value` is $\langle q|X|q\rangle - \langle 0|X|0\rangle$, the value of $:X:$ in a state q of length 1.

```
vacuum_energy = vacuum_value(CHI, h, PSI)
energies = np.array([normal_ordered_value(CHI, h, PSI, q) for q in QUANTA])
vacuum_charge = vacuum_value(PSI_DAG, B, PSI)
charges = np.array([normal_ordered_value(PSI_DAG, B, PSI, q) for q in QUANTA])
report("vacuum energy <0|chi h Psi|0> (the filled sea)", f"{vacuum_energy.real:.6f}")
report("vacuum charge <0|Psi^dagger B Psi|0>", f"{vacuum_charge.real:.6f}")
say("normal-ordered energies of the 16 quanta: "
    + " ".join(f"{e.real:+.0f}" for e in energies))
say("normal-ordered charges of the 16 quanta:  "
    + " ".join(f"{c.real:+.0f}" for c in charges))
```

The energy operator is $\chi h \Psi$ and the charge operator $\Psi^\dagger B \Psi$ (which equals $\chi B B \Psi = \chi \Psi$). The RESULT lines print the vacuum energy -40.000000 ($-8E$, the filled sea) and the vacuum charge 8.000000; the two printed lists show the normal-ordered energy $+5$ for all 16 quanta, and the charge $+1$ for the eight particles and -1 for the eight antiparticles.

```
rule_ok = True
for K_rule in [C, -1j * (C @ gamma["x4"]), -1j * (C @ gamma["x1"])]:
    values = [normal_ordered_value(PSI_DAG, K_rule, PSI, q) for q in QUANTA]
    predicted = ([W[:, s].conj() @ B @ K_rule @ W[:, s] for s in range(8)]
                 + [-(W[:, s].conj() @ B @ K_rule @ W[:, s]) for s in range(8, 16)])
    rule_ok &= np.max(np.abs(np.array(values) - np.array(predicted))) < 1e-12
```

The expectation-value rule of the record: $\langle q| :\Psi^\dagger K \Psi: |q\rangle = u_s^\dagger B K u_s$ for a particle and $-v_s^\dagger B K v_s$ for an antiparticle (`W[:, s]` is column s of W), tested for three of the record's matrices: the scalar, the charge density and the current along $x1$. `&=` keeps `rule_ok` true only while every test passes.

```
check_reproduces(abs(vacuum_energy + 40) < 1e-12 and np.max(np.abs(energies - 5)) < 1e-12
                 and abs(vacuum_charge - 8) < 1e-12
                 and np.max(np.abs(charges - np.array([1] * 8 + [-1] * 8))) < 1e-12
                 and rule_ok and "-8 E" in detail("wolfram",
                                                  "Fock_space_good_sector_example"),
                 "vacuum energy -40, every quantum +5, charges +1 and -1, and the "
                 "expectation-value rule for M = C, -i C gamma^(x4), -i C gamma^(x1)",
                 record=record_of("wolfram", "Fock_space_good_sector_example"))
```

The check collects the numbers and requires that the record's detail text contains `-8 E`, the vacuum energy it states.

In [13], the picture of the quanta.

```
raw_energies = energies + vacuum_energy  # <q|chi h Psi|q>
raw_charges = charges + vacuum_charge  # <q|Psi^dagger B Psi|q>
index = np.arange(1, 17)
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
```

The values in the states before normal ordering are the normal-ordered values plus the vacuum values.

```
for ax, raw, ordered, name in [(axes[0], raw_energies, energies, "energy"),
                               (axes[1], raw_charges, charges, "charge")]:
    ax.bar(index - 0.2, raw.real, 0.4, color="#9e9c98", label="value in the state")
    ax.bar(index + 0.2, ordered.real, 0.4, color="#2a78d6",
           label="after normal ordering")
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.axvline(8.5, color="black", linewidth=0.8, linestyle=":")
    ax.set_xticks([1, 4, 8, 9, 12, 16])
    ax.set_xlabel("quantum: 1 to 8 particles, 9 to 16 antiparticles")
    ax.set_title(f"the {name} of the 16 quanta")
axes[0].set_ylabel("value")
handles, names = axes[0].get_legend_handles_labels()  # one legend for both
fig.legend(handles, names, loc="lower center", bbox_to_anchor=(0.5, -0.1), ncol=2)
save_figure(fig, "quanta",
            ...)
```

For the energy (left) and the charge (right), a grey bar (value in the state) and a blue bar (after normal ordering) for each quantum, and a dotted line between particles and antiparticles; one legend for both pictures (`get_legend_handles_labels` collects the labelled bars of the first picture). **What figure 05e.4 shows**: the grey energy bars at -35 ($= -40 + 5$) and the blue ones at $+5$; the grey charge bars at 9 for particles and 7 for antiparticles, the blue ones at $+1$ and -1. The student should see that the vacuum values are large and that normal ordering subtracts them, leaving the physical numbers.

In [14], the two conjugations of the operators.

```
MAPS = {"M = 1": I16, "M = Gamma": Gamma}  # the two conjugation matrices
conjugated = {}  # name -> (rows of Psi', rows of Psi'^dagger)
measured_conjugated = {}  # name -> the measured {Psi'_A, Psi'^dagger_C}
```

The two maps of Section 5.34 and two dictionaries for the results.

```
for name, M in MAPS.items():
    rows_prime = M @ PSI_DAG  # Psi'_A = sum_C M_AC Psi^dagger_C
    rows_prime_dagger = M.conj() @ PSI  # Psi'^dagger_A = sum_C conj(M_AC) Psi_C
    conjugated[name] = (rows_prime, rows_prime_dagger)
```

```
    numbers, rest = measured_rule(rows_prime, rows_prime_dagger, RANDOM_STATE)
    measured_conjugated[name] = numbers
    predicted = M @ B.T @ M.conj().T
    say(f"{name:9}: measured equals M B^T M^dagger: "
        f"{np.max(np.abs(numbers - predicted)) < 1e-12 and rest < 1e-12}; "
        f"it equals +B: {np.max(np.abs(numbers - B)) < 1e-12}; "
        f"-B: {np.max(np.abs(numbers + B)) < 1e-12}")
```

For each map the rows of the conjugated field and of its canonical conjugate are formed (a matrix times the rows gives the rows of the combinations), the 256 anticommutators are measured on the random state and compared with the prediction $MB^TM^\dagger$. The two printed lines: for $M = 1$ the measurement equals the prediction and $-B$; for $M = \Gamma$ it equals the prediction and $+B$.

```
check_reproduces(np.max(np.abs(measured_conjugated["M = 1"] + B)) < 1e-12
                 and np.max(np.abs(measured_conjugated["M = Gamma"] - B)) < 1e-12
                 and recorded("lead", "quantum_charge_conjugation_unitary_type"),
                 "on the Fock space: Psi' = Psi^(dagger T) gives -B, Psi' = Gamma "
                 "Psi^(dagger T) gives +B: only M = Gamma keeps the canonical rule",
                 record=record_of("lead", "quantum_charge_conjugation_unitary_type"))
```

The check reproduces the lead check on actual operators: of the two maps, only $M = \Gamma$ keeps the canonical rule (Section 5.34 adds that a phase factor $e^{i\alpha}$ in front of Γ changes nothing).

In [15], the picture of the conjugated rules.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
heat_map(axes[0], B.imag, r"$B$ / $i$ (the rule)")
heat_map(axes[1], measured_conjugated["M = 1"].imag,
         r"measured, $M = 1$, / $i$", row_label=False)
image = heat_map(axes[2], measured_conjugated["M = Gamma"].imag,
                 r"measured, $M = \Gamma$, / $i$", row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
save_figure(fig, "conjugated_rules",
            ...)
```

What figure 05e.5 shows: the rule B/i on the left; in the middle, measured for $M = 1$, every colour reversed ($-B$); on the right, measured for $M = \Gamma$, the same picture as on the left. Of the two matrices, only Γ gives a conjugation of the quantised field (up to a phase factor, Section 5.34).

In [16], the conjugated bilinears: a sign and a constant.

```
K_MATRICES = {"S": C.astype(complex)}  # the scalar S = Psi^dagger C Psi
for x in COORDS:
    K_MATRICES[f"J^({x})"] = -1j * (C @ gamma[x])  # the current J^a
BILINEAR_NAMES = list(K_MATRICES)  # "S", "J^(x0)", ..., "J^(x7)"
signs, constants = {}, {}  # (map, bilinear) -> s and c
identity_ok = True
```

The nine matrices: the scalar and the eight currents, under their names.

```
for map_name, M in MAPS.items():
    rows_prime, rows_prime_dagger = conjugated[map_name]
    for bname, K in K_MATRICES.items():
        K_prime = M.conj().T @ K @ M  # K' = M^dagger K M
        c = np.trace(K_prime @ B.T)  # the predicted constant
        s = 1 if np.array_equal(-K_prime.T, K) else (
            -1 if np.array_equal(-K_prime.T, -K) else 0)  # -K'^T = s K
        X_prime = bilinear(rows_prime_dagger, K, rows_prime, RANDOM_STATE)
        X = bilinear(PSI_DAG, K, PSI, RANDOM_STATE)
        difference = combine([(1, X_prime), (-s, X), (-c, RANDOM_STATE)])
        identity_ok &= s != 0 and largest(difference) < 1e-10
        signs[(map_name, bname)], constants[(map_name, bname)] = s, c
```

For each map and each of the nine bilinears: the predicted constant $c = \mathrm{tr}(K' B^T)$ and the predicted sign s with $-K'^T = sK$ (Section 5.34); then the conjugated operator $X' = \Psi'^\dagger K \Psi'$ and the original $X = \Psi^\dagger K \Psi$ are applied to the random state, and the state $X'\phi - sX\phi - c\,\phi$ must vanish. `identity_ok` stays true only if every sign is ± 1 and every difference is below 10^{-10}.

```
for map_name in MAPS:
    say(f"{map_name:9}: s = " + " ".join(f"{signs[(map_name, b)]:+d}"
                                         for b in BILINEAR_NAMES)
        + "  (S, J^(x0), ..., J^(x7))")
    say(f"{'':9}  c = " + " ".join(f"{constants[(map_name, b)].real:+.0f}"
                                   for b in BILINEAR_NAMES))
```

Two lines per map: the nine signs and the nine constants (in the second line the empty string, padded to nine characters, prints nine blanks, so that the two lines line up). The printed result: for $M = 1$ the signs -1 for S and $+1$ for all eight currents, for $M = \Gamma$ the sign -1 for all nine; the constants are 0 except -16 ($M = 1$) and $+16$ ($M = \Gamma$) for $J^{(x4)}$.

```
lead_detail = detail("lead", "bilinears_under_charge_conjugation")
recorded_table = json.loads(lead_detail.split("measured: ", 1)[1])
anticommuting_rows = {"M = 1": recorded_table["plus,eps=-1"],
                      "M = Gamma": recorded_table["minus,eps=-1"]}
rows_agree = all([signs[(m_name, "S")], [signs[(m_name, b)] for b in
                                         BILINEAR_NAMES[1:]]] == row
                 for m_name, row in anticommuting_rows.items())
```

The record's measured table is read as in Notebook 05c, In [14]; its two anticommuting rows (keys `plus,eps=-1` and `minus,eps=-1`) are compared with the operator signs, written in the same shape [sign of S, list of the eight signs of the currents].

```
check(identity_ok, "X' = s X + c holds on the Fock space for all 9 bilinears and both "
      "maps, with c = tr(K' B^T)")
check_reproduces(rows_agree and recorded("lead", "bilinears_under_charge_conjugation"),
                 "the operator signs s equal the measured signs of the anticommuting "
                 "rows (eps = -1) of the recorded table",
                 record=record_of("lead", "bilinears_under_charge_conjugation"))
```

Two checks: the operator identity $X' = sX + c$ (the derivation of Section 5.34, confirmed on the Fock space), and that the operator signs are those of the record's anticommuting rows.

In [17], the constants and the vacuum values.

```
nonzero = sorted({b for (m_name, b), c in constants.items() if abs(c) > 1e-12})
check(nonzero == ["J^(x4)"] and abs(constants[("M = 1", "J^(x4)")] + 16) < 1e-12
      and abs(constants[("M = Gamma", "J^(x4)")] - 16) < 1e-12,
      "c = 0 except for the charge density J^(x4): c = -16 (M = 1), +16 (M = Gamma)")
```

The set of bilinears with a nonzero constant (sorted, so that the printed order never changes) must be the charge density alone, with $c = -16$ and $+16$, as Section 5.34 computed.

```
vac_original = {b: vacuum_value(PSI_DAG, K, PSI) for b, K in K_MATRICES.items()}
vac_conjugated = {}  # (map, bilinear) -> <0|X'|0>
for map_name in MAPS:
    rows_prime, rows_prime_dagger = conjugated[map_name]
    for bname, K in K_MATRICES.items():
        vac_conjugated[(map_name, bname)] = vacuum_value(rows_prime_dagger, K,
                                                         rows_prime)
```

The vacuum values $\langle 0|X|0\rangle$ of the nine original bilinears and $\langle 0|X'|0\rangle$ of the 18 conjugated ones.

```
# values below 1e-12 are printed as 0 (rounding could otherwise print "-0.00")
shown = {b: (v.real if abs(v) > 1e-12 else 0.0) for b, v in vac_original.items()}
say("vacuum values <0|X|0>: " + ", ".join(f"{b} {shown[b]:+.2f}"
                                          for b in BILINEAR_NAMES))
check(all(abs(vac_conjugated[key] - signs[key] * vac_original[key[1]]
              - constants[key]) < 1e-12 for key in vac_conjugated),
      "<0|X'|0> = s <0|X|0> + c for all 9 bilinears and both maps")
```

The printed line lists the vacuum values: S -4.80, $J^{(x1)}$ -6.40, $J^{(x4)}$ $+8.00$ and 0 for the others; the filled sea of the example has a nonzero scalar and a nonzero current along its momentum $x1$. The check: $\langle 0|X'|0\rangle = s\langle 0|X|0\rangle + c$ for all 18 cases (`key[1]` is the name of the bilinear in the pair `key`).

```
positions = np.arange(len(BILINEAR_NAMES))
labels = ["$S$"] + [rf"$J^{{({x})}}$" for x in COORDS]
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.2), sharey=True)
for ax, map_name, title in [(axes[0], "M = 1", r"$\Psi' = \Psi^{\dagger T}$"),
                            (axes[1], "M = Gamma",
                             r"$\Psi' = \Gamma\Psi^{\dagger T}$")]:
    ax.bar(positions - 0.27, [vac_original[b].real for b in BILINEAR_NAMES], 0.27,
           color="#9e9c98", label=r"$\langle 0|X|0\rangle$")
    ax.bar(positions, [vac_conjugated[(map_name, b)].real for b in BILINEAR_NAMES],
           0.27, color="#2a78d6", label=r"$\langle 0|X'|0\rangle$")
    ax.bar(positions + 0.27, [constants[(map_name, b)].real for b in BILINEAR_NAMES],
           0.27, color="#eb6834", label="the constant $c$")
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xticks(positions, labels)
    ax.set_title(title)
```

```
    ax.legend(loc="lower left")
axes[0].set_ylabel("value")
save_figure(fig, "vacuum_values",
            ...)
```

For each map, three bars per bilinear: the vacuum value before (grey) and after (blue) the conjugation, and the constant c (orange). **What figure 05e.6 shows**: for $M = 1$ the scalar's vacuum value changes from -4.8 to $+4.8$, that of $J^{(x1)}$ stays at -6.4, and that of $J^{(x4)}$ goes from 8 to $8 - 16 = -8$; for $M = \Gamma$ all signs flip, and $J^{(x4)}$ goes from 8 to $-8 + 16 = 8$. The orange bars appear only at $J^{(x4)}$. Normal ordering subtracts each operator's own vacuum value, which removes c.

In [18], after normal ordering.

```
def apply_normal_ordered(L, K, R, state):
    return combine([(1, bilinear(L, K, R, state)),
                    (-vacuum_value(L, K, R), state)])
```

`apply_normal_ordered` applies $:X := X - \langle 0|X|0\rangle$ to a state.

```
normal_ok = True
for map_name in MAPS:
    rows_prime, rows_prime_dagger = conjugated[map_name]
    for bname, K in K_MATRICES.items():
        for state in [RANDOM_STATE] + QUANTA:
            left = apply_normal_ordered(rows_prime_dagger, K, rows_prime, state)
            right = apply_normal_ordered(PSI_DAG, K, PSI, state)
            normal_ok &= largest(combine([(1, left),
                                          (-signs[(map_name, bname)], right)])) < 1e-10
check(normal_ok, ":X': = s :X: for all 9 bilinears, both maps, on the random state "
      "and the 16 quanta")
```

For both maps, all nine bilinears and 17 states (the random state and the 16 quanta) the cell compares $:X':$ applied to the state with s times $:X:$ applied to it. The check: normal ordering removes the constant and keeps the sign, everywhere.

```
def classical_sign(M, K, eps):
    new = eps * (M.conj().T @ K @ M).T
    return 1 if np.array_equal(new, K) else (-1 if np.array_equal(new, -K) else 0)

tables = {"commuting components (classical)": 1,
          "anticommuting components (classical)": -1}
grids = {}
for title, eps in tables.items():
    grids[title] = np.array([[classical_sign(M, K_MATRICES[b], eps)
                              for b in BILINEAR_NAMES] for M in MAPS.values()])
grids["quantised field after normal ordering"] = np.array(
    [[signs[(m_name, b)] for b in BILINEAR_NAMES] for m_name in MAPS])
```

`classical_sign` is `sign_of` of Notebook 05c: the classical rule $K' = \epsilon(M^\dagger K M)^T$. Three tables of two rows (the maps) and nine columns (the bilinears) are built: classical commuting, classical anticommuting, and the operator signs of the quantised field.

```
check(np.array_equal(grids["quantised field after normal ordering"],
                     grids["anticommuting components (classical)"])
      and np.array_equal(grids["commuting components (classical)"],
                         -grids["anticommuting components (classical)"]),
      "after normal ordering the quantised field has the signs of the anticommuting "
      "components; the commuting ones are the opposite")
```

The check: the quantised table equals the classical anticommuting one, and the commuting one is its opposite.

```
fig, axes = plt.subplots(3, 1, figsize=(9.0, 6.6))
for ax, (title, grid) in zip(axes, grids.items()):
    ax.imshow(grid, cmap=SIGNS, vmin=-1, vmax=1, aspect="auto")
    for r in range(2):
        for c_col in range(9):
            ax.text(c_col, r, f"{grid[r, c_col]:+d}", ha="center", va="center",
                    color="white", fontweight="bold")
    ax.axhline(0.5, color="white", linewidth=2)
    for k in range(1, 9):
        ax.axvline(k - 0.5, color="white", linewidth=3 if k == 1 else 2)
    ax.set_xticks(range(9), labels)
    ax.set_yticks([0, 1], [r"$\mathcal{C}_+$ type, $M = 1$",
                           r"$\mathcal{C}_-$ type, $M = \Gamma$"])
    ax.set_title(title)
    ax.grid(False)
fig.tight_layout()
save_figure(fig, "sign_tables",
            ...)
```

Three sign tables, one above the other, drawn as in Notebook 05c, In [15] (`c_col` is used as the column counter, because `c` already names a constant); `fig.tight_layout()` spaces the three pictures so that their labels do not overlap. **What figure 05e.7 shows**: the top table (commuting) has a red S and blue currents for $M = 1$ and is all red for $M = \Gamma$; the middle (anticommuting) and the bottom (quantised field after normal ordering) are equal, each the top table with every colour reversed. Normal ordering adds no sign.

In [19], the charges of the quanta after the conjugation.

```
K_charge = K_MATRICES["J^(x4)"]  # equal to B
charge_values = {"original": charges.real}
for map_name in MAPS:
    rows_prime, rows_prime_dagger = conjugated[map_name]
    charge_values[map_name] = np.array(
        [normal_ordered_value(rows_prime_dagger, K_charge, rows_prime, q).real
         for q in QUANTA])
check(np.array_equal(K_charge, B)
      and np.max(np.abs(charge_values["M = Gamma"] + charges.real)) < 1e-12
      and np.max(np.abs(charge_values["M = 1"] - charges.real)) < 1e-12,
      "M = Gamma reverses the normal-ordered charge of every quantum; M = 1 keeps it")
```

The normal-ordered charge density of the conjugated field, $:J'^{(x4)}:$, is evaluated in each of the 16 one-quantum states, for both maps. The check: its matrix is B; with $M = \Gamma$ (the allowed

conjugation) every charge is reversed, particles $+1 \to -1$ and antiparticles $-1 \to +1$; with $M = 1$ (which breaks the canonical rule) every charge stays.

```
fig, ax = plt.subplots(figsize=(8.0, 4.2))
ax.plot(index, charge_values["original"], "o", color="#9e9c98", markersize=12,
        label=r"$:\!J^{(x4)}\!:$ (the field)")
ax.plot(index, charge_values["M = 1"], "s", color="#eb6834", markersize=6,
        label=r"$M = 1$ (breaks the rule)")
ax.plot(index, charge_values["M = Gamma"], "D", color="#2a78d6", markersize=7,
        label=r"$M = \Gamma$ (keeps the rule)")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.axvline(8.5, color="black", linewidth=0.8, linestyle=":")
ax.set_xticks([1, 4, 8, 9, 12, 16])
ax.set_ylim(-1.6, 1.6)
ax.set_xlabel("quantum: 1 to 8 particles, 9 to 16 antiparticles")
ax.set_ylabel("normal-ordered charge")
ax.set_title("The charge of each quantum, and of its conjugates")
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.17), ncol=3)
save_figure(fig, "conjugated_charges",
            ...)
```

Large grey circles for the field, small orange squares (`"s"`) for $M = 1$ and blue diamonds (`"D"`) for $M = \Gamma$. **What figure 05e.8 shows**: the grey circles at $+1$ for quanta 1 to 8 and at -1 for 9 to 16; the orange squares sit inside the circles (unchanged); the blue diamonds are at -1 for the particles and $+1$ for the antiparticles. The one of the two conjugations that keeps the canonical rule exchanges the charges of particles and antiparticles, and, by In [16], it also reverses the scalar and with it the mass.

In [20], the last check.

```
FIGURES = ["05e_1_two_modes.png", "05e_2_anticommutators.png", "05e_3_why_krein.png",
           "05e_4_quanta.png", "05e_5_conjugated_rules.png",

           "05e_8_conjugated_charges.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in FIGURES),
      "the eight figure files of notebook 05e exist")
all_checks_passed()
```

The eight figure files must exist, and the last line reads ALL 18 CHECKS PASSED (notebook 05e): one check each in In [2], In [3], In [4], In [6], In [7], In [8], In [9], In [10], In [12], In [14], In [19] and In [20], and two each in In [16], In [17] and In [18]. Five of them reproduce Revision records (In [8], In [10], In [12], In [14] and the second check of In [16]); the other thirteen are the notebook's own computations.

5.39 What the charge-conjugation matrices say, and do not say, about matter and antimatter

The request that this book answers asks for a theory that "solves matter anti-matter mysteries". The matrices of this chapter are the first tools for that question, so this section states exactly what

they establish and what they do not. Chapter 21 treats the question in full; Chapters 18 and 20 treat the pairs of universes.

What this chapter proves (exact maps between solutions).

- In this theory charge conjugation is a matrix map. With the definition of Section 5.28 (the matrix $M = \mathcal{C}C$ must obey $M(\gamma^a)^* = s\,\gamma^a M$ with one sign s for all eight gammas), there are exactly two charge-conjugation matrices, up to a factor, $\mathcal{C}_+ = C$ (same mass) and $\mathcal{C}_- = \Gamma C$ (mass reversed), and each maps every solution to a solution (Theorem CC, Section 5.28). The converse is not claimed: for $V = 0$ other matrices, such as $P_- C$, also map solutions to solutions.
- For the commuting complex field dirac16complex00, $\mathcal{C}_+$ maps every solution to a solution with the same mass and the opposite charge density (Section 5.29).
- For a real commuting field the currents vanish, $\mathcal{C}_+$ does nothing, and among the matrices that obey the intertwiner condition the only nontrivial one is Γ (up to a factor), with $(m, \lambda) \to (-m, -\lambda)$ (Section 5.29).
- For the quantised anticommuting field dirac16complex, among the matrices of Theorem CC only $\Psi \to \Gamma\Psi^{\dagger T}$, up to a phase factor, keeps the canonical anticommutator; after normal ordering it reverses the charge of every quantum and reverses the mass (Section 5.34).
- The map $\Psi \to \Gamma\Psi$ keeps the scalar and reverses every current (Section 5.5, (X7) and (X8)); it carries a solution with the parameters (m, λ) to one with $(-m, -\lambda)$ (Section 5.29, (F3); this is the input of the pairing theorem T1, which Chapter 18 proves). So a solution and its Γ image carry opposite charges, and the two together have total charge zero.
- The current obeys the local conservation law $\sum_\mu \partial_\mu(\sqrt{|g|}\, J^\mu) = 0$, $\sqrt{|g|} = b_4^{3/2} \cos z$, for every solution (record checks `u1_noether_matrix_identity` at $b_4 = 1$ and `u1_noether_matrix_identity_b4` for a general b_4, derived in Chapter 21): no process described by these field equations creates or destroys charge at any point; charge can only flow from one place to another. Hence the total charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, d^7x$ of one solution (at $b_4 = 1$; for a general b_4 it carries the factor $b_4^{3/2}$) is constant in time **if** its current flux through the boundary of the seven other directions vanishes (Section 5.6); this is a conditional statement, and its condition is not established (next list).

All of these are exact statements about **maps between sets of solutions** of the field equations.

What is not proved, and is not claimed.

- Nothing in this chapter shows that any universe is **created**, in pairs or otherwise. The maps relate solutions that are both allowed by the equations; they contain no creation process, no rate, no amplitude and no big-bang dynamics (Chapter 20).
- It is not proved that the total charge of one universe is constant in time. That needs the **no-flux condition** at the brane, $\cos z\, J^{x0} = 0$ at $z = \pi/2$, and the flux there is not zero in general (Section 5.6): exact solutions of Section 18.21, for example the one of Notebook 18c, carry charge through the brane, while the stationary members of that family do not. The condition is not derived for every solution (OPEN); the Kohn-Sham model of Chapter 14

ASSUMES it, through the Z2 mirror at the brane; the statement that no net charge is made inside one universe holds only where it is ASSUMED.

- The theory as built does **not** solve the matter–antimatter problem. The observed universe contains far more matter than antimatter (Chapter 21 explains the measurement from zero). In 1967 Sakharov showed that producing such an excess from a symmetric start needs three things: a process that changes the baryon number (roughly, the number of protons and neutrons minus the number of their antiparticles), a violation of the symmetries C and CP, and a departure from thermal equilibrium (Chapter 21 derives the three conditions). The theory as built has no baryons, no process that creates or destroys a charge at any point (the current obeys the local conservation law; the total Q of one universe is constant only under the no-flux condition at the brane, which is ASSUMED, not derived), no violation of CP built in or computed, and no computation of a departure from equilibrium. Chapter 21 lists what would have to be added.

- The idea that a universe and an anti-universe together carry zero charge belongs to a class of ideas in the published literature; one example is L. Boyle, K. Finn and N. Turok, "CPT-Symmetric Universe", Phys. Rev. Lett. 121, 251301 (2018). The pair-level statement above (a solution and its Γ image have total charge zero) is a statement of this kind about solutions. Any scenario in which our universe is one member of such a pair, or in which the pairing explains the observed excess of matter, is a **HYPOTHESIS**: nothing in this chapter or in the Revision record derives it.

5.40 What we proved, what we computed, what we assumed

PROVED (exact; the proof is in this chapter, and where a Revision record holds the fact, the report and check named confirm it independently; the notebooks named confirm it again):

- Six rules for products of different gammas (moving a gamma through a product, the square, the reverse, the transpose, the trace 0, the count of eigenvalues); the properties of $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$ ((C1) to (C7): symmetric, $CC = 1$, $C\gamma^a$ antisymmetric, $C\gamma^a C^{-1} = -(\gamma^a)^T$, signature $(8,8)$, $C = \mathrm{diag}(-\sigma, \sigma)$), of the chirality Γ ((X1) to (X9), $\Gamma = \mathrm{diag}(-1_8, 1_8)$, $\Gamma^T C\Gamma = C$, $\Gamma^T C\gamma^a\Gamma = -C\gamma^a$) and of $B = -iC\gamma^{(x4)}$ ((B1) to (B5): Hermitian, $BB = 1$, signature $(8,8)$, commuting with five gammas and anticommuting with the three of the extra times) (Sections 5.3 to 5.6; Notebook 05a; `Revision/algebra/reports/python-algebra.json` and `Revision/algebra/reports/wolfram-algebra.json`, the checks named in the tables of those sections).

- Theorem P: the 16 components carry an irreducible representation of Pin(4,4), and only the multiples of 1 commute with it; Theorem S: under Spin(4,4) they split into two irreducible, inequivalent halves of 8, and the commutant is spanned by P_- and P_+; the same holds for the 28 generators S^{ab} (Section 5.13; Notebook 05b; checks `clifford_products_span_M16`, `pin_commutant_dimension_1`, `even_products_span_M8_plus_M8`, `spin_commutant_dimension_2`, `spin_halves_irreducible`, `spin_halves_inequivalent`, `reflections_exchange_halves`).

- The so(4,4) rules, the vector rule, the key identity of reflections, the closed formulas of the exponentials, the half angle and $R(2\pi) = -1$, the invariance of the scalar under products

of exponentials, the form of B kept by exactly the 21 generators without $x4$, the spinor norm $g^T C g = (-1)^k N(g)\, C$, the double cover (the vector matrix fixes g up to the sign), and determinant $+1$ for every element of Pin(4,4) (Sections 5.12 and 5.18; Notebook 05d; checks `S_lorentz_algebra`, `S_vector_action`, `S_preserves_C_and_commutes_with_Gamma`, `S_preserves_B_only_off_x4`).

- What the scaled commutators generate: the products of their exponentials form exactly $\mathrm{Spin}_0(4,4)$, the piece of Pin(4,4) joined to 1; Pin(4,4) consists of four pieces, Spin_0, $\mathrm{Spin}_0\gamma^{(x0)}$, $\mathrm{Spin}_0\gamma^{(x4)}$ and $\mathrm{Spin}_0\gamma^{(x0)}\gamma^{(x4)}$; together with $\gamma^{(x0)}$ and $\gamma^{(x4)}$ the exponentials generate all of Pin(4,4) (Section 5.23; Notebook 05f).

- The local conservation law $\sum_\mu \partial_\mu(\sqrt{|g|}\, J^\mu) = 0$ of the record, $\sqrt{|g|} = b_4^{3/2} \cos z$, and from it the conditional statement: the total charge Q is constant in time for every solution whose current flux through the boundary of the seven other directions vanishes (Section 5.6; check `u1_noether_matrix_identity` of the lead report at $b_4 = 1$, whose detail text states that it proves the local law only, and check `u1_noether_matrix_identity_b4` of `Revision/theory/reports/python-field-theory-b4.json` for a general b_4). The flux through the brane $z = \pi/2$ is not zero in general, so the constancy of Q itself is not proved (see OPEN); it is zero for the stationary members $e^{iwx4}\chi$ of the family of exact solutions of Section 18.21, whose charge density is the same at every time (Section 5.6).

- Steps 1 to 4 of Section 5.28: every matrix M with $M(\gamma^a)^* = s\,\gamma^a M$ (one sign s for all a) maps every solution Ψ to the solution $M\Psi^*$ with sV; for $V = 0$ the matrix $P_- C$ maps every solution to a solution without obeying this condition. Theorem CC: with the condition as the definition, exactly two charge-conjugation matrices, up to a factor, $\mathcal{C}_+ = C$ (same mass, $\Psi^c = \Psi^*$) and $\mathcal{C}_- = \Gamma C$ (mass reversed, $\Psi^c = \Gamma\Psi^*$), with $\mathcal{C}_\pm^{-1}\gamma^a\mathcal{C}_\pm = \mp(\gamma^a)^T$; the sign table of the scalar and the currents for commuting and anticommuting components; both reality conditions consistent, the real one kept in time and the other only for $m = 0$; for real fields $J = 0$, $\mathcal{C}_+$ the identity and, among the matrices that obey the condition, Γ the nontrivial map with $(m, \lambda) \to (-m, -\lambda)$ (Sections 5.28 and 5.29; Notebook 05c; the lead report of charge conjugation, with the checks named in the tables of those two sections).

- For the quantised field: the canonical conjugate cannot be a Hilbert adjoint; among the matrices of Theorem CC only $\Psi \to \Gamma\Psi^{\dagger T}$, up to a phase factor, keeps the canonical anticommutator; every conjugated bilinear is $X' = sX + c$ with the sign of the classical anticommuting components and the constant $c = \mathrm{tr}(K'B^T)$; normal ordering removes c and keeps s (the detail text of the lead check `bilinears_under_charge_conjugation` states the same: normal ordering adds no sign); the allowed conjugation reverses the charge of every quantum and the mass (Section 5.34; Notebook 05e; checks `quantum_charge_conjugation_unitary_type` of the lead report and `no_positive_inner_product` of `Revision/theory/reports/wolfram-field-theory.json`).

COMPUTED (floating-point numbers, with the measured accuracy, or exact computations of the notebooks): the quadratic form of C along two paths, $\mp\sin 2t$ to 10^{-14} (05a); the exact ranks 256 and 128 of the products of different gammas, the commutant and intertwiner dimensions 1, 2, 1, 1, 0, 0 by exact ranks and again by the zero eigenvalues of $A^T A$, the halving sequence $256, 128, \ldots, 1$ and the negative control 4 (05b); the vector matrices and the closed formulas to 10^{-10} or better (05d); the sign pattern $(+,+)$ on 200 random products of exponentials (smallest determinant 1.000, reached by a product of six rotations), the four patterns on 240 random elements, ten paths that never

cross the band, the construction of step (I) on 40 random unit vectors and the decomposition of 12 random elements of Pin(4,4), and the spans 128 and 256 by singular values (05f); the exact solution spaces of the 2048 equations for each sign and the residuals of the free solution, below 10^{-12} where it solves and 11.83 where it does not, the values $S = -2$ and $J^{(x4)} = -6$, $+6$, -6 of the free solution and its images (exact at $x4 = 0$), and the violation $2|\sin(m\,x4)|$ of the condition $\Psi = \Gamma\Psi^*$ (05c); on the Fock space of 65536 states, the canonical rule to 10^{-12}, the vacuum energy -40, the energies $+5$ and the charges ±1, the vacuum values $S = -4.80$, $J^{(x1)} = -6.40$, $J^{(x4)} = 8$, the constants $c = \mp16$, and the reversed charges of the 16 quanta (05e). One observation is COMPUTED only and not used: $|\det A| = |\det D|$ for the 240 elements of Notebook 05f.

ASSUMED: the author's gammas, built from his formulas for T16 (Chapter 4), his coordinates and his metric (the input of the whole theory); the field equation $\gamma^\mu D_\mu \Psi = V\Psi$ of the Revision record (Chapter 7) and its canonical quantisation (Chapter 10); the theorem of Cartan and Dieudonné (every matrix of O(4,4) is a product of reflections), quoted without proof; three facts of analysis quoted without proof (the power series of the exponential converges for every square matrix; a linear differential equation has only one solution with a given starting value; the intermediate value theorem); and, for Notebook 05e, the scope of the example: one momentum without extra-time part, at one point of space, with the metric treated as flat near that point (the record's frozen-coefficient plane waves: constant gammas, no spin-connection term), and with the Fock vacuum of that momentum.

HYPOTHESIS and OPEN: this chapter derives no creation of universes and no explanation of the matter–antimatter asymmetry; every scenario built on the maps of this chapter is a HYPOTHESIS (Section 5.39). OPEN: the no-flux condition $\cos z\, J^{x0} = 0$ at the brane $z = \pi/2$, which a constant total charge of one universe needs; no equation of the Revision record or of this book derives it for every solution, and the field equations and the quantisation of the record impose no condition at the brane; the Kohn-Sham model of Chapter 14 ASSUMES the Z2 mirror at the brane, whose two conditions make the current along the hidden direction zero there (`Revision/kohn_sham/ks-theory.json`, entry `boundaryConditions.brane`); exact solutions of Section 18.21, for example the one of Notebook 18c, violate it, while the stationary members of that family obey it (Section 5.6); wherever a constant total charge is used, it is ASSUMED. RESOLVED on 2026-10-08: an earlier version of the detail text of the lead check `bilinears_under_charge_conjugation` said that normal ordering supplies one more sign for each bilinear; the derivation of Section 5.34 (PROVED) and the Fock-space computation of Notebook 05e (COMPUTED) contradicted it, and the record was corrected: it now states that normal ordering adds no sign, in agreement with this chapter. OPEN, not studied in this book: whether, for $V \neq 0$ in the author's metric, some matrix that does not obey the intertwiner condition maps every solution to a solution (Section 5.28; nothing in this chapter depends on it).

5.41 Exercises

Exercise 1. Use only the table of Section 5.6. (a) Read off the entries $C_{1,5}$ and $(\Gamma C)_{1,5}$, and $C_{9,13}$ and $(\Gamma C)_{9,13}$, and explain them with $\Gamma = \mathrm{diag}(-1_8, 1_8)$. (b) Show that $(\Gamma C)_{5,1} = (\Gamma C)_{1,5}$, as the symmetry of $\mathcal{C}_-$ demands. (c) Which entry of σ do the entries $(\Gamma C)_{1,5}$ and $(\Gamma C)_{9,13}$ correspond to?

Answer. (a) Row 1 of C reads -5: $C_{1,5} = -1$. Multiplying by Γ from the left multiplies row r by the diagonal entry Γ_{rr}, which is -1 for $r = 1$; so $(\Gamma C)_{1,5} = (-1)(-1) = +1$, and the table indeed shows $+5$ in row 1 of ΓC. Row 9 of C reads $+13$: $C_{9,13} = +1$; $\Gamma_{99} = +1$, so $(\Gamma C)_{9,13} = +1$, and the table

shows +13. (b) Row 5 of ΓC reads +1: $(\Gamma C)_{5,1} = +1 = (\Gamma C)_{1,5}$. (c) σ has 1_4 in its two off-diagonal blocks, so $\sigma_{1,5} = 1$. In $\Gamma C = \mathrm{diag}(\sigma, \sigma)$ the top-left block is σ itself, so $(\Gamma C)_{1,5} = \sigma_{1,5} = 1$; the bottom-right block starts at row and column 9, so $(\Gamma C)_{9,13} = \sigma_{1,5} = 1$ as well.

Exercise 2. Without a computer, show that $\mathcal{C}_+^{-1}\gamma^{(x4)}\mathcal{C}_+ = +\gamma^{(x4)}$ and $\mathcal{C}_-^{-1}\gamma^{(x4)}\mathcal{C}_- = -\gamma^{(x4)}$, and check that both agree with Theorem CC (c).

Answer. By (C1) with $\eta_{x4\,x4} = -1$, $C\gamma^{(x4)} = \gamma^{(x4)}C$. So $\mathcal{C}_+^{-1}\gamma^{(x4)}\mathcal{C}_+ = C\gamma^{(x4)}C = \gamma^{(x4)}CC = \gamma^{(x4)}$, using $CC = 1$ (C3). Theorem CC (c) says it is $-(\gamma^{(x4)})^T$, and indeed $(\gamma^{(x4)})^T = -\gamma^{(x4)}$ (the time-like gammas are antisymmetric), so $-(\gamma^{(x4)})^T = \gamma^{(x4)}$. For $\mathcal{C}_-$: $\mathcal{C}_-^{-1}\gamma^{(x4)}\mathcal{C}_- = C\Gamma\gamma^{(x4)}\Gamma C = -C\gamma^{(x4)}\Gamma\Gamma C = -C\gamma^{(x4)}C = -\gamma^{(x4)}$, by (X2), (X1) and the first part; Theorem CC (c) says $+(\gamma^{(x4)})^T = -\gamma^{(x4)}$. Both agree.

Exercise 3. Take $\Psi_0 = e_1$, the column with 1 in row 1 and 0 elsewhere. (a) Using the table of the time-like gammas in Section 5.2, find $\gamma^{(x4)}e_1$ and write the free solution $\Psi(x4)$ of Section 5.28. (b) Write Ψ^* and $\Gamma\Psi^*$ and say which mass each belongs to. (c) Compute $S = \Psi^T C\Psi$ and $J^{(x4)}$ of Ψ with the table of Section 5.6. What do the answers illustrate?

Answer. (a) $\gamma^{(x4)}e_1$ is column 1 of $\gamma^{(x4)}$. The table lists, for each row, the column of its nonzero entry; row 14 of $\gamma^{(x4)}$ reads +1, so the only nonzero entry of column 1 is +1 in row 14: $\gamma^{(x4)}e_1 = e_{14}$. So $\Psi(x4) = \cos(m\,x4)\,e_1 - \sin(m\,x4)\,e_{14}$. (b) Ψ is real, so $\Psi^* = \Psi$: the same-mass conjugate is the field itself (mass m). Γ is -1 in row 1 and $+1$ in row 14, so $\Gamma\Psi^* = -\cos(m\,x4)\,e_1 - \sin(m\,x4)\,e_{14}$. With $\Phi_0 = \Gamma e_1 = -e_1$ the solution formula with mass $-m$ gives $\cos(-m\,x4)\Phi_0 - \sin(-m\,x4)\gamma^{(x4)}\Phi_0 = -\cos(m\,x4)\,e_1 + \sin(m\,x4)\,(-e_{14})$, the same column: $\Gamma\Psi^*$ belongs to the mass $-m$. (c) $S = \cos^2(m\,x4)\,C_{1,1} - \cos(m\,x4)\sin(m\,x4)\,(C_{1,14} + C_{14,1}) + \sin^2(m\,x4)\,C_{14,14}$. Row 1 of C points to column 5 and row 14 to column 10, so all four entries are 0 and $S = 0$. In the same way row 1 of B/i points to column 10 and row 14 to column 5, so $B_{1,1} = B_{1,14} = B_{14,1} = B_{14,14} = 0$ and $J^{(x4)} = 0$. The example illustrates Section 5.29: a real field carries no charge, $\mathcal{C}_+$ does nothing to it, and the map $\Psi \to \Gamma\Psi$ of the other charge-conjugation matrix $\mathcal{C}_- = \Gamma C$ gives a different real solution with the mass reversed.

Exercise 4. Take the complex column $\Psi = e_1 + e_5 + i\,e_{10}$. (a) Compute $S = \Psi^\dagger C\Psi$ and $J^{(x4)} = \Psi^\dagger B\Psi$ with the table of Section 5.6. (b) Do the same for Ψ^* and for $\Gamma\Psi^*$, and compare with the commuting rows of the sign table of Section 5.29.

Answer. (a) $S = \sum_{r,c}\Psi_r^* C_{rc}\Psi_c$ needs the entries of C between the rows and columns 1, 5, 10. Row 1 of C points to 5 with $-$ ($C_{1,5} = -1$), row 5 to 1 with $-$ ($C_{5,1} = -1$), row 10 to 14 (not among them). So $S = \Psi_1^* C_{1,5}\Psi_5 + \Psi_5^* C_{5,1}\Psi_1 = (1)(-1)(1) + (1)(-1)(1) = -2$. For B: row 1 of B/i points to 10 with + ($B_{1,10} = +i$), row 10 to 1 with $-$ ($B_{10,1} = -i$), row 5 to 14 (not among them). So $J^{(x4)} = \Psi_1^* B_{1,10}\Psi_{10} + \Psi_{10}^* B_{10,1}\Psi_1 = (1)(i)(i) + (-i)(-i)(1) = -1 - 1 = -2$. (b) $\Psi^* = e_1 + e_5 - i\,e_{10}$: S involves only the real components 1 and 5, so $S = -2$; $J^{(x4)} = (1)(i)(-i) + (i)(-i)(1) = 1 + 1 = +2$. $\Gamma\Psi^* = -e_1 - e_5 - i\,e_{10}$ ($\Gamma = -1$ in rows 1 and 5, +1 in row 10): $S = (-1)(-1)(-1) + (-1)(-1)(-1) = -2$; $J^{(x4)} = (-1)(i)(-i) + (i)(-i)(-1) = -1 - 1 = -2$. So $\mathcal{C}_+$ keeps S and reverses $J^{(x4)}$, and $\mathcal{C}_-$ keeps both: the commuting rows of the table.

Exercise 5. For a fixed angle α, consider the condition $\Psi = e^{i\alpha}\Psi^*$. (a) Show that it is consistent in the sense of Section 5.29. (b) Find all columns that obey it. (c) Why does this not contradict the statement that there are only two charge-conjugation matrices?

Answer. (a) Here $M = e^{i\alpha}1$ and $MM^* = e^{i\alpha}e^{-i\alpha}1 = 1$: consistent. (b) Write $\Psi = e^{i\alpha/2}u$ with $u = e^{-i\alpha/2}\Psi$. Then $e^{i\alpha}\Psi^* = e^{i\alpha}e^{-i\alpha/2}u^* = e^{i\alpha/2}u^*$, so the condition reads $e^{i\alpha/2}u = e^{i\alpha/2}u^*$, that is

$u = u^*$: the solutions are the columns $e^{i\alpha/2}u$ with u real. (c) Theorem CC finds the matrices up to a factor; $e^{i\alpha}1$ is a multiple of 1. The condition is the reality condition of $\mathcal{C}_+$ for the field $e^{-i\alpha/2}\Psi$, which differs from Ψ only by a constant phase.

Exercise 6. With the sign rule of Section 5.34 compute $f_1^* f_0^* |00\rangle$ and $f_0^* f_1^* |00\rangle$ for two modes, and show that f_0^* and f_1^* anticommute on this state.

Answer. $f_0^*|00\rangle = |10\rangle$ (no mode below mode 0, sign +). Then $f_1^*|10\rangle$ fills mode 1; mode 0 below it is full, so the sign is $(-1)^1$: $f_1^*|10\rangle = -|11\rangle$. Hence $f_1^* f_0^*|00\rangle = -|11\rangle$. In the other order, $f_1^*|00\rangle = |01\rangle$ (mode 0 below is empty, sign +), and $f_0^*|01\rangle = |11\rangle$ (no mode below mode 0). Hence $f_0^* f_1^*|00\rangle = |11\rangle$. The sum is $\{f_0^*, f_1^*\}|00\rangle = -|11\rangle + |11\rangle = 0$.

Exercise 7. (a) Compute the constant $c = \mathrm{tr}(K'B^T)$ of Section 5.34 for the scalar ($K = C$) and the map $M = 1$. (b) Compute it for the charge density ($K = B$) and the map $M = \Gamma$. (c) The vacuum value of the charge density in the example of Notebook 05e is $\langle 0|J^{(x4)}|0\rangle = 8$. What is $\langle 0|J'^{(x4)}|0\rangle$ for $M = \Gamma$, and what is the normal-ordered result?

Answer. (a) $K' = C$ and $B^T = -B = iC\gamma^{(x4)}$, so $K'B^T = iCC\gamma^{(x4)} = i\gamma^{(x4)}$ by $CC = 1$, and $c = i\,\mathrm{tr}\,\gamma^{(x4)} = 0$ (Rule 5). (b) $K' = \Gamma B \Gamma = -B$ (Section 5.34), so $K'B^T = -B(-B) = BB = 1$ and $c = \mathrm{tr}\,1 = 16$. (c) For $M = \Gamma$ every sign is $s = -1$, so $\langle 0|J'^{(x4)}|0\rangle = s\langle 0|J^{(x4)}|0\rangle + c = -8 + 16 = 8$. After normal ordering, $:J'^{(x4)}: = J'^{(x4)} - 8 = (-J^{(x4)} + 16) - 8 = -(J^{(x4)} - 8) = -:J^{(x4)}:$: the constant is gone and the sign -1 stays, so every charge is reversed, as figure 8 of Notebook 05e shows.

Exercise 8. (a) Show that $\exp(\pi S^{(x4)(x5)}) = \gamma^{(x4)}\gamma^{(x5)}$. (b) Compute the spinor norm of $g = \gamma^{(x4)}\gamma^{(x5)}$ and check $g^T C g = C$. (c) Do the same for $h = \gamma^{(x1)}\gamma^{(x4)}$ and explain, with Section 5.23, why h is not a product of exponentials although it lies in Spin(4,4).

Answer. (a) $x4$ and $x5$ are both time-like, so $\eta_{x4\,x4}\eta_{x5\,x5} = +1$ and the plane is a rotation plane; the closed formula of Section 5.18 gives $\exp(\theta S^{(x4)(x5)}) = \cos\frac{\theta}{2}\,1 + \sin\frac{\theta}{2}\,\gamma^{(x4)}\gamma^{(x5)}$, and at $\theta = \pi$, $\cos\frac{\pi}{2} = 0$ and $\sin\frac{\pi}{2} = 1$. (b) g is a product of $k = 2$ unit vectors e_{x4} and e_{x5} with $\eta(e_{x4}, e_{x4}) = \eta(e_{x5}, e_{x5}) = -1$, so $N(g) = (-1)(-1) = +1$ and $g^T C g = (-1)^2 N(g)\, C = C$, as for every product of exponentials. (c) For h, $N(h) = \eta(e_{x1}, e_{x1})\,\eta(e_{x4}, e_{x4}) = (+1)(-1) = -1$, so $h^T C h = -C$. Every product of exponentials keeps C (Section 5.18), so h is not one. In the language of Section 5.23: $\Lambda(h)$ reverses $x1$ and $x4$, so its space block has determinant -1 and its time block -1; the sign pattern is $(-,-)$, the piece $\mathrm{Spin}_0\,\gamma^{(x0)}\gamma^{(x4)}$, while the products of exponentials have the pattern $(+,+)$. Since h has two factors, it is even and lies in Spin(4,4).

6 Spinors in curved 4+4 space: vielbein, spin connection and $\gamma^\mu\Omega_\mu$

The two fields of the author, dirac16complex and dirac16complex00, have sixteen components at every point of spacetime. Chapters 4 and 5 built the eight gamma matrices that act on these components and the groups Pin(4,4) and Spin(4,4) that turn them. All of that was done in flat 4+4 space, where the eight directions are the same at every point. The author's universe is not flat: 3-space inflates, the three extra times deflate exponentially, and the hidden direction is warped. This chapter teaches, from zero, how a field with sixteen components is differentiated in such a curved space, and it computes exactly what gravity puts into the field equations of the author's two fields through the canonical spin connection. The answer is one 16×16 matrix, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$, which is $3H\gamma^{(x0)}$ on the backgrounds of this book ($b_4 = 1$), and

the chapter also proves precisely what this matrix does and does not mean.

6.1 What this chapter does

The problem in plain words. A spinor field Ψ is a list of sixteen numbers at every point. The numbers are not measured in the coordinates $x_0, \ldots, x_7$ directly: they are measured with respect to eight perpendicular unit directions chosen at each point, a **frame**. In flat space one frame serves everywhere. In a curved space the frame of one point and the frame of a neighbouring point are turned with respect to each other, so the plain derivative $\partial_\mu \Psi$ mixes two things: how the field really changes, and how the frame turns. The **spin connection** measures how the frame turns, and the **covariant derivative** $D_\mu \Psi = \partial_\mu \Psi + \Omega_\mu \Psi$ removes the turning. The field equation of both fields (Chapter 7 derives it) is

$$\sum_\mu \gamma^\mu D_\mu \Psi = \big(m + U'(S)\big)\Psi,$$

and the spin connection enters it only through the one matrix $\sum_\mu \gamma^\mu \Omega_\mu$. The author asked that the field equations "always possess non-zero contributions from gravity (through the canonical spin-connection, unless we are in flat 4+4 spacetime)" (quoted from `Revision/README.md`). This chapter computes the matrix exactly and examines the request line by line.

What the chapter proves.

- The author's metric, with its two functions $a_4(x_4)$ and $b_4(x_4)$, has a diagonal vielbein (Section 6.2), 25 independent nonzero Christoffel symbols (Section 6.3) and a canonical spin connection with 12 independent nonzero components (Sections 6.4 to 6.6).
- The spinor connection Ω_μ makes the curved gammas covariantly constant (Section 6.7), and in the diagonal vielbein $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ for every $H > 0$ and all functions $a_4(x_4)$ and $b_4(x_4) > 0$: the a_4' terms along the time $x4$ of the three inflating directions and of the three deflating extra times cancel exactly, a changing b_4 leaves the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$, and the six terms along the hidden direction add up to $3H\gamma^{(x0)}$ (Sections 6.8 and 6.9). For a constant b_4, as on the backgrounds of this book, the matrix is $3H\gamma^{(x0)}$.
- This matrix sends a nonzero field to zero only where $|b_4'/b_4| = 4H$, never for a constant b_4 (Section 6.10).
- A **negative control**: if the extra times inflated instead of deflating, a term $3a_4'\gamma^{(x4)}$ would survive; the cancellation of the a_4' terms is caused by the deflation (Section 6.10).
- The value of $\gamma^\mu \Omega_\mu$ belongs to the chosen frame: in another frame of the same metric the contraction is $\frac{6H-\beta}{2}(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}) + \frac{3}{4}\frac{b_4'}{b_4}(\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)})$ and vanishes for $\beta = 6H$ when b_4 is constant (Sections 6.15 and 6.16), and a rescaling of the field removes it (Section 6.18). What no frame and no rescaling can remove is the curvature: $R^{x0}{}_{x0} = -6H^2$ for every $H > 0$ and every b_4 (Section 6.17).
- Why the record contracts the spin connection with both frame indices down: the author's notebook contracts the mixed components, which lacks a metric factor; that contraction

deletes all 16 boost parts of the connection and would give $\frac{3H}{2}\gamma^{(x0)} + \frac{3}{2}(a'_4 - \frac{b'_4}{2b_4})\gamma^{(x4)}$ (Sections 6.23 and 6.24).

The three worked examples. Each is a complete Jupyter notebook; the chapter places each one where its theory has been explained, gives the complete instructions to run it, prints its complete text and then explains every line of its code.

notebook	**what it computes**	**figures**	**checks**
06a	vielbein, Christoffel symbols, spin connection, Ω_μ, the contraction $\gamma^\mu\Omega_\mu$ direction by direction, the divergence form, the Dirac operator, the negative control, a warm-up in the plane	10	36
06b	a boosted frame, local spin covariance, the Riemann and Ricci tensors, the spinor curvature, the rescaling	6	26
06c	the mixed contraction of the author's notebook and what the missing metric factor changes	6	27

All three reproduce the Revision record where they overlap with it; every such check prints a second line that names the record file and its check. Their last lines are ALL 36 CHECKS PASSED (notebook 06a), ALL 26 CHECKS PASSED (notebook 06b) and ALL 27 CHECKS PASSED (notebook 06c).

Statuses. Every statement carries one of the five labels of Chapter 0. **PROVED**: derived exactly here, line by line, and confirmed by an exact check of a notebook; where the Revision record proves the same, the record file and its check are named. **COMPUTED**: a number obtained by a notebook, with its accuracy. **ASSUMED**: the author's metric itself (the input of the theory), two standard theorems that are quoted and named where they are used, and the illustrative histories used only in some plots: $a_4 = x_4$ with $b_4 = 1$ (and $H = 1$), which is the prescribed background of Chapter 3 with slope $A = 1$, and in one plot $b_4 = 1 + \frac{1}{2}\sin x_4$. No HYPOTHESIS enters this chapter, and nothing in it is OPEN except the choice of boundary condition at the patch end, which Section 6.24 names and Chapter 14 treats. Nothing in this chapter concerns pairs of universes, their creation, or matter and antimatter; Chapters 18 to 21 treat those questions and state exactly what is and what is not proved about them.

Notation. The eight directions are named $x0, \ldots, x7$ as in Chapter 5: $x0$ is the hidden direction, $x1, x2, x3$ are 3-space (inflating), $x4$ is the time, $x5, x6, x7$ are the three extra times (time-like, deflating exponentially). Inside formulas the coordinate values are written $x_0, \ldots, x_7$, for example

$z = 6Hx_0$ with $0 < z < \pi/2$. The letter i stands for one of the 3-space directions $x1, x2, x3$ and the letter t for one of the extra times $x5, x6, x7$ (except in the polar plane, where i is the imaginary unit, and in Section 6.16, where t is a component). The functions a_4 and $b_4 > 0$ depend on x_4 only; $a_4' = da_4/dx_4$, $a_4'' = d^2a_4/dx_4^2$, and the same for b_4. As in Chapter 3, $\alpha = a_4'$ is the expansion rate of 3-space and $\alpha_t = -a_4' + b_4'/(2b_4)$ the expansion rate of the extra times ($\alpha_t = -a_4'$ when b_4 is constant). On the backgrounds of this book $b_4 = 1$ (Chapter 3: an empty spacetime has a constant b_4, and a constant b_4 only rescales $x5, x6, x7$); every formula of this chapter holds for every b_4 unless it says otherwise. The frame metric is

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

in the order $x0, \ldots, x7$; η_{aa} is its entry for the direction a, and $\eta^{aa} = \eta_{aa}$ because every entry is ± 1. The constant gamma matrix of a direction carries the direction in parentheses, $\gamma^{(x4)}$; a gamma without parentheses, γ^{x4} or γ^μ, is a **curved gamma** (Section 6.2). Sums are written with $\sum$ as in Chapter 3. The one exception is the contraction $\gamma^\mu \Omega_\mu$: it always means $\sum_\mu \gamma^\mu \Omega_\mu$, and a single term is marked "(no sum)". Finally $s = \sin^{1/6} z$.

The record files. The Revision record files are named by their short names. The formula files `field-theory.json` (the metric at $b_4 = 1$) and `field-theory-b4.json` (the metric with $b_4(x_4)$) lie in the folder `Revision/theory`. The reports `python-field-theory.json` and `wolfram-field-theory.json` of the metric at $b_4 = 1$ and `python-field-theory-b4.json` and `wolfram-field-theory-b4.json` of the metric with b_4 (each pair written by a sympy program and by a WolframScript program that share no code), and the two scope reports `python-scope.json` and `wolfram-scope.json` (at $b_4 = 1$), lie in the folder `Revision/theory/reports`. The record `metric-b4.json` of the metric with b_4 lies in the folder `Revision/metric_b4/results`. The **lead report** is the file `emt-divergence-and-spin-connection.json` in the folder `Revision/lead_checks/reports`, written by an independent program of the lead of the Revision work for the metric at $b_4 = 1$.

6.2 A frame at every point: the vielbein

Why a spinor needs a frame. The gamma matrices obey the Clifford relation $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}1$ with the constant matrix η (Chapter 4). In a curved space the metric $g_{\mu\nu}(x)$ changes from point to point and is not η. The way out is to describe every point by its own eight reference directions, perpendicular to each other and of unit length (unit duration for a time-like direction). Measured in such a frame the metric looks exactly like η, so the constant gammas of Chapter 4 can be used unchanged. The spinor components are always measured with respect to such a frame.

Definition (vielbein). A **vielbein** (German for "many legs") is an 8×8 matrix $e^a{}_\mu(x)$ at every point with

$$g_{\mu\nu} = \sum_a \eta_{aa}\, e^a{}_\mu\, e^a{}_\nu \qquad \text{for all } \mu, \nu.$$

The upper index a is a **frame index**: it numbers the eight frame directions. The lower index μ is a **coordinate index**: it numbers the coordinates. Row a of the matrix holds the components of the frame direction a in the sense that a small coordinate step dx^μ has the frame components

$dX^a = \sum_\mu e^a{}_\mu dx^\mu$, and then $ds^2 = \sum_{\mu,\nu} g_{\mu\nu} dx^\mu dx^\nu = \sum_a \eta_{aa} (dX^a)^2$: lengths in frame components are computed with η. The **inverse vielbein** $e_a{}^\mu$ is the inverse matrix, $\sum_\mu e^a{}_\mu e_b{}^\mu = \delta^a_b$ (1 when $a = b$, 0 otherwise).

The diagonal vielbein of the author's metric. The author's metric is diagonal, $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$ with the positive **vielbein factors** (Chapter 3 calls them scale factors h_a; they are the same numbers)

$$f = \big(\cot z,\ e^{a_4} s,\ e^{a_4} s,\ e^{a_4} s,\ 1,\ e^{-a_4} b_4^{1/2} s,\ e^{-a_4} b_4^{1/2} s,\ e^{-a_4} b_4^{1/2} s\big), \qquad s = \sin^{1/6} z.$$

The diagonal matrix $e^a{}_\mu = f_a\, \delta^a_\mu$ is a vielbein: in the sum $\sum_a \eta_{aa} e^a{}_\mu e^a{}_\nu$ only $a = \mu = \nu$ survives, which gives $\eta_{\mu\mu} f_\mu^2 = g_{\mu\mu}$. For example, for $\mu = \nu = x1$,

$$\eta_{11} f_1^2 = (+1)\big(e^{a_4} \sin^{1/6} z\big)^2 = e^{2a_4} \sin^{1/3} z$$

(a power of a product is the product of the powers, and $(\sin^{1/6} z)^2 = \sin^{1/3} z$), which is the author's g_{11}; for $\mu = \nu = x5$, $\eta_{55} f_5^2 = (-1) e^{-2a_4} b_4 \sin^{1/3} z$ (with $(b_4^{1/2})^2 = b_4$), the author's g_{55}; for $x0$, $(+1)\cot^2 z = g_{00}$. The inverse vielbein is diagonal too, $e_a{}^\mu = \delta^\mu_a / f_a$. PROVED; `metric-b4.json`, key `metricDiagonal`; `wolfram-field-theory-b4.json`, check `metric_is_the_authors_b4`; at $b_4 = 1$ `field-theory.json`, formulas `metric` and `vielbein_diagonal`, and the lead report, check `vielbein_reproduces_metric`; Notebook 06a, In [7].

The volume factor. The determinant of a diagonal matrix is the product of its diagonal entries, so $\det g = \prod_\mu \eta_{\mu\mu} f_\mu^2 = (+1)^4 (-1)^4 \prod_\mu f_\mu^2$, and $\sqrt{|\det g|} = f_0 f_1 \cdots f_7$. Line by line:

$$f_1 f_2 f_3 = e^{3a_4} s^3, \qquad f_5 f_6 f_7 = e^{-3a_4} b_4^{3/2} s^3$$

(three equal factors; $e^{a_4} e^{a_4} e^{a_4} = e^{3a_4}$ and $(b_4^{1/2})^3 = b_4^{3/2}$),

$$f_1 f_2 f_3\, f_4\, f_5 f_6 f_7 = e^{3a_4} e^{-3a_4} b_4^{3/2} s^6 \cdot 1 = b_4^{3/2} s^6 = b_4^{3/2} \sin z$$

(the exponentials cancel, $e^u e^{-u} = 1$, and $(\sin^{1/6} z)^6 = \sin z$),

$$\sqrt{|\det g|} = b_4^{3/2} \sin z \cdot \cot z = b_4^{3/2} \sin z \cdot \frac{\cos z}{\sin z} = b_4^{3/2} \cos z$$

(multiply by $f_0 = \cot z$ and cancel $\sin z$). The volume factor depends on the time x_4 only through $b_4^{3/2}$: what 3-space gains, the extra times lose, and for a constant b_4, in particular on the backgrounds $b_4 = 1$ where it is $\cos z$, it does not depend on the time at all. PROVED; `metric-b4.json`, key `sqrtAbsDetG`; `wolfram-field-theory-b4.json`, check `sqrt_det_g`; at $b_4 = 1$ `python-field-theory.json`, check `sqrt_det_g_equals_cos_z`, and `wolfram-field-theory.json`, check `sqrt_det_g_is_cos_z`; Notebook 06a, In [7]. This one fact will explain, in Section 6.9, why the function a_4 drops out of $\gamma^\mu \Omega_\mu$ and the function b_4 does not.

Curved gammas. With the constant frame gammas γ^a define, for every coordinate μ,

$$\gamma^\mu = \sum_a e_a{}^\mu\, \gamma^a.$$

They obey the **curved Clifford relation**. Line by line:

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = \sum_{a,b} e_a{}^\mu e_b{}^\nu (\gamma^a\gamma^b + \gamma^b\gamma^a)$$

(insert the definition twice; numbers commute with matrices),

$$= \sum_{a,b} e_a{}^\mu e_b{}^\nu \, 2\eta^{ab}\, 1 = 2\sum_a \eta^{aa}\, e_a{}^\mu e_a{}^\nu \, 1 = 2g^{\mu\nu}\, 1$$

(the Clifford relation; η^{ab} is zero unless $a = b$; and $g^{\mu\nu} = \sum_a \eta^{aa} e_a{}^\mu e_a{}^\nu$ is the inverse metric, as one checks for the diagonal vielbein directly: $\eta^{\mu\mu}/f_\mu^2 = 1/g_{\mu\mu}$). For the diagonal vielbein the curved gammas are the frame gammas divided by the factors, $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (no sum):

$$\gamma^{x0} = \tan z\, \gamma^{(x0)}, \qquad \gamma^{x_i} = e^{-a_4} s^{-1} \gamma^{(x_i)}, \qquad \gamma^{x4} = \gamma^{(x4)}, \qquad \gamma^{x_t} = e^{a_4} b_4^{-1/2} s^{-1} \gamma^{(x_t)},$$

with $i = 1, 2, 3$, $t = 5, 6, 7$ and $1/\cot z = \tan z$.

A vielbein is a choice. Let $\Lambda(x)$ be an 8×8 matrix at every point with $\Lambda^T \eta \Lambda = \eta$ (an element of O(4,4), Chapter 5). Then $e'^a{}_\mu = \sum_c \Lambda^a{}_c \, e^c{}_\mu$ is another vielbein of the same metric. Line by line, in matrix form ($g = e^T \eta e$ is the definition written with matrices, e having rows a and columns μ):

$$e'^T \eta\, e' = (\Lambda e)^T \eta (\Lambda e) = e^T (\Lambda^T \eta \Lambda) e = e^T \eta\, e = g$$

(the transpose of a product is the product of the transposes in reverse order; then the defining property of Λ). Such a point-dependent turning of the frame is a **local frame rotation** (a rotation, or a boost when it mixes a space-like with a time-like direction; Chapter 5). The diagonal vielbein is the simplest choice for the author's metric, but it is one choice among infinitely many. Sections 6.15 and 6.16 show that this freedom matters.

6.3 The Christoffel symbols of the author's metric

What they are. Chapter 3 introduced the **Christoffel symbols**, the numbers that say how the coordinate directions change from point to point:

$$\Gamma^{\lambda}{}_{\mu\nu} = \tfrac{1}{2}\sum_{\rho} g^{\lambda\rho}(\partial_\mu g_{\rho\nu} + \partial_\nu g_{\rho\mu} - \partial_\rho g_{\mu\nu}).$$

They are symmetric in the two lower indices, $\Gamma^{\lambda}{}_{\mu\nu} = \Gamma^{\lambda}{}_{\nu\mu}$ (exchange μ and ν: the first two terms exchange places and the third is unchanged because g is symmetric). They enter the **coordinate covariant derivative** of a vector field, $\nabla_\mu V^\nu = \partial_\mu V^\nu + \sum_\lambda \Gamma^{\nu}{}_{\mu\lambda} V^\lambda$, the derivative that compares the vector at two points correctly although the coordinate directions change between them.

A diagonal metric. When g is diagonal, so is its inverse, $g^{\lambda\rho} = \delta^{\lambda\rho}/g_{\lambda\lambda}$, and only $\rho = \lambda$ survives in the sum. With $g_{\lambda\lambda} = \eta_{\lambda\lambda} f_\lambda^2$ there are four cases, each derived from the formula with $\rho = \lambda$ (no sums below).

(a) All three indices equal, $\lambda = \mu = \nu$:

$$\Gamma^{\lambda}{}_{\lambda\lambda} = \frac{1}{2g_{\lambda\lambda}}(\partial_\lambda g_{\lambda\lambda} + \partial_\lambda g_{\lambda\lambda} - \partial_\lambda g_{\lambda\lambda}) = \frac{\partial_\lambda g_{\lambda\lambda}}{2g_{\lambda\lambda}} = \frac{2\eta_{\lambda\lambda} f_\lambda \partial_\lambda f_\lambda}{2\eta_{\lambda\lambda} f_\lambda^2} = \partial_\lambda \ln f_\lambda$$

(two of the three terms cancel; the derivative of f^2 is $2f\,\partial f$; and $\partial f/f = \partial \ln f$).

(b) The upper index equals one lower index, $\lambda = \mu \neq \nu$:

$$\Gamma^{\lambda}{}_{\lambda\nu} = \frac{1}{2g_{\lambda\lambda}}(\partial_\lambda g_{\lambda\nu} + \partial_\nu g_{\lambda\lambda} - \partial_\lambda g_{\lambda\nu}) = \frac{\partial_\nu g_{\lambda\lambda}}{2g_{\lambda\lambda}} = \partial_\nu \ln f_\lambda$$

($g_{\lambda\nu} = 0$ for $\lambda \neq \nu$; then the same steps as in (a)).

(c) The two lower indices equal, the upper one different, $\mu = \nu \neq \lambda$:

$$\Gamma^{\lambda}{}_{\mu\mu} = \frac{1}{2g_{\lambda\lambda}}(0 + 0 - \partial_\lambda g_{\mu\mu}) = -\frac{\eta_{\mu\mu}\, 2 f_\mu \partial_\lambda f_\mu}{2\eta_{\lambda\lambda} f_\lambda^2} = -\eta_{\lambda\lambda}\eta_{\mu\mu}\,\frac{f_\mu\,\partial_\lambda f_\mu}{f_\lambda^2}$$

(the off-diagonal entries $g_{\lambda\mu}$ vanish; $1/\eta_{\lambda\lambda} = \eta_{\lambda\lambda}$ because $\eta_{\lambda\lambda} = \pm 1$).

(d) All three different: every term contains an off-diagonal entry of g, so ${\Gamma^\lambda}_{\mu\nu} = 0$.

The derivatives of the factors. The author's metric depends on x_0 (through $z = 6Hx_0$) and on x_4 (through a_4 and b_4) only, so only ∂_0 and ∂_4 of the factors can be nonzero. With $\ln f_0 = \ln\cos z - \ln\sin z$, $\ln f_i = a_4 + \frac{1}{6}\ln\sin z$ for $i = 1, 2, 3$, $\ln f_4 = 0$ and $\ln f_t = -a_4 + \frac{1}{2}\ln b_4 + \frac{1}{6}\ln\sin z$ for $t = 5, 6, 7$:

$$\partial_4 \ln f_i = a_4' = \alpha, \qquad \partial_4 \ln f_t = -a_4' + \frac{b_4'}{2b_4} = \alpha_t, \qquad \partial_4 \ln f_0 = 0$$

(only $\pm a_4$ and $\frac{1}{2}\ln b_4$ depend on x_4; their derivatives are $\pm a_4'$ and $\frac{1}{2}b_4'/b_4$),

$$\partial_0 \ln f_i = \partial_0 \ln f_t = \frac{1}{6} \cdot \frac{\cos z}{\sin z} \cdot 6H = H \cot z$$

(the chain rule: the derivative of $\ln\sin z$ with respect to z is $\cos z/\sin z$, and $dz/dx_0 = 6H$),

$$\partial_0 \ln f_0 = 6H\Big(\frac{-\sin z}{\cos z} - \frac{\cos z}{\sin z}\Big) = -6H\,\frac{\sin^2 z + \cos^2 z}{\sin z\cos z} = -\frac{6H}{\sin z\cos z}$$

(the chain rule again; common denominator; $\sin^2 z + \cos^2 z = 1$).

The 25 symbols. Insert these into the four cases. With $\lambda = x0$, case (a): ${\Gamma^{x0}}_{x0\,x0} = -6H/(\sin z\cos z) = -12H/\sin 2z$ (the double-angle formula $\sin 2z = 2\sin z\cos z$). From (a) and (b) with $\lambda = x_i$ and $\lambda = x_t$:

$${\Gamma^{x_i}}_{x_i\,x4} = a_4', \qquad {\Gamma^{x_t}}_{x_t\,x4} = -a_4' + \frac{b_4'}{2b_4} = \alpha_t, \qquad {\Gamma^{x_i}}_{x_i\,x0} = {\Gamma^{x_t}}_{x_t\,x0} = H\cot z.$$

From (c) with $\lambda = x4$ ($\eta_{44} = -1$, $f_4 = 1$):

$$\Gamma^{x4}{}_{x_i\,x_i} = -(-1)(+1) f_i\,\partial_4 f_i = f_i^2\,a_4' = e^{2a_4}\sin^{1/3} z\; a_4',$$

$$\Gamma^{x4}{}_{x_t\,x_t} = -(-1)(-1) f_t\,\partial_4 f_t = -f_t^2\,\alpha_t = e^{-2a_4} b_4 \sin^{1/3} z\,\Big(a_4' - \frac{b_4'}{2b_4}\Big)$$

(for the extra times $\partial_4 f_t = \alpha_t f_t$). From (c) with $\lambda = x0$ ($\eta_{00} = +1$, $f_0 = \cot z$):

$${\Gamma^{x0}}_{x_i\,x_i} = -\frac{f_i\,\partial_0 f_i}{\cot^2 z} = -\frac{f_i^2 H\cot z}{\cot^2 z} = -f_i^2 H\tan z, \qquad {\Gamma^{x0}}_{x_t\,x_t} = +f_t^2 H\tan z$$

($\partial_0 f_i = f_i H\cot z$; $\eta_{tt} = -1$ reverses the sign for the extra times). Every other symbol vanishes: f_0 and $f_4 = 1$ do not depend on x_4, and the factors depend on no other coordinate. Counting with $\mu \le \nu$: one ${\Gamma^{x0}}_{x0x0}$, and three each of the eight families ${\Gamma^{x_i}}_{x0x_i}$, ${\Gamma^{x_i}}_{x_ix4}$, ${\Gamma^{x_t}}_{x0x_t}$, ${\Gamma^{x_t}}_{x4x_t}$, ${\Gamma^{x0}}_{x_ix_i}$, ${\Gamma^{x4}}_{x_ix_i}$, ${\Gamma^{x0}}_{x_tx_t}$, ${\Gamma^{x4}}_{x_tx_t}$: $1 + 8\cdot 3 = 25$, the same number as for $b_4 = 1$. Every nonzero symbol carries an index $x0$ or $x4$. In words: moving forward in time a 3-space direction grows at the rate

a_4' (${\Gamma^{x1}}_{x1x4} = a_4'$) and an extra-time direction grows at the rate α_t (${\Gamma^{x5}}_{x4x5} = -a_4' + b_4'/(2b_4)$): for a constant b_4 it shrinks at the same rate a_4'.

6.4 The canonical spin connection: the vielbein postulate and its solution

The problem. A vector field V has the coordinate components V^ν and the frame components $V^a = \sum_\nu e^a{}_\nu V^\nu$. The frame turns from point to point, so $\partial_\mu V^a$ mixes the change of V with the turning of the frame, just as $\partial_\mu V^\nu$ mixed the change of V with the bending of the coordinate lines. The cure is the same: a correction that is linear in V,

$$\nabla_\mu V^a = \partial_\mu V^a + \sum_b \omega_\mu{}^a{}_b \, V^b,$$

with coefficients $\omega_\mu{}^a{}_b(x)$, the **spin connection**. It has one coordinate index μ (the direction of the step) and two frame indices a, b (which frame direction turns towards which).

The requirement. The frame components of the covariant derivative must be the covariant derivative of the frame components: $\sum_\nu e^a{}_\nu \, \nabla_\mu V^\nu = \nabla_\mu V^a$ for every vector field V. Write both sides out. The left side is

$$\sum_\nu e^a{}_\nu \Big(\partial_\mu V^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda} V^\lambda \Big).$$

The right side is

$$\partial_\mu \Big(\sum_\lambda e^a{}_\lambda V^\lambda \Big) + \sum_b \omega_\mu{}^a{}_b \sum_\lambda e^b{}_\lambda V^\lambda = \sum_\lambda (\partial_\mu e^a{}_\lambda) V^\lambda + \sum_\lambda e^a{}_\lambda \, \partial_\mu V^\lambda + \sum_{b,\lambda} \omega_\mu{}^a{}_b \, e^b{}_\lambda V^\lambda$$

(the definition of V^a and V^b; then the product rule). The terms with $\partial_\mu V$ are the same on both sides (rename ν as λ). Subtracting the left side from the right side leaves

$$\sum_{\lambda}\Big(\partial_\mu e^{a}{}_{\lambda}-\sum_{\nu}\Gamma^{\nu}{}_{\mu\lambda}e^{a}{}_{\nu}+\sum_{b}\omega_{\mu}{}^{a}{}_{b}\,e^{b}{}_{\lambda}\Big)V^{\lambda}=0$$

(collect the coefficient of each V^λ). This must hold for every V, so every bracket vanishes. Renaming λ as ν and the summed ν as λ, this is the **vielbein postulate**:

$$\partial_\mu e^{a}{}_{\nu}-\sum_{\lambda}\Gamma^{\lambda}{}_{\mu\nu}\,e^{a}{}_{\lambda}+\sum_{b}\omega_{\mu}{}^{a}{}_{b}\,e^{b}{}_{\nu}=0\qquad\text{for all }\mu,a,\nu.$$

In eight dimensions these are $8\cdot 8\cdot 8=512$ equations.

The solution. Multiply the postulate by $e_c{}^{\nu}$ and sum over ν. The last term becomes $\sum_b \omega_\mu{}^a{}_b \sum_\nu e^b{}_\nu e_c{}^\nu = \sum_b \omega_\mu{}^a{}_b \delta^b_c = \omega_\mu{}^a{}_c$ (the inverse vielbein), so

$$\omega_{\mu}{}^{a}{}_{c}=\sum_{\nu,\lambda}e_c{}^{\nu}\,\Gamma^{\lambda}{}_{\mu\nu}\,e^{a}{}_{\lambda}-\sum_{\nu}e_c{}^{\nu}\,\partial_\mu e^{a}{}_{\nu}.$$

Differentiate $\sum_\nu e^a{}_\nu e_c{}^\nu = \delta^a_c$ (a constant) with the product rule: $\sum_\nu e_c{}^\nu \partial_\mu e^a{}_\nu = -\sum_\nu e^a{}_\nu \partial_\mu e_c{}^\nu$. Inserting this and renaming the summation letters gives the formula that the Revision record and all three notebooks use:

$$\omega_{\mu}{}^{a}{}_{b}=\sum_{\nu}e^{a}{}_{\nu}\Big(\partial_\mu e_b{}^{\nu}+\sum_{\lambda}\Gamma^{\nu}{}_{\mu\lambda}\,e_b{}^{\lambda}\Big).$$

The derivation shows that the postulate has this one solution and no other: it is the **canonical spin connection**. Its components $\omega_\mu{}^a{}_b$, with the first frame index up, are called the **mixed components**.

Lowering the first index. Define $\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b$ (no sum). **Theorem: $\omega_{\mu ab} = -\omega_{\mu ba}$.** Proof, line by line. First, $\eta_{aa}e^a{}_\nu = \sum_\sigma g_{\nu\sigma}e_a{}^\sigma$: multiply $g_{\nu\sigma} = \sum_c \eta_{cc}e^c{}_\nu e^c{}_\sigma$ by $e_a{}^\sigma$ and sum over σ; only $c=a$ survives. So

$$\omega_{\mu ab}=\sum_{\nu,\sigma}g_{\nu\sigma}\,e_a{}^{\sigma}\,\partial_\mu e_b{}^{\nu}+\sum_{\sigma,\lambda}e_a{}^{\sigma}\,\Gamma_{\sigma\mu\lambda}\,e_b{}^{\lambda},\qquad\Gamma_{\sigma\mu\lambda}=\sum_{\nu}g_{\sigma\nu}\Gamma^{\nu}{}_{\mu\lambda}$$

(insert into the formula; $\Gamma_{\sigma\mu\lambda}$ is the Christoffel symbol with its first index lowered, $\frac{1}{2}(\partial_\mu g_{\sigma\lambda}+\partial_\lambda g_{\sigma\mu}-\partial_\sigma g_{\mu\lambda})$). Second, adding the two lowered symbols with the outer indices exchanged,

$$\Gamma_{\sigma\mu\lambda}+\Gamma_{\lambda\mu\sigma}=\tfrac{1}{2}(\partial_\mu g_{\sigma\lambda}+\partial_\lambda g_{\sigma\mu}-\partial_\sigma g_{\mu\lambda}+\partial_\mu g_{\lambda\sigma}+\partial_\sigma g_{\lambda\mu}-\partial_\lambda g_{\mu\sigma})=\partial_\mu g_{\sigma\lambda}$$

(g is symmetric, so the second and sixth terms cancel, the third and fifth cancel, and the first and fourth are equal). Third, add $\omega_{\mu ab}$ and $\omega_{\mu ba}$:

$$\omega_{\mu ab}+\omega_{\mu ba}=\sum_{\nu,\sigma}g_{\nu\sigma}(e_a{}^{\sigma}\partial_\mu e_b{}^{\nu}+e_b{}^{\sigma}\partial_\mu e_a{}^{\nu})+\sum_{\sigma,\lambda}e_a{}^{\sigma}e_b{}^{\lambda}\,\partial_\mu g_{\sigma\lambda}=\partial_\mu\Big(\sum_{\sigma,\lambda}g_{\sigma\lambda}e_a{}^{\sigma}e_b{}^{\lambda}\Big)$$

(the second step: in the second Γ term rename $\sigma \leftrightarrow \lambda$ and use the identity just shown; then the three terms are the three pieces of the product rule for $g\, e_a\, e_b$). Finally $\sum_{\sigma,\lambda} g_{\sigma\lambda} e_a{}^{\sigma} e_b{}^{\lambda} = \eta_{ab}$ (the frame directions are perpendicular and of unit length), a constant, whose derivative is zero. $\square$

So for each μ the lowered connection is an antisymmetric 8×8 array: its diagonal vanishes and it has $8 \cdot 7/2 = 28$ independent entries, one for each of the 28 generators S^{ab} of Chapter 5. In words: $\omega_{\mu ab}$ is the rate at which the frame turns in the plane (a, b) when one moves along x^{μ}. The mixed components are not antisymmetric in general: $\omega_{\mu}{}^{b}{}_{a} = \eta_{bb}\omega_{\mu ba} = -\eta_{bb}\omega_{\mu ab} = -\eta_{aa}\eta_{bb}\,\omega_{\mu}{}^{a}{}_{b}$, which is antisymmetric for a pair of two space-like or two time-like directions and **symmetric** for a boost pair (Section 6.23 returns to this).

6.5 A warm-up by hand: the flat plane in polar coordinates

Before eight dimensions, two. A point of the flat plane has the polar coordinates r (distance from the centre) and φ (angle). The metric is $ds^2 = dr^2 + r^2 d\varphi^2$ (Chapter 3), so $g = \mathrm{diag}(1, r^2)$, $\eta = \mathrm{diag}(1, 1)$, and the factors are $f_r = 1$, $f_\varphi = r$: the unit radial direction (frame index 0) and the unit angular direction (frame index 1).

Christoffel symbols. Case (c) of Section 6.3 with $\lambda = r$, $\mu = \varphi$: $\Gamma^{r}{}_{\varphi\varphi} = -(1)(1)\, f_\varphi \partial_r f_\varphi / f_r^2 = -r \cdot 1 = -r$. Case (b): $\Gamma^{\varphi}{}_{\varphi r} = \partial_r \ln r = 1/r$. All others vanish.

Spin connection. The formula of Section 6.4 with $\mu = \varphi$, $a = 1$ (angular), $b = 0$ (radial), where $e^{1}{}_{\varphi} = r$ and $e_0{}^{r} = 1$ are the only entries needed:

$$\omega_{\varphi}{}^{1}{}_{0} = e^{1}{}_{\varphi}\big(\partial_\varphi e_0{}^{\varphi} + \Gamma^{\varphi}{}_{\varphi r} e_0{}^{r}\big) = r\Big(0 + \frac{1}{r} \cdot 1\Big) = 1$$

(only $\nu = \varphi$ has $e^{1}{}_{\nu} \neq 0$; $e_0{}^{\varphi} = 0$; only $\lambda = r$ has $e_0{}^{\lambda} \neq 0$). With $\eta = \mathrm{diag}(1, 1)$ lowering changes nothing: $\omega_{\varphi 10} = 1$ and, by the antisymmetry, $\omega_{\varphi 01} = -1$. For $\mu = r$ everything vanishes. **Meaning:** the radial and angular unit directions at the angle φ are the Cartesian ones turned by the angle φ; moving in φ turns the frame at one radian per radian, and the spin connection records this rate.

Spinor connection. Two 2×2 matrices with the Clifford relation of the plane are the Pauli matrices

$\gamma^0 = \sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $\gamma^1 = \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$, with $\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$; one checks by multiplying out that $\sigma_1\sigma_2 = i\sigma_3$ and $\sigma_2\sigma_3 = i\sigma_1$. The generator of the plane is $S^{01} = \frac{1}{4}[\sigma_1, \sigma_2] = \frac{1}{2}\sigma_1\sigma_2 = \frac{i}{2}\sigma_3$. Section 6.7 will show that the spinor connection is $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$, so

$$\Omega_\varphi = \omega_{\varphi 01} S^{01} = -\tfrac{i}{2}\,\sigma_3, \qquad \Omega_r = 0.$$

The contraction. The curved gammas are $\gamma^r = \sigma_1$ and $\gamma^\varphi = \sigma_2/r$, so

$$\sum_\mu \gamma^\mu \Omega_\mu = \frac{\sigma_2}{r}\Big(-\frac{i}{2}\sigma_3\Big) = -\frac{i}{2r}\,\sigma_2\sigma_3 = -\frac{i}{2r}\,i\sigma_1 = \frac{\sigma_1}{2r}$$

($i \cdot i = -1$). The Dirac operator of the flat plane in polar coordinates is therefore $\sigma_1(\partial_r + \frac{1}{2r}) + \frac{\sigma_2}{r}\partial_\varphi$: a term without derivative appears although the plane is flat.

But the plane is flat, and the connection can be removed. The **curvature of the spinor connection** is $F_{r\varphi} = \partial_r\Omega_\varphi - \partial_\varphi\Omega_r + \Omega_r\Omega_\varphi - \Omega_\varphi\Omega_r$; here Ω_φ is constant and $\Omega_r = 0$, so every term vanishes: $F_{r\varphi} = 0$. And with the spinor rotation $U(\varphi) = \cos\frac{\varphi}{2} + i\sin\frac{\varphi}{2}\,\sigma_3$ (Chapter 5: a rotation by the angle φ acts on spinors through the half angle),

$$\partial_\varphi U = -\tfrac{1}{2}\sin\tfrac{\varphi}{2} + \tfrac{i}{2}\cos\tfrac{\varphi}{2}\,\sigma_3 = \tfrac{i}{2}\sigma_3\Big(\cos\tfrac{\varphi}{2} + i\sin\tfrac{\varphi}{2}\,\sigma_3\Big) = \tfrac{i}{2}\sigma_3\,U$$

(differentiate each entry; then factor out $\frac{i}{2}\sigma_3$, using $\sigma_3\sigma_3 = 1$ and $i \cdot i = -1$), so $-(\partial_\varphi U)U^{-1} = -\frac{i}{2}\sigma_3 = \Omega_\varphi$.

Which rotation removes it. Section 6.15 will derive how the spinor connection changes when the frame is changed and the spinor components change by a spin transformation R: $\Omega'_\varphi = R\,\Omega_\varphi R^{-1} - (\partial_\varphi R)R^{-1}$. The Cartesian frame (the unit directions along x and y) does not turn, so its connection is 0, and the rule with $R = U$ turns this 0 into $-(\partial_\varphi U)U^{-1} = \Omega_\varphi$: U is the spinor rotation that carries the Cartesian frame into the polar frame. The way back is the inverse rotation $U^{-1} = \cos\frac{\varphi}{2} - i\sin\frac{\varphi}{2}\,\sigma_3$ (multiply out: $UU^{-1} = \cos^2\frac{\varphi}{2} + \sin^2\frac{\varphi}{2}\,\sigma_3\sigma_3 = 1$, because the two mixed terms cancel). Its derivative is

$$\partial_\varphi U^{-1} = -\tfrac{1}{2}\sin\tfrac{\varphi}{2} - \tfrac{i}{2}\cos\tfrac{\varphi}{2}\,\sigma_3 = -\tfrac{i}{2}\sigma_3\Big(\cos\tfrac{\varphi}{2} - i\sin\tfrac{\varphi}{2}\,\sigma_3\Big) = -\tfrac{i}{2}\sigma_3\,U^{-1}$$

(differentiate each entry; then factor out $-\frac{i}{2}\sigma_3$, using $\sigma_3\sigma_3 = 1$ and $i \cdot i = -1$), so $(\partial_\varphi U^{-1})\,U = -\frac{i}{2}\sigma_3$. The matrix σ_3 commutes with U and U^{-1} (both are built from 1 and σ_3), so $U^{-1}\Omega_\varphi U = \Omega_\varphi U^{-1}U = \Omega_\varphi$. The rule with $R = U^{-1}$ (whose inverse is U) therefore gives

$$\Omega'_\varphi = U^{-1}\,\Omega_\varphi\,U - (\partial_\varphi U^{-1})\,U = -\tfrac{i}{2}\sigma_3 - \Big(-\tfrac{i}{2}\sigma_3\Big) = 0,$$

and $\Omega'_r = 0$, because U does not depend on r. (The rule with $R = U$ would instead give $-\frac{i}{2}\sigma_3 - \frac{i}{2}\sigma_3 = -i\sigma_3$: the rotation U turns the polar frame further, not back.) In a flat space the spin connection is only the turning of the chosen frame, and the spinor rotation U^{-1} removes it. At $\varphi = 2\pi$ the frame is back where it started, but $U(2\pi) = \cos\pi = -1$: a spinor turns by half the

angle, the double cover of Chapter 5. Notebook 06a checks all of this in In [5] and draws it in figure 1. PROVED (exact; the notebook's checks are its own, the plane is not a Revision record).

Two lessons. First, a nonzero spin connection, and even a nonzero $\sum_\mu \gamma^\mu \Omega_\mu$, does not mean that space is curved; it may only record how the chosen frame turns. Second, the test of curvature is $F_{\mu\nu}$, not Ω_μ. Both lessons return in Sections 6.16 and 6.17.

6.6 The spin connection of the author's metric: twelve components

A diagonal vielbein, in general. Let $e^a{}_\mu = f_a \delta^a_\mu$ and $e_b{}^\nu = \delta^\nu_b / f_b$. In the formula of Section 6.4 only $\nu = a$ survives in the outer sum and only $\lambda = b$ in the inner sum:

$$\omega_\mu{}^a{}_b = f_a \Big(\partial_\mu \frac{\delta^a_b}{f_b} + \Gamma^a{}_{\mu b} \frac{1}{f_b} \Big).$$

For $a = b$ this is $f_a \big(- \partial_\mu f_a / f_a^2 + \Gamma^a{}_{\mu a} / f_a \big) = \Gamma^a{}_{\mu a} - \partial_\mu \ln f_a = 0$, by cases (a) and (b) of Section 6.3. For $a \neq b$ only the second term remains, $(f_a/f_b)\Gamma^a{}_{\mu b}$, and by case (d) it can be nonzero only when $\mu = a$ or $\mu = b$:

$$\omega_a{}^a{}_b = \frac{f_a}{f_b}\, \partial_b \ln f_a = \frac{\partial_b f_a}{f_b}, \qquad \omega_b{}^a{}_b = \frac{f_a}{f_b} \Big(- \eta_{aa}\eta_{bb} \frac{f_b\, \partial_a f_b}{f_a^2} \Big) = -\eta_{aa}\eta_{bb}\, \frac{\partial_a f_b}{f_a}$$

(no sums; case (b) with $\lambda = a$, $\nu = b$, and case (c) with $\lambda = a$, $\mu = b$). Lowering with η_{aa} gives the two forms

$$\omega_{a\,ab} = \eta_{aa}\, \frac{\partial_b f_a}{f_b}, \qquad \omega_{b\,ab} = -\eta_{bb}\, \frac{\partial_a f_b}{f_a} \qquad (a \neq b, \text{ no sum}),$$

and the antisymmetry of Section 6.4 can be seen directly: the second form with the letters a and b exchanged reads $\omega_{a\,ba} = -\eta_{aa} \partial_b f_a / f_b = -\omega_{a\,ab}$. So: **in a diagonal vielbein, $\omega_{\mu ab}$ is nonzero only when μ is one of the two frame indices, and then $\omega_{\mu\,\mu b} = \eta_{\mu\mu}\, \partial_b f_\mu / f_b$.**

The author's metric. The factors depend on x_0 and x_4 only, so b must be $x0$ or $x4$. With $\partial_4 f_i = a_4' f_i$, $\partial_4 f_t = \alpha_t f_t$, $\partial_0 f_i = H \cot z\, f_i$, $\partial_0 f_t = H \cot z\, f_t$ (Section 6.3), $f_0 = \cot z$ and $f_4 = 1$:

$$\omega_{x_i\, x_i\, x4} = (+1) \frac{a_4' f_i}{1} = a_4'\, e^{a_4} s, \qquad \omega_{x_i\, x_i\, x0} = (+1) \frac{H \cot z\, f_i}{\cot z} = H\, e^{a_4} s,$$

$$\omega_{x_t\, x_t\, x4} = (-1) \frac{\alpha_t f_t}{1} = \Big(a_4' - \frac{b_4'}{2 b_4} \Big) e^{-a_4} b_4^{1/2} s, \qquad \omega_{x_t\, x_t\, x0} = (-1) \frac{H \cot z\, f_t}{\cot z} = -H\, e^{-a_4} b_4^{1/2} s.$$

The record lists the components with the smaller index first, $a < b$ in the order $x0, \ldots, x7$; for 3-space this is $\omega_{x_i\, x0\, x_i} = -\omega_{x_i\, x_i\, x0} = -H\, e^{a_4} s$, and for the extra times $\omega_{x_t\, x4\, x_t} = -\omega_{x_t\, x_t\, x4}$ and $\omega_{x_t\, x0\, x_t} = -\omega_{x_t\, x_t\, x0}$. For $\mu = x4$ every candidate contains $\partial_b f_4 = 0$ (because $f_4 = 1$), and for $\mu = x0$ the only candidate, $b = x4$, contains $\partial_4 f_0 = 0$ (because $\cot z$ does not depend on the time); so $\omega_{x0\,ab} = \omega_{x4\,ab} = 0$. Altogether there are $3 \cdot 2 + 3 \cdot 2 = 12$ independent nonzero components:

μ	**pair** (a,b)	$\omega_{\mu ab}$	**kind of pair**
x_i $(i=1,2,3)$	$(x0,x_i)$	$-H\,e^{a_4}s$	rotation (two space-like)
x_i	$(x_i,x4)$	$a_4'\,e^{a_4}s$	boost (space-like with time-like)
x_t $(t=5,6,7)$	$(x0,x_t)$	$H\,e^{-a_4}b_4^{1/2}s$	boost (space-like with time-like)
x_t	$(x4,x_t)$	$-\big(a_4'-\frac{b_4'}{2b_4}\big)e^{-a_4}b_4^{1/2}s$	rotation (two time-like)

Each component is a rate times a factor that never vanishes for $0<z<\pi/2$: the rate is a_4' (3-space), $a_4'-b_4'/(2b_4)=-\alpha_t$ (the extra times) or H (the hidden direction), the factor $\pm e^{a_4}\sin^{1/6}z$ or $\pm e^{-a_4}b_4^{1/2}\sin^{1/6}z$. So the part made by the time dependence (3-space inflating, the extra times deflating) vanishes only if a_4 and b_4 are constant, and the part made by the hidden direction vanishes only if $H=0$, which is not a metric of the family (the entries $\sin^{1/3}(6Hx_0)$ would vanish; record check `degenerate_at_H_0`). **For every admissible $H>0$ the spin connection of the diagonal vielbein is nonzero.** Note also the signs: the extra time $x5$ has the opposite signs of the 3-space direction $x1$, because it shrinks while 3-space grows (for a constant b_4 at the same rate). Figure 06a.4 shows the arrays $\omega_{x1\,ab}$ and $\omega_{x5\,ab}$ at a sample point.

6.7 The spinor connection and the covariant derivative of a spinor

What we want. A spinor Ψ has no coordinate index; its sixteen components are measured in the frame. Its covariant derivative must be of the form

$$D_\mu\Psi=\partial_\mu\Psi+\Omega_\mu\Psi$$

with eight 16×16 matrices $\Omega_\mu(x)$, the **spinor connection**. Which matrices? The gamma matrices link spinors and vectors: $\gamma^\nu\Psi$ is again a spinor, but γ^ν carries the vector index ν. The natural requirement is that the derivative treats the curved gammas as constants, as the flat derivative treats the constant gammas:

$$D_\mu\gamma^\nu = \partial_\mu\gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0,$$

where $[A, B] = AB - BA$ is the **commutator**. The first two terms are the coordinate covariant derivative of the vector index of γ^ν, the commutator is the spinor connection acting on the matrix from the left and from the right. With this requirement the product rule holds in the form $D_\mu(\gamma^\nu\Psi) = \gamma^\nu D_\mu\Psi$, so the field equation $\sum_\mu \gamma^\mu D_\mu\Psi = (m + U')\Psi$ does not depend on where the derivative is written.

The requirement in frame form. Insert $\gamma^\nu = \sum_a e_a{}^\nu\gamma^a$ (the frame gammas are constant):

$$D_\mu\gamma^\nu = \sum_a \Big(\partial_\mu e_a{}^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda} e_a{}^\lambda\Big)\gamma^a + \sum_a e_a{}^\nu [\Omega_\mu, \gamma^a]$$

(the product rule; numbers commute with matrices). Multiply the formula of Section 6.4 by $e_c{}^\sigma$ and sum over c: since $\sum_c e_c{}^\sigma e^c{}_\nu = \delta^\sigma_\nu$, this gives $\partial_\mu e_b{}^\sigma + \sum_\lambda \Gamma^\sigma{}_{\mu\lambda} e_b{}^\lambda = \sum_c e_c{}^\sigma\, \omega_\mu{}^c{}_b$. With it the first sum becomes $\sum_{a,c} e_c{}^\nu \omega_\mu{}^c{}_a \gamma^a$, and

$$D_\mu\gamma^\nu = \sum_c e_c{}^\nu \Big([\Omega_\mu, \gamma^c] + \sum_a \omega_\mu{}^c{}_a \gamma^a\Big)$$

(rename a as c in the second sum). The inverse vielbein is invertible, so $D_\mu\gamma^\nu = 0$ for all ν holds exactly when

$$[\Omega_\mu, \gamma^c] = -\sum_b \omega_\mu{}^c{}_b\, \gamma^b \qquad \text{for all } \mu, c.$$

This is the **defining property** of the spinor connection: commuting with Ω_μ turns the gammas exactly as ω_μ turns the frame.

The solution. Theorem. $\Omega_\mu = \frac{1}{2}\sum_{a,b} \omega_{\mu ab} S^{ab}$, with the generators $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b]$ of Chapter 5, has the defining property. Proof, line by line. Chapter 5 proved the **vector rule** $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b$. So

$$[\Omega_\mu, \gamma^c] = \tfrac{1}{2}\sum_{a,b} \omega_{\mu ab}(\eta^{bc}\gamma^a - \eta^{ac}\gamma^b) = \tfrac{1}{2}\,\eta^{cc}\sum_a \omega_{\mu ac}\gamma^a - \tfrac{1}{2}\,\eta^{cc}\sum_b \omega_{\mu cb}\gamma^b$$

(a commutator is linear in each argument; η^{bc} is nonzero only for $b = c$, η^{ac} only for $a = c$). By the antisymmetry $\omega_{\mu ac} = -\omega_{\mu ca}$ the first sum is $-\frac{1}{2}\eta^{cc}\sum_a \omega_{\mu ca}\gamma^a$, the same as the second (rename a as b). Hence

$$[\Omega_\mu, \gamma^c] = -\eta^{cc}\sum_b \omega_{\mu cb}\gamma^b = -\sum_b \omega_\mu{}^c{}_b \gamma^b$$

(two equal halves; and $\eta^{cc}\omega_{\mu cb} = \eta_{cc}\eta_{cc}\omega_\mu{}^c{}_b = \omega_\mu{}^c{}_b$ because $\eta_{cc}^2 = 1$). $\square$

Uniqueness. If Ω'_μ also had the defining property, the difference $\Omega'_\mu - \Omega_\mu$ would commute with all eight gammas, and Chapter 5 proved that only multiples of the identity do (the commutant of Pin(4,4) is one-dimensional). Every S^{ab} has trace 0 (it is a multiple of a commutator, and $\mathrm{tr}(AB) = \mathrm{tr}(BA)$), so Ω_μ is the only solution with trace 0. A multiple of the identity would be an extra field of the electromagnetic kind, not part of gravity; the canonical connection has none.

Summing over $a < b$. Both $\omega_{\mu ab}$ and S^{ab} change sign when a and b are exchanged, so the terms (a, b) and (b, a) are equal, the terms $a = b$ vanish, and

$$\Omega_\mu = \tfrac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab} = \sum_{a<b}\omega_{\mu ab}S^{ab}, \qquad S^{ab} = \tfrac{1}{2}\gamma^a\gamma^b \ (a \neq b)$$

(for $a \neq b$ the two gammas anticommute, so $\gamma^a\gamma^b - \gamma^b\gamma^a = 2\gamma^a\gamma^b$).

The derivative of the Dirac adjoint. The Dirac adjoint is $\bar\Psi = \Psi^\dagger C$ (Chapter 5), and its covariant derivative is $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\,\Omega_\mu$; with this sign the number $\bar\Psi\Phi$ obeys the ordinary product rule, $(D_\mu\bar\Psi)\Phi + \bar\Psi D_\mu\Phi = \partial_\mu(\bar\Psi\Phi)$, because the two Ω_μ terms cancel. It agrees with the conjugate of $D_\mu\Psi$: Ω_μ is real and Chapter 5 proved $(S^{ab})^T C = -CS^{ab}$, so $(D_\mu\Psi)^\dagger C = \partial_\mu\Psi^\dagger C + \Psi^\dagger\Omega_\mu^T C = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$.

The author's metric. With the table of Section 6.6 and $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$:

$$\begin{aligned}\Omega_{x_i} &= e^{a_4}s\big(a'_4\,S^{x_i\,x4} + H\,S^{x_i\,x0}\big), \qquad \Omega_{x0} = \Omega_{x4} = 0,\\ \Omega_{x_t} &= -e^{-a_4}b_4^{1/2}s\Big(\big(a'_4 - \tfrac{b'_4}{2b_4}\big)S^{x4\,x_t} + H\,S^{x_t\,x0}\Big)\end{aligned}$$

(with $S^{x_i\,x0} = -S^{x0\,x_i}$ and $S^{x_t\,x0} = -S^{x0\,x_t}$, the components of the table).

No frame direction turns when one moves along the time or along the hidden direction. Each nonzero Ω_μ is a combination of two generators. A boost generator is a **symmetric** matrix and a rotation generator an **antisymmetric** one: the transpose of a product reverses the order, and the author's gammas satisfy $(\gamma^a)^T = \eta_{aa}\gamma^a$ (Chapter 5), so

$$(\gamma^a\gamma^b)^T = (\gamma^b)^T(\gamma^a)^T = \eta_{aa}\eta_{bb}\,\gamma^b\gamma^a = -\eta_{aa}\eta_{bb}\,\gamma^a\gamma^b \qquad (a \neq b),$$

which is $+\gamma^a\gamma^b$ for a boost pair ($\eta_{aa}\eta_{bb} = -1$, 16 pairs) and $-\gamma^a\gamma^b$ for a rotation pair (12 pairs). In Ω_{x1} the a'_4 part is a boost ($x1$ with $x4$) and the H part a rotation ($x1$ with $x0$); in Ω_{x5} it is the other way round. Figure 06a.5 shows both matrices.

The covariant constancy, checked. With these Ω_μ the defining property holds for all 64 pairs (μ, c) and $D_\mu\gamma^\nu = 0$ for all 64 pairs (μ, ν) (Notebook 06a, In [13]).

6.8 The contraction $\gamma^\mu \Omega_\mu$, direction by direction

The field equation contains $\sum_\mu \gamma^\mu D_\mu \Psi = \sum_\mu \gamma^\mu \partial_\mu \Psi + \big(\sum_\mu \gamma^\mu \Omega_\mu\big)\Psi$, so the spin connection enters it only through the one 16×16 matrix $\sum_\mu \gamma^\mu \Omega_\mu$. We compute it one direction at a time.

A 3-space direction, $\mu = x1$ (the same for $x2$ and $x3$). With $\gamma^{x1} = \gamma^{(x1)}/f_1$ and $f_1 = e^{a_4} s$:

$$\gamma^{x1}\Omega_{x1} = \frac{\gamma^{(x1)}}{f_1}\, f_1 \Big(a_4' \tfrac{1}{2}\gamma^{(x1)}\gamma^{(x4)} + H\, \tfrac{1}{2}\gamma^{(x1)}\gamma^{(x0)} \Big)$$

(the formulas of Sections 6.2 and 6.7),

$$= \tfrac{1}{2} a_4' \, \gamma^{(x1)}\gamma^{(x1)}\gamma^{(x4)} + \tfrac{1}{2} H \, \gamma^{(x1)}\gamma^{(x1)}\gamma^{(x0)} = \tfrac{1}{2} a_4' \, \gamma^{(x4)} + \tfrac{1}{2} H \, \gamma^{(x0)}$$

(the factor f_1 cancels; $\gamma^{(x1)}\gamma^{(x1)} = \eta_{11} 1 = +1$ by the Clifford relation).

An extra time, $\mu = x5$ (the same for $x6$ and $x7$). With $\gamma^{x5} = \gamma^{(x5)}/f_5$ and the rate $r = a_4' - b_4'/(2b_4) = -\alpha_t$:

$$\gamma^{x5}\Omega_{x5} = \frac{\gamma^{(x5)}}{f_5}\,(-f_5)\Big(r\,\tfrac{1}{2}\gamma^{(x4)}\gamma^{(x5)} + H\,\tfrac{1}{2}\gamma^{(x5)}\gamma^{(x0)}\Big) = -\tfrac{1}{2}r\,\gamma^{(x5)}\gamma^{(x4)}\gamma^{(x5)} - \tfrac{1}{2}H\,\gamma^{(x5)}\gamma^{(x5)}\gamma^{(x0)}$$

(the factor $f_5 = e^{-a_4}b_4^{1/2}s$ cancels and leaves the sign). Now $\gamma^{(x5)}\gamma^{(x4)}\gamma^{(x5)} = -\gamma^{(x4)}\gamma^{(x5)}\gamma^{(x5)} = -\gamma^{(x4)}(-1) = \gamma^{(x4)}$ (two different gammas anticommute; $\gamma^{(x5)}\gamma^{(x5)} = \eta_{55}1 = -1$), and $\gamma^{(x5)}\gamma^{(x5)}\gamma^{(x0)} = -\gamma^{(x0)}$. Hence

$$\gamma^{x5}\Omega_{x5} = -\tfrac{1}{2}\Big(a_4' - \frac{b_4'}{2b_4}\Big)\gamma^{(x4)} + \tfrac{1}{2}H\,\gamma^{(x0)} = \Big(-\tfrac{1}{2}a_4' + \frac{b_4'}{4b_4}\Big)\gamma^{(x4)} + \tfrac{1}{2}H\,\gamma^{(x0)}.$$

The hidden direction and the time. $\Omega_{x0} = \Omega_{x4} = 0$, so $\gamma^{x0}\Omega_{x0} = \gamma^{x4}\Omega_{x4} = 0$.

The sum. Writing each term as $\alpha_\mu\gamma^{(x4)} + \beta_\mu\gamma^{(x0)}$ (these coefficients α_μ are not the expansion rates α, α_t of Section 6.3):

direction μ	α_μ **(coefficient of $\gamma^{(x4)}$)**	β_μ **(coefficient of $\gamma^{(x0)}$)**
$x0$ (hidden)	0	0
$x1$, $x2$, $x3$ (inflating)	$+\frac{1}{2}a_4'$ each	$\frac{1}{2}H$ each
$x4$ (time)	0	0
$x5$, $x6$, $x7$ (deflating)	$-\frac{1}{2}a_4' + \frac{b_4'}{4b_4}$ each	$\frac{1}{2}H$ each
total	$\frac{3}{2}a_4' - \frac{3}{2}a_4' + \frac{3}{4}\frac{b_4'}{b_4} = \frac{3}{4}\frac{b_4'}{b_4}$	$6\cdot\frac{1}{2}H = 3H$

$$\sum_\mu \gamma^\mu\Omega_\mu = 3H\,\gamma^{(x0)} + \frac{3}{4}\,\frac{b_4'}{b_4}\,\gamma^{(x4)}.$$

In words. Along the time direction the inflating 3-space and the deflating extra times push with equal and opposite strength $\pm\frac{3}{2}a_4'$, and these contributions cancel exactly, for every function $a_4(x_4)$. A changing b_4 stretches the three extra times and leaves the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$. Along the hidden direction all six warped directions push the same way, and their contributions add. For a constant b_4, in particular on the backgrounds $b_4 = 1$ of this book, the result is the constant matrix $3H\gamma^{(x0)}$: it contains neither a_4 nor x_4 nor x_0.

Reading off the coefficients with traces. Notebook 06a finds α_μ and β_μ with traces (the **trace** of a square matrix is the sum of its diagonal entries). For two different gammas $\mathrm{tr}(\gamma^a\gamma^b) = 0$, while $\mathrm{tr}(\gamma^{(x4)}\gamma^{(x4)}) = \mathrm{tr}(-1) = -16$ and $\mathrm{tr}(\gamma^{(x0)}\gamma^{(x0)}) = +16$ (Chapter 4). So for $M = \alpha\gamma^{(x4)} + \beta\gamma^{(x0)}$:

$$\mathrm{tr}(M\gamma^{(x4)}) = \alpha(-16) + \beta\cdot 0, \qquad \mathrm{tr}(M\gamma^{(x0)}) = \alpha\cdot 0 + \beta\cdot 16,$$

hence $\alpha = -\mathrm{tr}(M\gamma^{(x4)})/16$ and $\beta = \mathrm{tr}(M\gamma^{(x0)})/16$. The notebook then checks that $M - \alpha\gamma^{(x4)} - \beta\gamma^{(x0)}$ is the zero matrix, so that nothing else is hidden in M.

6.9 Why a_4 drops out and b_4 does not: the divergence form

The cancellation of Section 6.8 is not an accident. Two facts explain it without computing Ω_μ at all.

Fact 1: for each μ separately, $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu = 0$ (no sum). In the diagonal vielbein Ω_μ contains only generators $S^{(\mu)b}$ with $b \neq \mu$ (Section 6.6), and γ^μ is a multiple of $\gamma^{(\mu)}$. For one such generator:

$$\gamma^{(\mu)}\,\tfrac{1}{2}\gamma^{(\mu)}\gamma^{(b)} = \tfrac{1}{2}\eta_{\mu\mu}\gamma^{(b)}, \qquad \tfrac{1}{2}\gamma^{(\mu)}\gamma^{(b)}\,\gamma^{(\mu)} = -\tfrac{1}{2}\gamma^{(\mu)}\gamma^{(\mu)}\gamma^{(b)} = -\tfrac{1}{2}\eta_{\mu\mu}\gamma^{(b)}$$

(the Clifford relation; in the second product the two different gammas $\gamma^{(b)}$ and $\gamma^{(\mu)}$ are exchanged at the cost of a sign). The two products are opposite, so they anticommute, and so do the combinations.

The divergence form. Take the covariant constancy $D_\mu\gamma^\nu = 0$ of Section 6.7, put $\nu = \mu$ and sum over μ:

$$\sum_\mu \partial_\mu \gamma^\mu + \sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda}\gamma^\lambda + \sum_\mu \left(\Omega_\mu \gamma^\mu - \gamma^\mu \Omega_\mu\right) = 0.$$

The contracted Christoffel symbol of a diagonal metric is $\sum_\mu \Gamma^\mu{}_{\mu\lambda} = \sum_\mu \partial_\lambda \ln f_\mu = \partial_\lambda \ln\left(\prod_\mu f_\mu\right) = \partial_\lambda \ln\sqrt{|g|}$ (cases (a) and (b) of Section 6.3; the logarithm of a product is the sum of the logarithms; Section 6.2). So the first two sums are

$$\sum_\lambda \Big(\partial_\lambda \gamma^\lambda + \frac{\partial_\lambda \sqrt{|g|}}{\sqrt{|g|}}\gamma^\lambda\Big) = \frac{1}{\sqrt{|g|}} \sum_\lambda \partial_\lambda(\sqrt{|g|}\,\gamma^\lambda)$$

(the product rule read backwards). By Fact 1, $\Omega_\mu \gamma^\mu = -\gamma^\mu \Omega_\mu$, so the third sum is $-2\sum_\mu \gamma^\mu \Omega_\mu$. Solving for the contraction:

$$\sum_\mu \gamma^\mu \Omega_\mu = \frac{1}{2\sqrt{|g|}} \sum_\mu \partial_\mu(\sqrt{|g|}\,\gamma^\mu).$$

The right side is built from the volume factor and the vielbein alone.

Fact 2: the product structure. For the diagonal vielbein $\sqrt{|g|}\,\gamma^\mu = \left(\prod_c f_c\right)\gamma^{(\mu)}/f_\mu = \left(\prod_{c\neq\mu} f_c\right)\gamma^{(\mu)}$ (no sum over μ). The term ∂_μ of this product can be nonzero only if the product depends on its own coordinate x_μ, that is only for $\mu = x0$ or $\mu = x4$. For the hidden direction:

$$\prod_{c\neq x0} f_c = e^{3a_4} s^3 \cdot 1 \cdot e^{-3a_4} b_4^{3/2} s^3 = b_4^{3/2} s^6 = b_4^{3/2} \sin z,$$

$$\frac{1}{2b_4^{3/2}\cos z}\,\partial_0\big(b_4^{3/2}\sin z\big)\,\gamma^{(x0)} = \frac{6H\cos z}{2\cos z}\gamma^{(x0)} = 3H\,\gamma^{(x0)}$$

(the chain rule with $dz/dx_0 = 6H$; b_4 does not depend on x_0; then cancel $b_4^{3/2}\cos z$). For the time:

$$\prod_{c\neq x4} f_c = \cot z \cdot e^{3a_4} s^3 \cdot e^{-3a_4} b_4^{3/2} s^3 = b_4^{3/2} \sin z \cot z = b_4^{3/2} \cos z,$$

$$\frac{1}{2b_4^{3/2}\cos z}\,\partial_4\big(b_4^{3/2}\cos z\big)\,\gamma^{(x4)} = \frac{\frac{3}{2}b_4^{1/2}b_4'}{2b_4^{3/2}}\gamma^{(x4)} = \frac{3}{4}\,\frac{b_4'}{b_4}\,\gamma^{(x4)}$$

(Section 6.2; the factors $e^{\pm 3a_4}$ cancel, so a_4 is gone; the power rule gives $\partial_4 b_4^{3/2} = \frac{3}{2}b_4^{1/2}b_4'$). **The time direction contributes only through** b_4, and nothing when b_4 is constant. This is the deeper reason for the cancellation of the a_4' terms in Section 6.8: the 7-volume of a slice does not change with the inflation of 3-space and the deflation of the extra times, only with b_4. So the divergence form gives $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ again, by a second and much shorter route. Notebook 06a checks Fact 1 for every μ, the divergence form and the eight products (In [18]), and once more with a calculator's method, a central difference (In [19]).

6.10 The Dirac operator written out, non-triviality and the negative control

The Dirac operator. Combine $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ with the contraction:

$$\sum_\mu \gamma^\mu D_\mu \Psi = \sum_a \frac{1}{f_a}\gamma^{(a)}\partial_a \Psi + 3H\gamma^{(x0)}\Psi + \frac{3}{4}\,\frac{b_4'}{b_4}\,\gamma^{(x4)}\Psi,$$

that is, with the factors written out,

$$\begin{aligned}&\tan z\,\gamma^{(x0)}\partial_0\Psi + e^{-a_4}s^{-1}\big(\gamma^{(x1)}\partial_1 + \gamma^{(x2)}\partial_2 + \gamma^{(x3)}\partial_3\big)\Psi + \gamma^{(x4)}\partial_4\Psi \\ &\quad + e^{a_4}b_4^{-1/2}s^{-1}\big(\gamma^{(x5)}\partial_5 + \gamma^{(x6)}\partial_6 + \gamma^{(x7)}\partial_7\big)\Psi + 3H\gamma^{(x0)}\Psi + \frac{3}{4}\,\frac{b_4'}{b_4}\,\gamma^{(x4)}\Psi.\end{aligned}$$

This is the left side of the field equation of both fields; the right side is $(m + U'(S))\Psi$ with $S = \bar\Psi\Psi$ (Chapter 7). The Revision records write out all sixteen component equations (formula `field_equation_components`, with b_4 and at $b_4 = 1$), and Notebook 06a compares each of them with its own computation (In [20]). **Where the deflation enters.** It does not enter $\gamma^\mu\Omega_\mu$, but it enters every derivative term through the factors $1/f_a$: as 3-space inflates the 3-space derivatives are weighted less and less (e^{-a_4}/s), and as the extra times deflate the extra-time derivatives are weighted more and more ($e^{a_4}b_4^{-1/2}/s$). Figure 06a.9 draws these factors.

The block form. In the chiral split $\Psi = (\psi_-, \psi_+)$ (components 1 to 8 and 9 to 16, Chapter 5) every gamma of the author has zero blocks on the diagonal, $\gamma^{(xa)} = \begin{pmatrix} 0 & \bar\tau_a \\ \tau_a & 0 \end{pmatrix}$, and $\gamma^{(x0)}$ has the 8×8 identity in both off-diagonal blocks. So $3H\gamma^{(x0)}$ maps the first eight components onto the

last eight and back with the factor $3H$, which is why its picture (figure 06a.7) shows the value 3 on two diagonal lines. Record: formula `field_equation_blocks`; `wolfram-field-theory.json`, check `block_form`.

Non-triviality. Write $M = 3H\gamma^{(x0)} + c\,\gamma^{(x4)}$ with $c = \frac{3}{4}b_4'/b_4$ for the term of the field equation. Line by line,

$$MM = 9H^2\gamma^{(x0)}\gamma^{(x0)} + 3Hc\big(\gamma^{(x0)}\gamma^{(x4)} + \gamma^{(x4)}\gamma^{(x0)}\big) + c^2\gamma^{(x4)}\gamma^{(x4)} = \big(9H^2 - c^2\big)\,1$$

(multiply out; $(\gamma^{(x0)})^2 = \eta_{00}1 = 1$, $(\gamma^{(x4)})^2 = \eta_{44}1 = -1$, and the middle bracket is the anticommutator of two different gammas, which is 0). When $9H^2 - c^2 \neq 0$, $M\Psi = 0$ gives $\Psi = MM\Psi/(9H^2 - c^2) = 0$ (multiply from the left by M and divide by the number). So **the term vanishes only for $\Psi = 0$, except at times where** $|b_4'/b_4| = 4H$ ($c = \pm 3H$). For a constant b_4, in particular on the backgrounds $b_4 = 1$, $M = 3H\gamma^{(x0)}$ and the exception never occurs: for every $H > 0$ and every field that is not identically zero, the term is present (PROVED; at $b_4 = 1$ `wolfram-field-theory.json`, checks `nontriviality_1_dirac16complex` and `nontriviality_2_dirac16complex00`, for the two fields). Where $|b_4'/b_4| = 4H$, $M = 3H(\gamma^{(x0)} \pm \gamma^{(x4)})$ is not zero but squares to zero, and its rank is 8: there it sends an 8-dimensional set of nonzero fields to zero (`python-field-theory-b4.json`, check `gravity_term_square_b4`; Notebook 06a, In [20], computes the rank exactly). Section 6.29 states precisely how far these statements reach.

The negative control: extra times that INFLATE. Is the cancellation of the a_4' terms caused by the deflation, or is it an accident of the algebra? Take $b_4 = 1$, so that only the deflation is changed, and change the metric so that the extra times inflate like 3-space: $g_{tt} = -e^{+2a_4}\sin^{1/3} z$, factors $f_t = e^{+a_4}s$. Repeat Section 6.6: now $\partial_4 f_t = +a_4' f_t$, so

$$\omega_{x_t\,x_t\,x4} = (-1)\frac{a_4' f_t}{1} = -a_4' f_t, \qquad \omega_{x_t\,x4\,x_t} = +a_4' f_t, \qquad \omega_{x_t\,x_t\,x0} = -H f_t$$

(the formula $\omega_{\mu\,\mu b} = \eta_{\mu\mu}\partial_b f_\mu / f_b$; the antisymmetry; $\partial_0 f_t$ is unchanged), and $\Omega_{x_t} = f_t(a_4' S^{x4\,x_t} - HS^{x_t\,x0})$. Repeat Section 6.8:

$$\gamma^{x5}\Omega_{x5} = \tfrac{1}{2}a_4'\,\gamma^{(x5)}\gamma^{(x4)}\gamma^{(x5)} - \tfrac{1}{2}H\,\gamma^{(x5)}\gamma^{(x5)}\gamma^{(x0)} = \tfrac{1}{2}a_4'\,\gamma^{(x4)} + \tfrac{1}{2}H\,\gamma^{(x0)}$$

(the same two products as before). Now all six warped directions contribute $+\frac{1}{2}a_4'$ along the time, and

$$\sum_\mu \gamma^\mu\Omega_\mu\Big|_{\text{control}} = 3a_4'\,\gamma^{(x4)} + 3H\,\gamma^{(x0)}.$$

The divergence form of Section 6.9 agrees. With inflating extra times the volume factor is $\sqrt{|g|} = \cot z \cdot e^{3a_4}s^3 \cdot 1 \cdot e^{3a_4}s^3 = e^{6a_4}\cos z$, which now changes with time, and

$$\frac{1}{2\sqrt{|g|}}\,\partial_4\Big(\prod_{c\neq x4} f_c\Big) = \frac{\partial_4(e^{6a_4}\cos z)}{2e^{6a_4}\cos z} = \frac{6a_4' e^{6a_4}\cos z}{2e^{6a_4}\cos z} = 3a_4'$$

(the product without $x4$ is the whole volume factor because $f_4 = 1$; the chain rule gives $\partial_4 e^{6a_4} = 6a_4' e^{6a_4}$; then cancel). **The cancellation of the a_4' terms in the author's metric is caused by the deflation.** The hidden term $3H\gamma^{(x0)}$ is the same in both cases: it comes from $x0$, not from the time dependence. PROVED; lead report, check `negative_control_inflating_extra_times`; Notebook 06a, In [22], and figure 10.

6.11 Example: Notebook 06a

Notebook 06a puts Sections 6.2 to 6.10 to work with exact algebra. It reads the author's eight gammas from the record `Revision/algebra/gammas.json`, checks the Clifford relations, and defines four general functions (Christoffel symbols, canonical spin connection, spinor connection, curved gammas) that work in any number of dimensions. It first applies them to the polar plane of Section 6.5 and draws the turning frame and the half-angle spinor rotation. Then it builds the author's metric with arbitrary functions $a_4(x_4)$ and $b_4(x_4)$ and computes, exactly: the vielbein, the volume factor, the 25 Christoffel symbols, the 12 components of the spin connection, the 512 equations of the vielbein postulate, Ω_μ, the covariant constancy of the gammas, the eight terms $\gamma^\mu\Omega_\mu$ and their sum $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$, the divergence form, the Dirac operator for sixteen arbitrary component functions, the square of the term, and the negative control. It compares every result that the Revision records also contain with the records (with b_4, and at $b_4 = 1$), draws ten figures, needs no Rust, runs in about a minute and ends with the line ALL 36 CHECKS PASSED (notebook 06a).

6.12 How to run Notebook 06a

Step 1. What this notebook does and what it needs.

Notebook 06a (Vielbein, spin connection and the term gamma^mu Omega_mu of the field equation) is the file `Revision/textbook/notebooks/06a_spin_connection.ipynb` of the repository Dirac_claude. Starting from the author's metric with the functions a4(x4) and b4(x4) and the author's real 16 x 16 gamma matrices, it computes exactly, with sympy, the diagonal vielbein, the Christoffel symbols, the canonical spin connection, the spinor connection Omega_mu, the covariant derivative of a spinor and the term gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4) of the field equation; it shows that the a4' terms of the three inflating and the three deflating directions cancel while a b4' term remains (zero for constant b4, as on the backgrounds b4 = 1), checks the results against the Revision records, repeats the computation for a negative control with inflating extra times, works a two-dimensional warm-up (the polar plane), and draws ten teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
```

```
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 06a_spin_connection.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows

a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06a_spin_connection.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 06a_spin_connection.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/06a.captions.json`
- `Revision/textbook/figures/06a_1_polar_frame_and_spin_rotation.png`
- `Revision/textbook/figures/06a_2_vielbein_factors.png`
- `Revision/textbook/figures/06a_3_christoffel_pattern.png`
- `Revision/textbook/figures/06a_4_omega_heat_maps.png`
- `Revision/textbook/figures/06a_5_spinor_connection_heat_maps.png`
- `Revision/textbook/figures/06a_6_gamma_omega_per_direction.png`
- `Revision/textbook/figures/06a_7_gamma_omega_cancellation.png`
- `Revision/textbook/figures/06a_8_divergence_form.png`
- `Revision/textbook/figures/06a_9_derivative_coefficients.png`
- `Revision/textbook/figures/06a_10_negative_control.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all ten figure files exist
ALL 36 CHECKS PASSED (notebook 06a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/06a_spin_connection.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 06a_spin_connection.ipynb
python -m nbconvert --execute --inplace 06a_spin_connection.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook reads Revision records from the repository; open it inside the folder Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single downloaded notebook file is not enough).
- a cell runs for many minutes: the exact algebra of sympy is slow on old computers; the whole notebook needs about a minute on a 2024 laptop, and up to about two minutes while other programs use the processor. Wait, or close the other programs.

6.13 Notebook 06a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/06a_spin_connection.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A spinor field (a column of 16 numbers at every point, such as the author's fields
dirac16complex and dirac16complex00) does not see the metric directly. It sees it
through a **vielbein** (a set of eight perpendicular unit directions at every point)
and through the **spin connection** (the rate at which these directions turn from
point to point). This notebook computes both, exactly, for the author's primordial
metric with its two functions $a_4(x_4)$ and $b_4(x_4)$, and the one combination
that enters the field equation,

$$\gamma^\mu \Omega_\mu = 3 H \gamma^{(x0)} + \tfrac34\,\frac{b_4'}{b_4}\,
\gamma^{(x4)} ,$$

which is $3H\gamma^{(x0)}$ when $b_4$ is constant, as on the backgrounds of this
book ($b_4 = 1$). It

- starts with a warm-up in two dimensions (the flat plane in polar coordinates),
  where every step can be followed by hand;
- builds the diagonal vielbein of the author's metric and checks that it gives the
  metric back;
- computes the 25 independent nonzero Christoffel symbols, the canonical spin
  connection $\omega_{\mu ab}$ (12 independent nonzero components) and the spinor
  connection $\Omega_\mu$ (16 x 16 matrices built from the author's gammas);
- checks the vielbein postulate (512 equations), the antisymmetry of $\omega$ and
  the covariant constancy of the gammas (64 matrix equations);
- computes $\gamma^\mu\Omega_\mu$ direction by direction and shows that the
  $a_4'$ terms along the time $x4$ cancel between the three inflating directions
```

```
  $x1, x2, x3$ and the three deflating extra times $x5, x6, x7$, that the extra
  times leave the term $\frac34(b_4'/b_4)\gamma^{(x4)}$, and that the six terms
  along the hidden direction $x0$ add up to $3H\gamma^{(x0)}$;
- explains why the function $a_4(x_4)$ drops out and $b_4(x_4)$ does not (the
  divergence form);
- writes the covariant derivative and the Dirac operator out in full and compares
  all 16 component equations with the Revision records (with $b_4$, and at
  $b_4 = 1$);
- shows when the term vanishes for a nonzero field: never when $b_4$ is
  constant, and only where $|b_4'/b_4| = 4H$ otherwise;
- repeats the computation for a NEGATIVE CONTROL, a metric whose extra times
  inflate instead of deflating (at $b_4 = 1$): there a term
  $3 a_4' \gamma^{(x4)}$ survives;
- draws ten teaching plots.

Every result that the Revision record also contains is compared with the record,
and the check prints the record file and the name of its check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 06a (Vielbein, spin connection and the term gamma^mu Omega_mu of the field
equation) is the file ‘Revision/textbook/notebooks/06a_spin_connection.ipynb‘ of the
repository Dirac_claude. Starting from the author’s metric with the functions a4(x4) and
b4(x4) and the author’s real 16 x 16 gamma matrices, it computes exactly, with sympy, the
diagonal vielbein, the Christoffel symbols, the canonical spin connection, the spinor
connection Omega_mu, the covariant derivative of a spinor and the term gamma^mu Omega_mu
= 3 H gamma^(x0) + (3/4)(b4’/b4) gamma^(x4) of the field equation; it shows that the a4’
terms of the three inflating and the three deflating directions cancel while a b4’ term
remains (zero for constant b4, as on the backgrounds b4 = 1), checks the results against
the Revision records, repeats the computation for a negative control with inflating extra
times, works a two-dimensional warm-up (the polar plane), and draws ten teaching plots.
It needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
```

"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in
this one window only; it changes nothing permanently.

macOS (zsh):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 06a_spin_connection.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06a_spin_connection.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 06a_spin_connection.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/06a.captions.json‘
- ‘Revision/textbook/figures/06a_1_polar_frame_and_spin_rotation.png‘
- ‘Revision/textbook/figures/06a_2_vielbein_factors.png‘
- ‘Revision/textbook/figures/06a_3_christoffel_pattern.png‘
- ‘Revision/textbook/figures/06a_4_omega_heat_maps.png‘
- ‘Revision/textbook/figures/06a_5_spinor_connection_heat_maps.png‘
- ‘Revision/textbook/figures/06a_6_gamma_omega_per_direction.png‘
- ‘Revision/textbook/figures/06a_7_gamma_omega_cancellation.png‘
- ‘Revision/textbook/figures/06a_8_divergence_form.png‘
- ‘Revision/textbook/figures/06a_9_derivative_coefficients.png‘
- ‘Revision/textbook/figures/06a_10_negative_control.png‘

It changes no other file of the repository; running it headless or saving it in

JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all ten figure files exist
ALL 36 CHECKS PASSED (notebook 06a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/06a_spin_connection.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 06a_spin_connection.ipynb
  python -m nbconvert --execute --inplace 06a_spin_connection.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues

and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook reads Revision records from the repository; open it inside the folder Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single downloaded notebook file is not enough).
- a cell runs for many minutes: the exact algebra of sympy is slow on old computers; the whole notebook needs about a minute on a 2024 laptop, and up to about two minutes while other programs use the processor. Wait, or close the other programs.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 06a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 06a (Vielbein, spin connection and the term gamma^mu Omega_mu of the field
# equation) is the file Revision/textbook/notebooks/06a_spin_connection.ipynb of the
# repository Dirac_claude. Starting from the author's metric with the functions a4(x4)
# and b4(x4) and the author's real 16 x 16 gamma matrices, it computes exactly, with
# sympy, the diagonal vielbein, the Christoffel symbols, the canonical spin connection,
# the spinor connection Omega_mu, the covariant derivative of a spinor and the term
# gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4) of the field equation; it
# shows that the a4' terms of the three inflating and the three deflating directions
# cancel while a b4' term remains (zero for constant b4, as on the backgrounds b4 = 1),
# checks the results against the Revision records, repeats the computation for a negative
# control with inflating extra times, works a two-dimensional warm-up (the polar plane),
# and draws ten teaching plots. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
```

```
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 06a_spin_connection.ipynb
#
```

```
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 1 minute
# on a typical laptop. Scroll to the end and compare the last printed lines with the
# lines in the step "What the notebook writes and what you must see" below. To keep the
# results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the
# menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 06a_spin_connection.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 06a_spin_connection.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/06a.captions.json
# - Revision/textbook/figures/06a_1_polar_frame_and_spin_rotation.png
# - Revision/textbook/figures/06a_2_vielbein_factors.png
# - Revision/textbook/figures/06a_3_christoffel_pattern.png
# - Revision/textbook/figures/06a_4_omega_heat_maps.png
# - Revision/textbook/figures/06a_5_spinor_connection_heat_maps.png
# - Revision/textbook/figures/06a_6_gamma_omega_per_direction.png
# - Revision/textbook/figures/06a_7_gamma_omega_cancellation.png
# - Revision/textbook/figures/06a_8_divergence_form.png
# - Revision/textbook/figures/06a_9_derivative_coefficients.png
# - Revision/textbook/figures/06a_10_negative_control.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
```

```
#
#     PASS all ten figure files exist
#     ALL 36 CHECKS PASSED (notebook 06a)
#
# and the notebook must show 10 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/06a_spin_connection.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 06a_spin_connection.ipynb
#     python -m nbconvert --execute --inplace 06a_spin_connection.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook
#   reads Revision records from the repository; open it inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a
#   single downloaded notebook file is not enough).
# - a cell runs for many minutes: the exact algebra of sympy is slow on old computers;
#   the whole notebook needs about a minute on a 2024 laptop, and up to about two minutes
#   while other programs use the processor. Wait, or close the other programs.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Coordinates** $x0, \dots, x7$: the eight numbers that name a point, with the
  author's names: $x0$ the **hidden direction**; $x1, x2, x3$ ordinary 3-space;
  $x4$ the time; $x5, x6, x7$ the three **extra times**. In Python lists they
  have the positions 0 to 7 (Python counts from 0) in the same order, so `x[0]`
  is $x0$ and `x[4]` is $x4$.
- **Metric** $g_{\mu\nu}$: the rule that turns small coordinate steps into squared
  lengths, $ds^2 = \sum_\mu g_{\mu\mu} (dx^\mu)^2$ for the author's (diagonal)
  metric. A positive $g_{\mu\mu}$ makes direction $\mu$ **space-like**, a negative
  one **time-like**.
- **Signature (4,4)**: four space-like directions ($x0, x1, x2, x3$) and four
  time-like ones ($x4, x5, x6, x7$).
- **Frame metric** $\eta_{ab}$: the constant diagonal matrix
  $\mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order $x0, \dots, x7$.
- **Vielbein** $e^a{}_\mu$ (German "many legs"): at every point eight directions
  that are perpendicular and of unit length, so that
  $g_{\mu\nu} = \sum_{a} \eta_{aa} e^a{}_\mu e^a{}_\nu$. The index $a$ (a
  **frame index**) numbers the eight directions; $\mu$ (a **coordinate index**)
  numbers the coordinates. Its **inverse** $e_a{}^\mu$ satisfies
  $\sum_\mu e^a{}_\mu e_b{}^\mu = \delta^a_b$ (1 if $a = b$, else 0).
- **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$: the numbers that say how the
  coordinate directions change from point to point; computed from the first
  derivatives of the metric.
- **Spin connection** $\omega_\mu{}^a{}_b$: the numbers that say how the vielbein
  turns when one moves along $x^\mu$. The **canonical** one is fixed by the
  **vielbein postulate** (below). Lowering the first frame index with $\eta$ gives
  $\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b$, which is **antisymmetric**:
  $\omega_{\mu ab} = -\omega_{\mu ba}$.
- **Gamma matrices** $\gamma^a$: the author's eight real 16 x 16 matrices with
  $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\,1$ (the **Clifford
  relation**; $1$ is the 16 x 16 identity matrix). **Curved gammas**:
  $\gamma^\mu = \sum_a e_a{}^\mu \gamma^a$.
- **Commutator** $[A, B] = AB - BA$; **anticommutator** $\{A, B\} = AB + BA$.
- $S^{ab} = \frac14[\gamma^a, \gamma^b]$: the 28 matrices (one for each pair
  $a < b$) that turn spinors when the frame is turned.
```

```
- **Spinor connection** $\Omega_\mu = \frac12 \sum_{a,b}\omega_{\mu ab} S^{ab}$: a
  16 x 16 matrix for every $\mu$.
- **Covariant derivative** of a spinor: $D_\mu \Psi = \partial_\mu \Psi +
  \Omega_\mu \Psi$ ($\partial_\mu$ is the partial derivative with respect to
  $x^\mu$). **Dirac operator**: $\gamma^\mu D_\mu = \sum_\mu \gamma^\mu D_\mu$.
- **Trace** $\mathrm{tr}\,M$: the sum of the diagonal entries of a square matrix.
- **Exact** computation: with symbols and fractions (sympy), not with rounded
  decimal numbers; an exact check that an expression is zero proves it for ALL
  values of the symbols.
- **Negative control**: a deliberately changed case in which the effect must NOT
  occur (or must occur differently); it shows that a check can fail and that the
  result depends on the feature that was changed.
- **Heat map**: a picture of a matrix in which every entry is a small coloured
  square; here red is positive, blue is negative and white is zero.
```

Text cell:

```
## 4. The physical and mathematical situation

**The author's metric.** With $z = 6 H x_0$ in the interval $(0, \pi/2)$, a positive
constant $H$ and two functions of the time, $a_4(x_4)$ and $b_4(x_4) > 0$,

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}\sin^{1/3}z,\ e^{2a_4}\sin^{1/3}z,\
e^{2a_4}\sin^{1/3}z,\ -1,\ -e^{-2a_4}b_4\sin^{1/3}z,\ -e^{-2a_4}b_4\sin^{1/3}z,\
-e^{-2a_4}b_4\sin^{1/3}z\big)$$

in the order $x0, \dots, x7$. When $a_4$ grows, lengths along $x1, x2, x3$ grow
like $e^{a_4}$ (3-space **inflates**) and lengths along the extra times
$x5, x6, x7$ shrink like $e^{-a_4}$ (the extra times **deflate exponentially**);
$b_4$ multiplies the squared lengths of the extra times. On the backgrounds of this
book $b_4 = 1$ (Chapter 3: an empty spacetime has a constant $b_4$, and a constant
$b_4$ only rescales $x5, x6, x7$); every result below holds for every $b_4$.

**The diagonal vielbein.** Because $g$ is diagonal, the vielbein can be chosen
diagonal: $e^a{}_\mu = f_a\,\delta^a_\mu$ with $f_a = \sqrt{|g_{aa}|}$:

$$f = \big(\cot z,\ e^{a_4}s,\ e^{a_4}s,\ e^{a_4}s,\ 1,\ e^{-a_4}b_4^{1/2}s,\
e^{-a_4}b_4^{1/2}s,\ e^{-a_4}b_4^{1/2}s\big), \qquad s = \sin^{1/6} z \,.$$

**The formulas used** (the standard ones of general relativity with spinors):

$$\Gamma^\lambda{}_{\mu\nu} = \tfrac12 \sum_\rho g^{\lambda\rho}\big(\partial_\mu
g_{\rho\nu} + \partial_\nu g_{\rho\mu} - \partial_\rho g_{\mu\nu}\big),$$

$$\omega_\mu{}^a{}_b = \sum_\nu e^a{}_\nu \Big(\partial_\mu e_b{}^\nu +
\sum_\lambda \Gamma^\nu{}_{\mu\lambda} e_b{}^\lambda\Big), \qquad
\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b \,,$$

$$\Omega_\mu = \tfrac12 \sum_{a,b} \omega_{\mu ab} S^{ab}, \qquad D_\mu\Psi =
\partial_\mu\Psi + \Omega_\mu\Psi, \qquad \gamma^\mu = \sum_a e_a{}^\mu\gamma^a \,.$$

The formula for $\omega$ is the unique solution of the **vielbein postulate**
$\partial_\mu e^a{}_\nu - \sum_\lambda \Gamma^\lambda{}_{\mu\nu} e^a{}_\lambda +
```

```
\sum_b \omega_\mu{}^a{}_b e^b{}_\nu = 0$: the vielbein is constant for the full
covariant derivative. The notebook checks this equation in all 512 components.

**What is PROVED here (exact, sympy) and what it means.** In the diagonal vielbein,
$\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \frac34(b_4'/b_4)\gamma^{(x4)}$ for every
$H > 0$ and all functions $a_4(x_4)$ and $b_4(x_4) > 0$; for a constant $b_4$ it is
$3H\gamma^{(x0)}$. This term appears in the field equation $\gamma^\mu D_\mu\Psi =
(m + U'(S))\Psi$ of both fields. Its value belongs to the diagonal vielbein: the
next notebook of this chapter (06b) shows that in another vielbein of the same
metric the contraction changes, and even vanishes, and that a rescaling of the
field removes it. What no choice can remove is the curvature of the metric.
```

```
## 5. The tools: sympy and the author's gamma matrices

The next cell imports numpy (numbers for the plots) and sympy (exact algebra),
reads the author's eight gamma matrices from the Revision record
`Revision/algebra/gammas.json`, and checks two of their properties: the 64
Clifford relations, and that there are eight of them, each a 16 x 16 matrix whose
entries are all real numbers. It then builds the 28 matrices $S^{ab} =
\frac14[\gamma^a, \gamma^b]$.

The first lines of the next cell change one setting of Jupyter: printed text is
sent to the screen when a cell has finished (or just before a figure is shown),
not every 0.2 seconds. This changes no result; it makes the printed text arrive in
the same pieces in every run, which the book's checking tool needs.
```

In [2]:

```
import sys  # the Python system module (here: the stream of printed text)

# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
import numpy as np  # arrays of decimal numbers (only for the plots)
import sympy as sp  # exact algebra and calculus with symbols

```

Text cell:

```
The next cell defines four small helpers that the rest of the notebook uses.

- `is_zero(expr)` decides EXACTLY whether a sympy expression is zero for all values
  of its symbols. It first tries a fast route (write every sine and cosine through
  exponential functions, multiply out, cancel common factors) and then sympy's
  general `simplify`. It never says "zero" for an expression that is not zero; at
  worst it fails to recognise a zero, and then a check fails visibly.
- `matrix_is_zero(M)` applies `is_zero` to every entry of a matrix.
- `record_passed(path, name)` opens a Revision report (a JSON file) and returns
  True when the report records the check `name` as passed.
- `record_formula(key, names, formulas)` reads a formula of a record, written in
  the notation of the Wolfram Language, and turns it into a sympy expression with
  sympy's reader `parse_mathematica`. Two records are read:
  `Revision/theory/field-theory.json` (the metric at $b_4 = 1$) and
  `Revision/theory/field-theory-b4.json` (the metric with $b_4(x_4)$).
```

## 6. Four general formulas as Python functions

The next cell turns the formulas of Section 4 into four Python functions. They work
in ANY number of dimensions and for ANY vielbein, so the same functions serve the
two-dimensional warm-up and the author's eight-dimensional metric.

- `christoffel(g, coords)`: the Christoffel symbols of the metric matrix `g`;
  `Gam[l][m][n]` is $\Gamma^l{}_{mn}$. Because $\Gamma^l{}_{mn} = \Gamma^l{}_{nm}$,
  each pair $(m, n)$ is computed once.
- `spin_connection(e, Gam, coords, eta)`: the canonical spin connection with the
  first frame index lowered, `omega[mu][a][b]` $= \omega_{\mu ab}$. The vielbein is
  the matrix `e` with `e[a, mu]` $= e^a{}_\mu$ (row = frame index, column =
  coordinate index); its inverse matrix `E = e.inv()` has `E[mu, a]` $=
  e_a{}^\mu$, because $\sum_\mu e^a{}_\mu e_b{}^\mu = \delta^a_b$ says exactly
  `e * E = 1`.
- `spinor_connection(omega, S)`: $\Omega_\mu = \frac12\sum_{a,b}\omega_{\mu ab}
  S^{ab}$. Since both $\omega_{\mu ab}$ and $S^{ab}$ change sign when $a$ and $b$
  are exchanged, the terms $(a, b)$ and $(b, a)$ are equal, and the factor
  $\frac12$ is used up by summing over $a < b$ only.
- `curved_gammas(e, gammas)`: $\gamma^\mu = \sum_a e_a{}^\mu \gamma^a$.

Every nonzero result is simplified with sympy's `simplify`, so that it prints in a
short form.
```

In [4]:

```

## 7. A warm-up in two dimensions: the flat plane in polar coordinates

Before eight dimensions, two. A point of the flat plane has the polar coordinates
$r$ (distance from the centre) and $\varphi$ (angle). The metric is
$ds^2 = dr^2 + r^2 d\varphi^2$, so $g = \mathrm{diag}(1, r^2)$ and $\eta =
\mathrm{diag}(1, 1)$. The unit directions are the radial direction (frame index 0)
and the angular direction (frame index 1); a step $d\varphi$ has the length
$r\,d\varphi$, so the vielbein is $e = \mathrm{diag}(1, r)$. Two 2 x 2 matrices with
the Clifford relation of the plane are the Pauli matrices $\sigma_1$ and
$\sigma_2$, so $\gamma^0 = \sigma_1$ and $\gamma^1 = \sigma_2$.

The next cell computes everything with the general functions and checks the
results that can be worked by hand:
$\Gamma^r{}_{\varphi\varphi} = -r$, $\Gamma^\varphi{}_{r\varphi} = 1/r$;
$\omega_{\varphi 01} = -1$ (the frame turns by one radian per radian of
$\varphi$); $\Omega_\varphi = -\frac{i}{2}\sigma_3$; and
$\gamma^\mu\Omega_\mu = \sigma_1/(2r)$, so that the Dirac operator of the plane in
polar coordinates is $\sigma_1(\partial_r + \frac{1}{2r}) + \frac{\sigma_2}{r}
\partial_\varphi$. The plane is flat, so the curvature of the spinor connection,
$F_{r\varphi} = \partial_r\Omega_\varphi - \partial_\varphi\Omega_r +
[\Omega_r, \Omega_\varphi]$, must vanish; the cell checks that too. A change of
frame by a spin transformation $R(\varphi)$ changes the spinor connection into
$R\,\Omega_\varphi R^{-1} - (\partial_\varphi R)R^{-1}$. The Cartesian frame has
no connection, and the cell checks that $\Omega_\varphi = -(\partial_\varphi
U)U^{-1}$ for the spinor rotation $U(\varphi) = \cos\frac{\varphi}{2} +
i\sin\frac{\varphi}{2}\,\sigma_3$: this is the rule with $R = U$ applied to the
connection 0 of the Cartesian frame, so $U$ carries the Cartesian frame into the
polar frame. Finally it checks that the inverse rotation $U^{-1}$ removes the
connection: the rule with $R = U^{-1}$ gives $U^{-1}\Omega_\varphi U -
(\partial_\varphi U^{-1})U = 0$. In a flat space the spin connection is only the
turning of the chosen frame.
```

Text cell:

```
The next cell draws two pictures of the warm-up. On the left, the unit radial
direction (black arrows) and the unit angular direction (orange arrows) at twelve
angles on two circles: the frame turns as one goes around, by exactly the angle
$\varphi$, which is why $\omega_{\varphi 01} = -1$ (one radian of frame rotation per
radian of $\varphi$; the sign records the sense of rotation). On the right, the
real part and the imaginary part of the entry $U_{11} = \cos\frac\varphi2 +
i\sin\frac\varphi2$ of the spinor rotation $U(\varphi)$ that carries the Cartesian
frame into the polar frame (its inverse $U^{-1}$ removes the connection), for
$\varphi$ from $0$ to $4\pi$: after one full turn ($\varphi = 2\pi$) $U = -1$, and
```

```
only after two full turns is $U = +1$ again. A spinor turns by half the angle of the
frame; this is the "double cover" of rotations by spinor transformations.
```

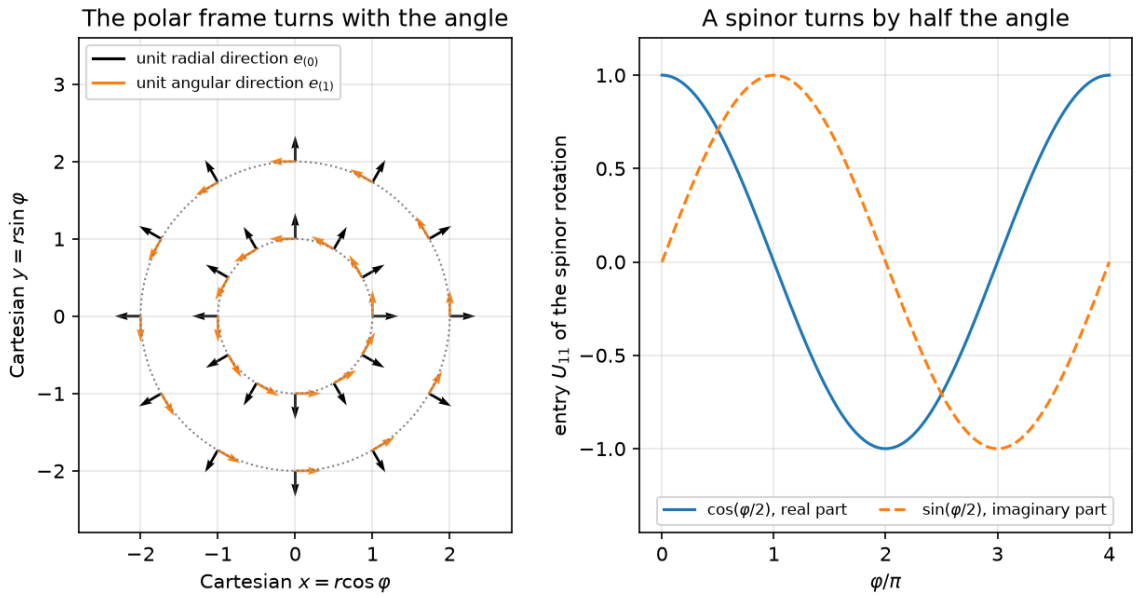

Figure 182: Warm-up in the flat plane. Left: the unit radial direction (black) and the unit angular direction (orange) of the polar frame at twelve angles on the circles $r = 1$ and $r = 2$, drawn in Cartesian coordinates x, y (pure numbers); the frame turns by the angle φ as one goes around, and the spin connection $\omega_{\varphi 01} = -1$ records this rate. Right: the entry $U_{11} = \cos(\varphi/2) + i\sin(\varphi/2)$ of the spinor rotation U that carries the Cartesian frame into the polar frame (its inverse U^{-1} removes the connection), real part (solid) and imaginary part (dashed), for φ from 0 to 4π; at $\varphi = 2\pi$ the spinor rotation is -1, and only at 4π is it $+1$ again. (Notebook 06a, figure 1.)

8. The author's metric and its diagonal vielbein

The next cell makes the symbols of the author's metric: the coordinates $x0, \dots, x7$ (real), the constant $H > 0$, the two functions $a_4(x_4)$ and $b_4(x_4) > 0$ (unknown functions: every result below holds for EVERY a_4 and b_4), and $z = 6Hx_0$. It writes the eight factors f_a of the diagonal vielbein and checks four things: that $\eta_{aa} f_a^2 = g_{aa}$ reproduces the author's metric with b_4 as recorded in `Revision/metric_b4/results/metric-b4.json` (key `metricDiagonal`); that at $b_4 = 1$ it is the metric of the record `Revision/theory/field-theory.json` (key `metric`) and the factors are its `vielbein_diagonal`; and that $\sqrt{|\det g|} = f_0 f_1 \cdots f_7 = b_4^{3/2}\cos z$ (key `sqrtAbsDetG` of `metric-b4.json`). The last fact has a meaning: the factors e^{3a_4} of the inflating 3-space and e^{-3a_4} of the deflating extra times cancel in the volume, so the 7-volume of a slice changes with the time $x4$ only through $b_4^{3/2}$, and not at all when b_4 is constant.

```
The next cell draws the eight vielbein factors. The left panel shows how they
depend on the time $x4$ at the fixed hidden angle $z = \pi/4$, for one illustrative
history $a_4(x_4) = x_4$, $b_4 = 1$ in units in which $H = 1$ (an illustration
only: the results of this notebook hold for every $a_4$ and $b_4$). On a
logarithmic vertical axis the exponential factors are straight lines: the 3-space
factor $e^{a_4}s$ rises, the extra-time factor $e^{-a_4}b_4^{1/2}s$ falls at the
same rate, and their product is constant (a $b_4$ different from 1 would multiply
the falling line by $b_4^{1/2}$). The right panel shows the dependence on $z$ at
$x_4 = 0$: the factor $s = \sin^{1/6} z$ of the six warped directions, the
hidden-direction factor $\cot z$ and the volume factor $\sqrt{|\det g|} = \cos z$
(at $b_4 = 1$).
```

## 9. The Christoffel symbols of the author's metric

The next cell computes all Christoffel symbols with the general function, counts
the independent nonzero ones (those with $m \le n$; the records count 25) and
compares each of them with the list 'christoffel_nonzero' of the record with
$b_4$, and, at $b_4 = 1$, with the same list of the record of $b_4 = 1$. In these
lists an entry $\{l, m, n, \text{value}\}$ means $\Gamma^{l}{}_{mn} = $ value, with
the directions numbered from 1 in the order $x0, \dots, x7$ (the number 1 is $x0$,
5 is $x4$); Python counts from 0, so 1 is subtracted. The cell prints five symbols.
One of them is $\Gamma^{x1}{}_{x1\,x4} = a_4'$: moving forward in time, a 3-space
direction grows at the rate $a_4'$; its partner $\Gamma^{x5}{}_{x4\,x5} = -a_4' +
b_4'/(2b_4)$ says that an extra-time direction shrinks at the rate $a_4'$ and is
stretched by a changing $b_4$.
```

## 10. The canonical spin connection

The next cell computes $\omega_{\mu ab}$ with the general function and checks:
```

```
1. the vielbein postulate $\partial_\mu e^a{}_\nu - \sum_\lambda
   \Gamma^\lambda{}_{\mu\nu}e^a{}_\lambda + \sum_b \omega_\mu{}^a{}_b e^b{}_\nu = 0$
   in all $8 \cdot 8 \cdot 8 = 512$ components (here $\omega_\mu{}^a{}_b =
   \eta_{aa}\omega_{\mu ab}$, because $\eta_{aa}^2 = 1$);
2. the antisymmetry $\omega_{\mu ab} = -\omega_{\mu ba}$ (all 512 triples);
3. that exactly 12 components with $a < b$ are nonzero and equal the list
   ‘omega_nonzero‘ (entries $\{\mu, a, b, \text{value}\}$, numbered from 1 as for
   the Christoffel symbols) of the record with $b_4$, and at $b_4 = 1$ that of the
   record of $b_4 = 1$;
4. that every nonzero component is a rate times a factor that never vanishes for
   $0 < z < \pi/2$: the rate is $a_4'$ (3-space), $a_4' - b_4'/(2b_4)$ (the extra
   times) or $H$ (the hidden direction), and the factor is $\pm e^{a_4}s$ or
   $\pm e^{-a_4}b_4^{1/2}s$. So the part of the spin connection made by the time
   dependence vanishes only if $a_4$ and $b_4$ are constant, and the part made by
   the hidden direction never vanishes for $H > 0$.
```

In [11]:

```

The next cell draws two of the eight 8 x 8 arrays $\omega_{\mu ab}$ at the sample
point: for $\mu = x1$ (an inflating 3-space direction) and for $\mu = x5$ (a
deflating extra time). Each array is antisymmetric: the square $(a, b)$ has the
opposite colour of the square $(b, a)$, and the diagonal is white. For $\mu = x1$
the frame direction $x1$ turns towards the time $x4$ (rate $a_4' e^{a_4}s$) and
towards the hidden direction $x0$ (rate $H e^{a_4}s$); for $\mu = x5$ the signs are
reversed, because the extra times shrink while 3-space grows (at the sample point
$a_4' - b_4'/(2b_4) = 1/4$ is still positive).

## 11. The spinor connection $\Omega_\mu$ and the covariant constancy of the gammas

The next cell builds the eight 16 x 16 matrices $\Omega_\mu$ and the curved gammas
$\gamma^\mu = \gamma^a/f_a$ (no sum) and checks:

1. $\Omega_{x4} = \Omega_{x0} = 0$: no frame direction turns when one moves along
   the time or along the hidden direction;
2. the defining property of the spinor connection, $[\Omega_\mu, \gamma^a] =
   -\sum_b \omega_\mu{}^a{}_b \gamma^b$ for all 64 pairs $(\mu, a)$: commuting
   with $\Omega_\mu$ turns the gammas exactly as $\omega_\mu$ turns the frame;
3. the covariant constancy of the curved gammas, $D_\mu\gamma^\nu = \partial_\mu
   \gamma^\nu + \sum_\lambda\Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu,
   \gamma^\nu] = 0$ for all 64 pairs $(\mu, \nu)$, which is the vielbein postulate
   written with gammas.
```

```

Text cell:

```
Each $\Omega_\mu$ is a combination of two of the matrices $S^{ab}$:
$\Omega_{x1} = e^{a_4}s\,(a_4' S^{x1\,x4} + H S^{x1\,x0})$ and $\Omega_{x5} =
-e^{-a_4}b_4^{1/2}s\,\big((a_4' - \frac{b_4'}{2b_4}) S^{x4\,x5} + H S^{x5\,x0}\big)$.
The author's gammas are real, the
four space-like ones are symmetric matrices and the four time-like ones are
antisymmetric. Because of this, $S^{ab} = \frac12\gamma^a\gamma^b$ ($a \ne b$)
is a SYMMETRIC matrix when one of $a, b$ is space-like and the other time-like
(a **boost**, 16 pairs), and an ANTISYMMETRIC matrix when both are of the same
kind (a **rotation**, 12 pairs). The next cell checks this for all 28 pairs and
then draws $\Omega_{x1}$ and $\Omega_{x5}$ as 16 x 16 heat maps at the sample
point. In $\Omega_{x1}$ the $a_4'$ part is a boost ($x1$ with the time $x4$,
symmetric) and the $H$ part a rotation ($x1$ with $x0$, antisymmetric); in
$\Omega_{x5}$ it is the other way round ($x4$ with $x5$ is a rotation of two
time-like directions, $x5$ with $x0$ a boost).

## 12. The contraction $\gamma^\mu\Omega_\mu$, direction by direction

The field equation contains $\gamma^\mu D_\mu\Psi = \gamma^\mu\partial_\mu\Psi +
\gamma^\mu\Omega_\mu\Psi$, so the spin connection enters it only through the
16 x 16 matrix $\gamma^\mu\Omega_\mu$ (summed over $\mu$). The next cell computes
each term $\gamma^\mu\Omega_\mu$ (no sum) separately and writes it as
$\alpha_\mu\gamma^{(x4)} + \beta_\mu\gamma^{(x0)}$. The numbers $\alpha_\mu$ and
$\beta_\mu$ are found with traces: for two different gammas
$\mathrm{tr}(\gamma^a\gamma^b) = 0$, while $\mathrm{tr}(\gamma^{(x4)}
\gamma^{(x4)}) = -16$ and $\mathrm{tr}(\gamma^{(x0)}\gamma^{(x0)}) = +16$, so
$\alpha_\mu = -\mathrm{tr}(M\gamma^{(x4)})/16$ and $\beta_\mu =
\mathrm{tr}(M\gamma^{(x0)})/16$ for $M = \gamma^\mu\Omega_\mu$; the cell then
checks that $M - \alpha_\mu\gamma^{(x4)} - \beta_\mu\gamma^{(x0)}$ is the zero
matrix. It compares the table with the predicted values ($\alpha = a_4'/2$ for
$x1, x2, x3$, $\alpha = -a_4'/2 + b_4'/(4b_4)$ for $x5, x6, x7$, $\beta = H/2$ for
these six directions, and zero for $x0$ and $x4$; the record with $b_4$ checks the
same table), at $b_4 = 1$ with the record's table 'gammaOmega_per_direction', and
the sum with the record's 'gammaOmega_total'.
```

Text cell:

```
The next cell draws the table of the previous cell as three bar charts, one bar for
each direction $\mu$. The coefficient $\alpha_\mu$ of $\gamma^{(x4)}$ is the sum of
a part proportional to $a_4'$ and a part proportional to $b_4'/b_4$; the left chart
shows the first in units of $a_4'$, the middle chart the second in units of
$b_4'/b_4$, and the right chart the coefficient $\beta_\mu$ of $\gamma^{(x0)}$ in
units of $H$. The left bars cancel in pairs (three up, three down: total $0$); the
middle bars come only from the extra times (three times $\frac14$: total
$\frac34$); the right bars all point the same way (six times $\frac12$: total $3$).
```

```

Text cell:

The next cell shows the same sum as pictures of the 16 x 16 matrices at the sample point ($H = 1$, $a_4' = 1/2$, $b_4 = 1$, $b_4' = 1/2$): the sum of the three inflating terms, the sum of the three deflating terms, the total $\gamma^\mu\Omega_\mu$, and $3H\gamma^{(x0)} + \frac34(b_4'/b_4)\gamma^{(x4)}$. The first two pictures contain the $\gamma^{(x4)}$ pattern with opposite colours (entries $\frac32 a_4' = 0.75$ in the first, $\frac32 a_4' - \frac34 b_4'/b_4 = 0.375$ in the second), on top of the same $\gamma^{(x0)}$ pattern (entries $\frac32 H = 1.5$); in the total only the $\gamma^{(x4)}$ entries $\frac34 b_4'/b_4 = 0.375$ remain next to $3H\gamma^{(x0)}$, and the total is the picture of the predicted matrix. The author's $\gamma^{(x0)}$ has the 8 x 8 identity matrix in its upper-right and lower-left blocks and zeros elsewhere: it maps the first eight spinor components onto the last eight and back, so $3H\gamma^{(x0)}$ shows the value 3 on two diagonal lines. The cell first checks the block form of all eight gammas against the record's list 'field_equation_blocks': each entry $\{xa, \bar t, t\}$ says that $\gamma^{(xa)}$ has the 8 x 8 block $\bar t$ in its upper-right corner, the block t in its lower-left corner and zeros in the two diagonal blocks. The record is written with curly brackets; replacing them by square brackets turns each entry into JSON, which 'json.loads' reads.

## 13. Why $a_4$ drops out and $b_4$ does not: the divergence form

Two facts explain the result without computing all of $\Omega_\mu$.

**Fact 1.** For each $\mu$ separately, $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu
= 0$ (no sum). Now sum the covariant constancy $D_\mu\gamma^\nu = 0$ over
$\mu = \nu$: $\sum_\mu\partial_\mu\gamma^\mu + \sum_{\mu,\lambda}
\Gamma^\mu{}_{\mu\lambda}\gamma^\lambda + \sum_\mu(\Omega_\mu\gamma^\mu -
\gamma^\mu\Omega_\mu) = 0$. The standard contraction $\sum_\mu
\Gamma^\mu{}_{\mu\lambda} = \partial_\lambda \ln\sqrt{|g|}$ turns the first two sums
into $\frac{1}{\sqrt{|g|}}\sum_\mu\partial_\mu(\sqrt{|g|}\,\gamma^\mu)$ (product
rule), and Fact 1 turns the last sum into $-2\sum_\mu\gamma^\mu\Omega_\mu$. Solving
for the contraction gives

$$\gamma^\mu\Omega_\mu = \frac{1}{2\sqrt{|g|}}\sum_\mu \partial_\mu\big(\sqrt{|g|}\,
\gamma^\mu\big) .$$

**Fact 2.** For the diagonal vielbein, $\sqrt{|g|}\gamma^\mu = \big(\prod_{c \ne
\mu} f_c\big)\gamma^{(\mu)}$, because $\sqrt{|g|} = \prod_c f_c$ and $\gamma^\mu =
\gamma^{(\mu)}/f_\mu$. Now $\prod_{c \ne x4} f_c = b_4^{3/2}\cos z$ (the factors
$e^{3a_4}$ and $e^{-3a_4}$ cancel, the three factors $b_4^{1/2}$ of the extra times
remain), so the time direction contributes $\frac{1}{2b_4^{3/2}\cos z}\,
\partial_{x4}(b_4^{3/2}\cos z) = \frac34\,\frac{b_4'}{b_4}$: nothing when $b_4$ is
constant. And $\prod_{c \ne x0} f_c = b_4^{3/2}\sin z$ gives
$\frac{1}{2b_4^{3/2}\cos z}\,\partial_{x0}(b_4^{3/2}\sin z) =
\frac{6H\cos z}{2\cos z} = 3H$. The other six products do not depend on their own
coordinate.

The next cell checks Fact 1 for every $\mu$, the divergence form, and the eight
products of Fact 2.
```

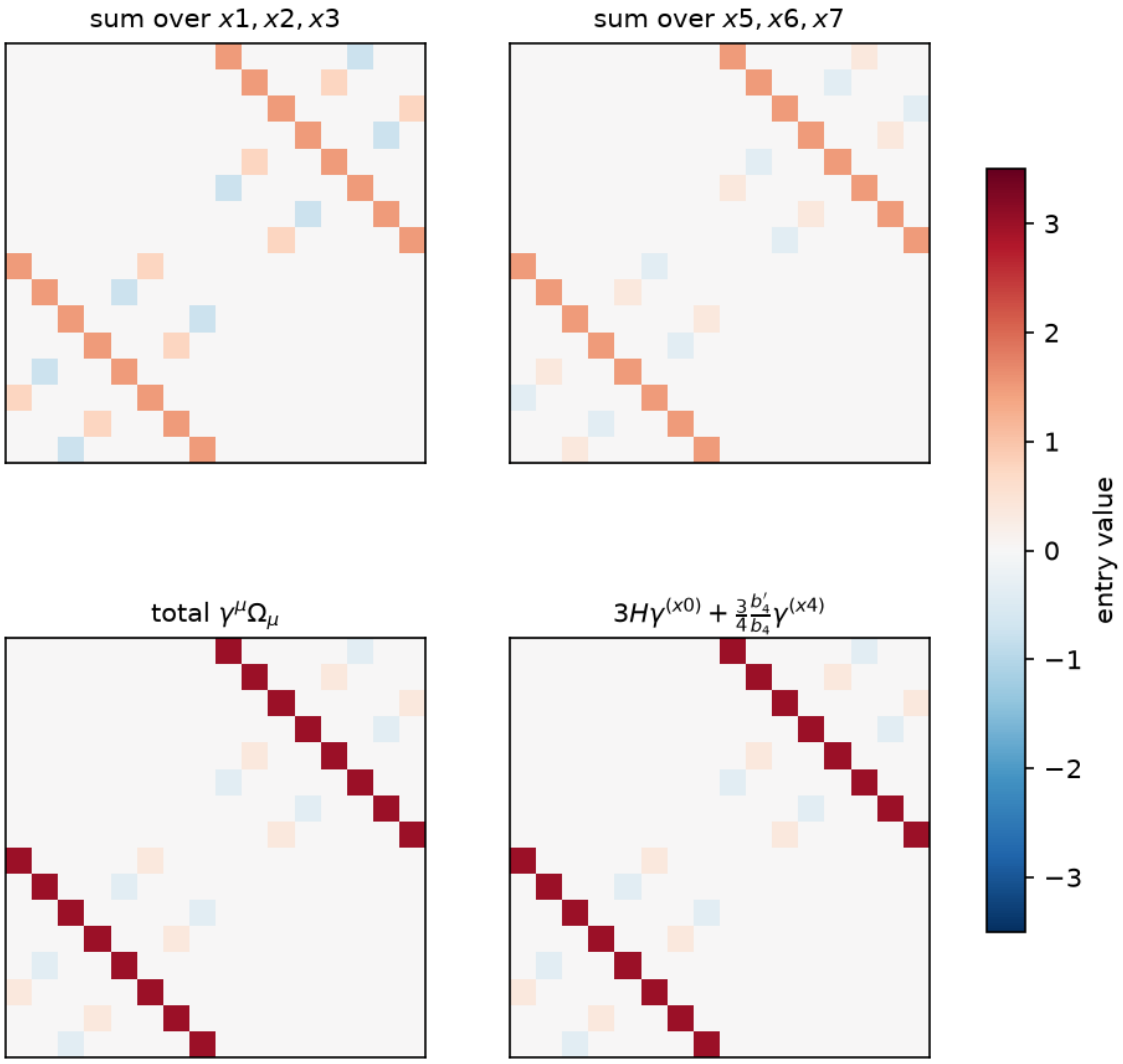

Figure 188: The sum as pictures of 16 x 16 matrices at the sample point $H = 1$, $z = \pi/4$, $a_4 = 1/2$, $a_4' = 1/2$, $b_4 = 1$, $b_4' = 1/2$ (red positive, blue negative, white zero; colour scale from -3.5 to 3.5). Top left: the sum of the three inflating terms $\gamma^{\mu}\Omega_{\mu}$, $\mu = x1, x2, x3$; top right: the sum of the three deflating terms, $\mu = x5, x6, x7$; their $\gamma^{(x4)}$ parts have opposite signs and sizes 0.75 and 0.375. Bottom left: the total over all eight directions; bottom right: $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$. The two bottom pictures are identical; for a constant b_4 the faint $\gamma^{(x4)}$ entries would vanish. (Notebook 06a, figure 7.)

Text cell:

```
The next cell checks Fact 2 with numbers instead of symbols, as a student would with
a calculator. For the hidden direction it computes the derivative of
$b_4^{3/2}\sin z$ with respect to $x_0$ by a **central difference**,
$\big(F(x_0 + h) - F(x_0 - h)\big)/(2h)$ with the small step $h = 10^{-5}$, divides
by $2b_4^{3/2}\cos z$ and plots the result over the whole range of $z$ (with
$H = 1$; $b_4$ does not depend on $x_0$ and cancels). For the time direction it
takes one illustrative history, $b_4(x_4) = 1 + \frac12\sin x_4$ (positive, an
illustration only), computes the derivative of $b_4^{3/2}\cos z$ with respect to
$x_4$ in the same way, divides by $2b_4^{3/2}\cos z$ ($\cos z$ cancels) and
compares with the exact $\frac34 b_4'/b_4$; for $b_4 = 1$ the coefficient is
```

```
exactly $0$, drawn as a line for comparison. The differences from the exact values
are of the size $h^2$ times third derivatives (about $10^{-9}$), far below the
check limit $10^{-6}$.
```

In [19]:

```

## 14. The covariant derivative of a spinor and the Dirac operator written out

The next cell takes a completely general spinor field: 16 unknown functions
$\psi_1, \dots, \psi_{16}$ of all eight coordinates. It computes the covariant
derivatives $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and the Dirac operator
$\gamma^\mu D_\mu\Psi$, and checks that

$$\gamma^\mu D_\mu\Psi = \sum_a \frac{1}{f_a}\gamma^{(a)}\partial_a\Psi +
3H\gamma^{(x0)}\Psi + \tfrac34\,\frac{b_4'}{b_4}\,\gamma^{(x4)}\Psi ,$$

that is, with the factors written out, $\tan z\,\gamma^{(x0)}\partial_0\Psi +
e^{-a_4}s^{-1}(\gamma^{(x1)}\partial_1 + \gamma^{(x2)}\partial_2 +
\gamma^{(x3)}\partial_3)\Psi + \gamma^{(x4)}\partial_4\Psi +
e^{a_4}b_4^{-1/2}s^{-1}(\gamma^{(x5)}\partial_5 + \gamma^{(x6)}\partial_6 +
\gamma^{(x7)}\partial_7)\Psi + 3H\gamma^{(x0)}\Psi +
\frac34(b_4'/b_4)\gamma^{(x4)}\Psi$. It then compares all 16 components with the
16 component equations of the record with $b_4$, and at $b_4 = 1$ with those of
the record of $b_4 = 1$ (‘field_equation_components‘; their right-hand side
$V\Psi_A$, $V = m + U'(S)$, is not needed here).

Finally it checks when the term $M\Psi$, $M = 3H\gamma^{(x0)} +
\frac34(b_4'/b_4)\gamma^{(x4)}$, can vanish for a field that is not zero. Since
$(\gamma^{(x0)})^2 = 1$, $(\gamma^{(x4)})^2 = -1$ and the two anticommute,
$MM = \big(9H^2 - \frac{9}{16}(b_4'/b_4)^2\big)\,1$. When the number in front of
$1$ is not zero, $M\Psi = 0$ gives $\Psi = 0$ (multiply by $M$ and divide by that
number): this is so for every constant $b_4$, where $M = 3H\gamma^{(x0)}$, and the
WolframScript report ‘wolfram-field-theory.json‘ records the statement for both
fields at $b_4 = 1$ (checks ‘nontriviality_1_dirac16complex‘ and
‘nontriviality_2_dirac16complex00‘). Where $|b_4'/b_4| = 4H$, however, $MM = 0$:
the cell computes that $\gamma^{(x0)} \pm \gamma^{(x4)}$ has rank 8, so there $M$
sends an 8-dimensional set of nonzero fields to zero (the record with $b_4$ checks
the same, check ‘gravity_term_square_b4‘).
```

The deflation does not appear in $\gamma^\mu\Omega_\mu$, but it does appear in the
Dirac operator: through the factors $1/f_a$ in front of the derivatives. The next
cell draws these factors. On the left, versus the time for the illustrative
history $a_4 = x_4$, $b_4 = 1$ (with $H = 1$, $z = \pi/4$): as 3-space inflates, the
3-space derivatives are weighted less and less ($e^{-a_4}/s$), and as the extra
times deflate, the extra-time derivatives are weighted more and more
($e^{a_4}b_4^{-1/2}/s$). On the right, versus $z$ at $x_4 = 0$: the
hidden-direction factor $\tan z$ and the common factor $1/s$ of the six warped
directions.

## 15. The negative control: extra times that INFLATE

Is the cancellation of the $a_4'$ terms an accident of the algebra, or does it come
from the deflation? The control answers this. The next cell repeats the whole
computation (Christoffel symbols, spin connection, spinor connection, curved
gammas) for a changed metric in which the extra times inflate like 3-space,
$g_{tt} = -e^{+2a_4}\sin^{1/3}z$ for $t = x5, x6, x7$, with vielbein factors
$e^{+a_4}s$ (at $b_4 = 1$, as in the lead's record, so that only the deflation is
changed). If the deflation is the reason, a term with $a_4'$ must survive. The
record of the lead's independent check finds $3a_4'\gamma^{(x4)}$; the cell checks
that it gets the same, and that the hidden term $3H\gamma^{(x0)}$ is unchanged.
```

16. The last checks

Most results of this notebook are recorded several times in the Revision record, by verifiers that share no code: for the metric with b_4 the sympy checker (report ‘python-field-theory-b4.json‘) and the WolframScript checker (‘wolfram-field-theory-b4.json‘); for the background $b_4 = 1$ the sympy checker (‘python-field-theory.json‘), the WolframScript checker (‘wolfram-field-theory.json‘) and the lead’s independent check (‘emt-divergence-and-spin-connection.json‘). Each PASS line above names one of them. The last cell lists every check of these five reports that states a result reproduced here and checks that each is recorded as passed (so the record this notebook reproduces is itself a passing record). Then it checks that all ten figure files exist in the folder Revision/textbook/figures, and prints the number of checks that passed.

## 17. What this notebook showed

- In the flat plane in polar coordinates the spin connection is not zero
  ($\omega_{\varphi 01} = -1$, $\gamma^\mu\Omega_\mu = \sigma_1/(2r)$), but its
  curvature is zero and a spinor rotation removes it: in flat space the spin
  connection only records how the chosen frame turns.
- For the author's metric the diagonal vielbein $f = (\cot z,\ e^{a_4}s\
  (\times 3),\ 1,\ e^{-a_4}b_4^{1/2}s\ (\times 3))$ gives the metric back, and
  $\sqrt{|\det g|} = b_4^{3/2}\cos z$ depends on the time only through $b_4$
  (PROVED, exact; reproduces the records with $b_4$ and at $b_4 = 1$).
- The metric has 25 independent nonzero Christoffel symbols, and the canonical spin
  connection has 12 independent nonzero components $\omega_{\mu ab}$, each equal to
  a rate ($a_4'$, $a_4' - b_4'/(2b_4)$ or $H$) times a factor that never vanishes;
  the vielbein postulate (512 equations), the antisymmetry and the covariant
  constancy of the gammas (64 matrix equations) hold exactly (PROVED; reproduces the
  records).
- $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \frac34(b_4'/b_4)\gamma^{(x4)}$ exactly,
  for every $H > 0$ and all functions $a_4(x_4)$, $b_4(x_4) > 0$ (PROVED; reproduces
  the records with $b_4$, and at $b_4 = 1$ the Python, Wolfram and lead records):
  the time-direction terms $+\frac32 a_4'$ of the three inflating directions and
  $-\frac32 a_4'$ of the three deflating extra times cancel, the extra times leave
  $\frac34 b_4'/b_4$, and the six hidden terms $\frac12 H$ add up to $3H$. The
  reason is the divergence form: the density $\sqrt{|g|}\,e_{(x4)}{}^{x4} =
  b_4^{3/2}\cos z$ changes with the time only through $b_4$. For a constant $b_4$,
  as on the backgrounds of this book, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)}$.
- The Dirac operator is $\sum_a f_a^{-1}\gamma^{(a)}\partial_a + 3H\gamma^{(x0)} +
  \frac34(b_4'/b_4)\gamma^{(x4)}$; all 16 component equations equal the records.
  The deflation enters the field equation through the factors $e^{\mp a_4}$ in
  front of the derivatives, not through $\gamma^\mu\Omega_\mu$.
- The term vanishes for a nonzero field only where $|b_4'/b_4| = 4H$ (never for a
  constant $b_4$), because its square is $(9H^2 - \frac{9}{16}(b_4'/b_4)^2)\,1$.
- NEGATIVE CONTROL (at $b_4 = 1$): with inflating extra times the term
  $3a_4'\gamma^{(x4)}$ survives (reproduces the lead's record): the cancellation
  of the $a_4'$ terms is caused by the deflation.
- Scope (stated by the record and shown in Notebook 06b): the value of
  $\gamma^\mu\Omega_\mu$ belongs to the diagonal vielbein; it changes in a boosted
  vielbein and is removed by a rescaling of the field, while the curvature of the
  metric can be removed by nothing.
```

6.14 Line-by-line walk-through of Notebook 06a

The notebook has 24 code cells, In [1] to In [24]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted and then explained. A line that starts with `#` is a **comment**, which Python skips; it is there for the reader. In a quoted figure cell a line `...` stands for the remaining lines of a long caption; every caption is printed in full under its figure in Section 6.13, and a paragraph "What Figure 06a.k shows" after the code says what to look for and why. The words of the notebook are those of its section 3 (Section 6.13), which Sections 6.2 to 6.7 defined.

In [1], the set-up cell. Its first part is the complete run instructions of Section 6.12 once more, as comment lines, so that the notebook file carries its own instructions. The code starts below the line that announces THE SET-UP. The set-up code is the same in every notebook of the book except for one line, the notebook's name; it is explained here once, and the walk-throughs of Notebooks 06b and 06c refer back to this explanation.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json` reads and writes JSON files (text files that store names, lists and numbers), `os` reads settings of the computer, `textwrap` breaks long lines, and `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on Windows, macOS and Linux. The plotting package matplotlib is loaded together with its drawing functions under the short name `plt`, and `Image` and `display` come from IPython, the part of Jupyter that runs Python; together they show a saved picture below a cell.

```
NOTEBOOK_ID = "06a"  # this notebook: chapter 06, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"06a"`. It is the only line of the set-up code that differs from notebook to notebook; the figure files and the last printed line are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
```

```
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. The text in triple quotes below the `def` line is its **docstring**, a description that Python stores and does not execute. `Path.cwd()` is the folder in which the notebook runs and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with all of them. The `for` loop takes these folders one after the other; `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If no folder holds it, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The function is called and its result named `REPO`. It is never printed: it differs from computer to computer, while the printed output of a notebook must not. `os.environ` holds the **environment variables** of the computer (named texts that a program receives when it starts); `.get(name, defau lt)` returns the value of `TEXTBOOK_OUTPUT_ROOT` when it is set and the repository folder otherwise. When you run the notebook the variable is not set, so files are written into the repository; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` is the full path of a repository file, used to READ a Revision record. `output_file("Revision/...")` is the full path at which a file is WRITTEN; `path.par ent.mkdir(parents=True, exist_ok=True)` first creates its folder (and any missing folder above it) and does nothing if the folder exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of the book: `str(text)` turns any value into text, and `textwrap.fill` breaks it at blanks; every line after the first starts with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings of matplotlib, so that the figures are the same on every computer whatever personal settings it has. `plt.rcParams.update({...})` then sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid behind the curves. The braces make a **dictionary**, a collection of pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: each name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/06a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary `{}` and a line end into the captions file; `encoding="utf-8"` fixes how the letters are stored, and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` is called once for every figure. `FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)` returns the number already stored for this figure name, or stores and returns

one more than the number of figures so far; so the figures are numbered 1, 2, 3, and a cell that is run twice keeps its number. The file name joins the notebook id, the number and the name, for example `06a_1_polar_frame_and_spin_rotation.png`. `fig.savefig` writes the picture as a PNG file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write exactly the same bytes. `plt.close(fig)` removes the figure from memory (Jupyter would otherwise draw it a second time). The caption is stored, and the whole dictionary of captions is written to the captions file (`json.dumps` turns it into JSON text with sorted keys). `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list**, an ordered collection written with square brackets. `check` is the function behind every check of the book. `condition` is `True` or `False`; if it is false, `raise AssertionError(...)` stops the notebook with an error that names the check (Python's own statement `assert` is not used, because Python started with the option `-O` would skip it). If it is true, the name is appended to `PASSED` and the line PASS name is printed; when the optional argument `record` names a Revision record, a second line says which record file and which check the result reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT. `all_checks_passed` prints the last line of the notebook with the number of checks that passed (`len` is the length of a list). The final statement prints the single output line of In [1].

In [2], the gammas from the record.

```
import sys  # the Python system module (here: the stream of printed text)

# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
```

`sys` is the Python module that holds, among other things, `sys.stdout`, the channel through which everything printed travels. Inside Jupyter this channel collects printed text and sends it to the screen in pieces, about every 0.2 seconds. The book's checking tool reads each PASS line together with its "reproduces" line, so the pieces must be the same in every run. `hasattr(sys.stdout, "flush_interval")` is true only inside Jupyter (outside it the channel has no such setting), and then the interval is set to 600 seconds: the text of a cell is sent in one piece when the cell ends, or just before a figure is shown. This changes no result.

```
import numpy as np  # arrays of decimal numbers (only for the plots)
import sympy as sp  # exact algebra and calculus with symbols
```

numpy (short name `np`) computes with decimal numbers and is used only for the plots; sympy (short name `sp`) computes exactly with symbols, fractions and functions, and does all the mathematics of the notebook.

```
GAMMA_FILE = "Revision/algebra/gammas.json"  # a Revision record (read only)
fixture = json.loads(repository_file(GAMMA_FILE).read_text(encoding="utf-8"))
NAMES = fixture["coordinates"]  # ["x0", ..., "x7"], the names of the directions
ETA = fixture["eta"]  # the frame metric: +1 space-like, -1 time-like
```

`GAMMA_FILE` names the Revision record of the gammas. `read_text` reads the file as text and `json.loads` turns the text into Python objects: `fixture` is a dictionary whose keys are the names stored in the record. `fixture["coordinates"]` is the list `["x0", ..., "x7"]`, and `fixture["eta"]` the list of the diagonal entries of η.

```
# Each gamma is stored as 16 rows of 16 whole numbers; sp.Matrix makes it an exact
# sympy matrix.  gamma[a] is the gamma of the direction NAMES[a].
gamma = [sp.Matrix(rows) for rows in fixture["gamma"]]
I16 = sp.eye(16)  # the 16 x 16 identity matrix
Z16 = sp.zeros(16, 16)  # the 16 x 16 zero matrix
say(f"directions: {NAMES}")
say(f"eta (frame metric): {ETA}")
```

Each gamma is stored as 16 rows of 16 whole numbers; `sp.Matrix(rows)` turns it into an exact sympy matrix. The **list comprehension** `[... for rows in ...]` builds the list of the eight matrices in one line, so `gamma[0]` is $\gamma^{(x0)}$, `gamma[1]` is $\gamma^{(x1)}$ and `gamma[4]` is $\gamma^{(x4)}$ (Python counts from 0, and the record lists the gammas in the order $x0, \ldots, x7$). `sp.eye(16)` is the identity matrix and `sp.zeros(16, 16)` the zero matrix. The two `say` lines print the directions and the signs of η, the first two output lines.

```
# The Clifford relation for all 8 x 8 = 64 pairs (a, b): the anticommutator is
# 2 eta_aa times the identity when a = b and the zero matrix when a and b differ.
clifford = all(gamma[a] * gamma[b] + gamma[b] * gamma[a]
               == (2 * ETA[a] if a == b else 0) * I16
               for a in range(8) for b in range(8))
check(clifford, "the 64 Clifford relations of the author's gammas",
      record="Revision/theory/reports/python-field-theory.json, "
             "check clifford_relations")
```

`all(... for a in range(8) for b in range(8))` is true when the expression is true for every one of the $8 \times 8 = 64$ pairs; `range(8)` is the list $0, 1, \ldots, 7$. For each pair the left side is the anticommutator $\gamma^a\gamma^b + \gamma^b\gamma^a$ (with sympy matrices `*` is the matrix product) and the right side is $2\eta_{aa}$ times the identity when $a = b$ and the zero matrix otherwise (`x if condition else y` is `x` when the condition holds and `y` otherwise; `0 * I16` is the zero matrix). `==` compares two sympy matrices entry by entry, exactly. The check prints PASS and the record it reproduces.

```
# eight matrices, each with 16 rows and 16 columns, and every entry a real number
check(len(gamma) == 8 and all(matrix.shape == (16, 16) for matrix in gamma)
      and all(entry.is_real for matrix in gamma for entry in matrix),
      "the eight gammas are 16 x 16 matrices with real entries",
      record="Revision/theory/reports/python-field-theory.json, check gammas_real")
```

The second check requires eight matrices, each of shape 16 by 16, and every entry real (`entry.is_real` is true for a whole number). `and` is true only when all its parts are true.

```
# S[a][b] = (1/4)(gamma^a gamma^b - gamma^b gamma^a), for all 64 pairs (a, b).
S = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
     for a in range(8)]
```

`S[a][b]` is the generator $S^{ab} = \frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$ for all 64 ordered pairs, built with a nested list comprehension: for each `a` a list over `b`. The cell prints the two lines of the directions and of η, and two PASS lines with their records.

In [3], the helpers and the records.

```
from sympy.parsing.mathematica import parse_mathematica  # reads Wolfram notation
```

`parse_mathematica` is sympy's reader of formulas written in the notation of the Wolfram Language, the notation in which the records `Revision/theory/field-theory.json` and `Revision/theory/field-theory-b4.json` store their formulas.

```
def is_zero(expr):
    """True when expr is exactly zero for all values of its symbols."""
    expr = sp.sympify(expr)
    if expr == 0:
        return True
    # Fast route: sin, cos, tan, ... written through exp, multiplied out, cancelled.
    if sp.cancel(sp.expand(expr.rewrite(sp.exp))) == 0:
        return True
    return sp.simplify(expr) == 0  # the slower general route
```

`is_zero(expr)` decides exactly whether an expression is zero for all values of its symbols. `sp.sympify` turns a plain number into a sympy number. If the expression is already the number 0 the answer is yes. Otherwise the fast route writes every sine, cosine and tangent through exponential functions (`rewrite(sp.exp)`; for example $\cos z = (e^{iz} + e^{-iz})/2$), multiplies everything out (`expand`) and cancels common factors of numerator and denominator (`cancel`); if that gives 0, the expression is zero. If not, the slower general `sp.simplify` decides. Both routes are exact transformations, so the function never calls a nonzero expression zero; at worst it fails to recognise a zero, and then a check fails visibly.

```
def matrix_is_zero(matrix):
    """True when every entry of the matrix is exactly zero."""
    return all(is_zero(entry) for entry in matrix)
```

`matrix_is_zero` applies `is_zero` to every entry of a matrix (a `for` over a sympy matrix runs through its entries).

```
def record_passed(path, name):
    """True when the Revision report at path records the check name as passed."""
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in data["checks"]:
        if entry["name"] == name:
            return entry["verdict"].upper() == "PASS"  # "PASS" or "pass"
    raise KeyError(f"{path} has no check {name}")
```

`record_passed(path, name)` reads a Revision report, a JSON file with a list `checks` whose entries have the keys `name`, `verdict` and `detail`, and returns `True` when the check `name` is recorded with the verdict PASS (`.upper()` writes the verdict in capitals, because one report writes PASS and another pass). If the report has no such check, `raise KeyError` stops the notebook: a misspelled check name can never pass silently.

```
def read_formulas(path):
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    return {item["key"]: item["wl"] for item in data["formulas"]}
```

`read_formulas(path)` reads a record that holds a list `formulas`, each with a key and the formula as Wolfram text (`wl`). The **dictionary comprehension** `{item["key"]: item["wl"] for item in ...}` builds the dictionary from key to text in one line.

```
THEORY_FILE = "Revision/theory/field-theory.json"  # the record at b4 = 1
THEORY_B4_FILE = "Revision/theory/field-theory-b4.json"  # the record with b4(x4)
FORMULAS = read_formulas(THEORY_FILE)
FORMULAS_B4 = read_formulas(THEORY_B4_FILE)
```

```
def wolfram_to_sympy(text, names):
    """A text in Wolfram notation as a sympy expression.  names maps the record's
    symbol names (texts) to the symbols and functions of this notebook."""
    # The record writes a4', a4'', a4(x4) and the same for b4 as Derivative[1][a4][x4],
```

```
    # Derivative[2][a4][x4], a4[x4], ...; give them short names before reading.
    for long_form, short_form in (("Derivative[1][a4][x4]", "a4p"),
                                  ("Derivative[2][a4][x4]", "a4pp"),
                                  ("Derivative[1][b4][x4]", "b4p"),
                                  ("Derivative[2][b4][x4]", "b4pp"),
                                  ("a4[x4]", "a4"), ("b4[x4]", "b4")):
        text = text.replace(long_form, short_form)
    expr = parse_mathematica(text)
    return expr.subs({sp.Symbol(name): value for name, value in names.items()},
                     simultaneous=True)
```

`FORMULAS` holds the formulas of the record of the metric at $b_4 = 1$ and `FORMULAS_B4` those of the record of the metric with $b_4(x_4)$. `wolfram_to_sympy(text, names)` turns a text in Wolfram notation into a sympy expression. The records write a_4', a_4'' and $a_4(x_4)$ as `Derivative[1][a4][x4]`, `Derivative[2][a4][x4]` and `a4[x4]`, and the same for b_4; the loop replaces them by the short names `a4p`, `a4pp`, `b4p`, `b4pp`, `a4` and `b4` (`text.replace(old, new)` replaces every occurrence; the derivatives come first, because they contain the text `a4[x4]`). `parse_mathematica` reads the text, and `.subs({...}, simultaneous=True)` replaces each plain symbol of the record by the symbol or function of the notebook that the dictionary `names` gives for it, all at the same time. `record_formula(key, names, formulas)` does this for one formula of a record; without the third argument it reads the record of $b_4 = 1$ (a **default value** of the argument).

```
REPORT_PY = "Revision/theory/reports/python-field-theory.json"
REPORT_WL = "Revision/theory/reports/wolfram-field-theory.json"
REPORT_PY_B4 = "Revision/theory/reports/python-field-theory-b4.json"
REPORT_WL_B4 = "Revision/theory/reports/wolfram-field-theory-b4.json"
REPORT_LEAD = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
METRIC_B4_FILE = "Revision/metric_b4/results/metric-b4.json"
say(f"{len(FORMULAS)} formulas read from {THEORY_FILE}")
say(f"{len(FORMULAS_B4)} formulas read from {THEORY_B4_FILE}")
```

Names for the five Revision reports that the notebook reproduces and for the record `metric-b4.json`, and two output lines: 32 formulas read from Revision/theory/field-theory.json and 8 formulas read from Revision/theory/field-theory-b4.json.

In [4], four general formulas as Python functions. The four functions work for any number of dimensions and any vielbein, so the same code serves the plane and the author's eight-dimensional metric.

```
def christoffel(g, coords):
    """Gam[l][m][n] = (1/2) sum_r g^lr (d_m g_rn + d_n g_rm - d_r g_mn)."""
    n = len(coords)
    g_inv = g.inv()  # the inverse metric g^lr
    Gam = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for l in range(n):
        for m in range(n):
            for k in range(m, n):  # Gamma^l_mk = Gamma^l_km: compute it once
                value = sum(g_inv[l, r] * (sp.diff(g[r, k], coords[m])
                                           + sp.diff(g[r, m], coords[k])
                                           - sp.diff(g[m, k], coords[r]))
```

```
                        for r in range(n) if g_inv[l, r] != 0) / 2
                value = sp.simplify(value)
                Gam[l][m][k] = value
                Gam[l][k][m] = value
    return Gam
```

`christoffel(g, coords)` computes $\Gamma^l{}_{mn}$ by the formula of Section 6.3. `g.inv()` is the inverse matrix g^{lr}. `Gam` starts as a three-level list of zeros (`[sp.Integer(0)] * n` is a list of `n` exact zeros). The loops run over all `l` and `m` and over `k` from `m` upwards only: since $\Gamma^l{}_{mk} = \Gamma^l{}_{km}$, each symmetric pair is computed once and stored in both places. `sp.diff(g[r, k], coords[m])` is the partial derivative $\partial_m g_{rk}$; the generator expression sums over `r`, skipping the entries where the inverse metric is zero (for a diagonal metric only `r = l` remains), and `/ 2` is the factor $\frac{1}{2}$. `sp.simplify` brings each symbol into a short form.

```
def spin_connection(e, Gam, coords, eta):
    """omega[mu][a][b] = omega_{mu ab} = eta_aa omega_mu^a_b, where
    omega_mu^a_b = sum_nu e^a_nu (d_mu e_b^nu + sum_lam Gam^nu_{mu lam} e_b^lam)."""
    n = len(coords)
    E = e.inv()  # E[nu, b] = e_b^nu, the inverse vielbein
    omega = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for mu in range(n):
        for a in range(n):
            for b in range(n):
                mixed = 0  # will become omega_mu^a_b
                for nu in range(n):
                    if e[a, nu] == 0:
                        continue  # this term is zero
                    inner = sp.diff(E[nu, b], coords[mu]) + sum(
                        Gam[nu][mu][lam] * E[lam, b] for lam in range(n))
                    mixed += e[a, nu] * inner
                omega[mu][a][b] = sp.simplify(eta[a] * mixed)  # lower the index a
    return omega
```

`spin_connection(e, Gam, coords, eta)` computes the canonical spin connection by the formula of Section 6.4 and lowers its first index. The vielbein is the matrix `e` with `e[a, mu]` $= e^a{}_\mu$ (row = frame index, column = coordinate index). Its inverse matrix `E = e.inv()` has `E[mu, a]` $= e_a{}^\mu$, because $\sum_\mu e^a{}_\mu e_b{}^\mu = \delta^a_b$ says exactly `e * E` $= 1$. For each μ, a, b the variable `mixed` collects $\sum_\nu e^a{}_\nu \big(\partial_\mu e_b{}^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda} e_b{}^\lambda\big)$, the mixed component $\omega_\mu{}^a{}_b$; `continue` skips the values of ν where $e^a{}_\nu = 0$, which contribute nothing. The last line multiplies by η_{aa} (lowering the index a) and simplifies, so the function returns `omega[mu][a][b]` $= \omega_{\mu ab}$.

```
def spinor_connection(omega, S):
    """Omega[mu] = (1/2) sum_{a,b} omega_{mu ab} S^ab = sum_{a<b} omega_{mu ab} S^ab."""
    n = len(omega)
    size = S[0][0].shape[0]  # 16 for the author's gammas, 2 in two dimensions
    Omega = []
    for mu in range(n):
        total = sp.zeros(size, size)
        for a in range(n):
            for b in range(a + 1, n):
```

```
                if omega[mu][a][b] != 0:
                    total += omega[mu][a][b] * S[a][b]
        Omega.append(total)
    return Omega
```

`spinor_connection(omega, S)` builds $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$ (Section 6.7 showed that the sum over $a < b$ uses up the factor $\frac{1}{2}$). `S[0][0].shape[0]` is the size of the matrices, 16 for the author's gammas and 2 in the plane. For each μ a zero matrix is filled with the terms whose coefficient is not zero, and the eight matrices are collected in the list `Omega`.

```
def curved_gammas(e, gammas):
    """gamma^mu = sum_a e_a^mu gamma^a for every coordinate mu."""
    E = e.inv()
    n = len(gammas)
    return [sum((E[mu, a] * gammas[a] for a in range(n)),
                sp.zeros(*gammas[0].shape)) for mu in range(n)]
```

`curved_gammas(e, gammas)` returns the list of the curved gammas $\gamma^\mu = \sum_a e_a{}^\mu \gamma^a$; `sum(..., sp.zeros(...))` adds the matrices starting from a zero matrix of the right shape (`*gammas[0].shape` passes the two numbers of the shape as two arguments).

```
say("defined: christoffel, spin_connection, spinor_connection, curved_gammas")
```

One output line names the four functions.

In [5], the warm-up in the polar plane (Section 6.5).

```
r, phi = sp.symbols("r phi", positive=True)  # polar coordinates, r > 0
sigma1 = sp.Matrix([[0, 1], [1, 0]])  # the three Pauli matrices
sigma2 = sp.Matrix([[0, -sp.I], [sp.I, 0]])
sigma3 = sp.Matrix([[1, 0], [0, -1]])
plane_gammas = [sigma1, sigma2]  # gamma^0 (radial), gamma^1 (angular)
plane_eta = [1, 1]
plane_S = [[(plane_gammas[a] * plane_gammas[b] - plane_gammas[b] * plane_gammas[a])
            / 4 for b in range(2)] for a in range(2)]
plane_g = sp.diag(1, r**2)  # ds^2 = dr^2 + r^2 dphi^2
plane_e = sp.diag(1, r)  # e^a_mu: unit radial and unit angular direction
```

`sp.symbols("r phi", positive=True)` makes two symbols that sympy treats as positive numbers, the polar coordinates r and φ. The three Pauli matrices are typed entry by entry (`sp.I` is the imaginary unit i). The plane has the two gammas σ_1 (radial) and σ_2 (angular), the frame metric $\eta = (1, 1)$, the generators `plane_S` built exactly as `S` in In [2], the metric $\mathrm{diag}(1, r^2)$ and the vielbein $\mathrm{diag}(1, r)$.

```
plane_Gam = christoffel(plane_g, [r, phi])
plane_omega = spin_connection(plane_e, plane_Gam, [r, phi], plane_eta)
plane_Omega = spinor_connection(plane_omega, plane_S)
plane_gup = curved_gammas(plane_e, plane_gammas)
plane_slash = sp.simplify(plane_gup[0] * plane_Omega[0] + plane_gup[1] * plane_Omega[1])
```

The four general functions are applied to the plane. `plane_slash` is $\gamma^r\Omega_r + \gamma^\varphi\Omega_\varphi$, the contraction, simplified.

```
say(f"Gamma^r_phiphi = {plane_Gam[0][1][1]},  Gamma^phi_rphi = {plane_Gam[1][0][1]}")
say(f"omega_phi01 = {plane_omega[1][0][1]},  omega_phi10 = {plane_omega[1][1][0]}")
say(f"Omega_phi = {plane_Omega[1].tolist()}")
say(f"gamma^mu Omega_mu = {plane_slash.tolist()}")
```

Four output lines print the results: ${\Gamma^r}_{\varphi\varphi} = -r$, ${\Gamma^\varphi}_{r\varphi} = 1/r$, $\omega_{\varphi 01} = -1$, $\omega_{\varphi 10} = 1$, Ω_φ as the nested list `[[-I/2, 0], [0, I/2]]` (`.tolist()` turns a matrix into a list of rows) and the contraction `[[0, 1/(2*r)], [1/(2*r), 0]]`, which is $\sigma_1/(2r)$. Index `[1]` is φ and `[0]` is r.

```
check(plane_Gam[0][1][1] == -r and plane_Gam[1][0][1] == 1 / r,
      "polar plane: Gamma^r_phiphi = -r and Gamma^phi_rphi = 1/r")
check(plane_omega[1][0][1] == -1 and plane_omega[1][1][0] == 1
      and plane_omega[0][0][1] == 0, "polar plane: omega_phi01 = -1, omega_r = 0")
check(plane_Omega[1] == -sp.I / 2 * sigma3 and plane_Omega[0] == sp.zeros(2, 2),
      "polar plane: Omega_phi = -(i/2) sigma3 and Omega_r = 0")
check(plane_slash == sigma1 / (2 * r), "polar plane: gamma^mu Omega_mu = sigma1/(2 r)")
```

Four checks compare the results with the hand computation of Section 6.5: the two Christoffel symbols; the two components of ω_φ and the vanishing of ω_r; $\Omega_\varphi = -\frac{i}{2}\sigma_3$ and $\Omega_r = 0$; and $\sum_\mu \gamma^\mu\Omega_\mu = \sigma_1/(2r)$.

```
F_rphi = (plane_Omega[1].diff(r) - plane_Omega[0].diff(phi)
          + plane_Omega[0] * plane_Omega[1] - plane_Omega[1] * plane_Omega[0])
U = sp.cos(phi / 2) * sp.eye(2) + sp.I * sp.sin(phi / 2) * sigma3  # spinor rotation
pure_gauge = -U.diff(phi) * U.inv() - plane_Omega[1]  # must be the zero matrix
removed = U.inv() * plane_Omega[1] * U - U.inv().diff(phi) * U  # frame change U^-1
check(F_rphi == sp.zeros(2, 2) and matrix_is_zero(pure_gauge)
      and matrix_is_zero(removed),
      "polar plane: flat (F_rphi = 0), Omega_phi = -(dU/dphi) U^-1, U^-1 removes it")
```

`F_rphi` is the curvature $\partial_r\Omega_\varphi - \partial_\varphi\Omega_r + [\Omega_r, \Omega_\varphi]$ (`.diff(r)` differentiates every entry). `U` is the spinor rotation $\cos\frac{\varphi}{2} + i\sin\frac{\varphi}{2}\,\sigma_3$, and `pure_gauge` is $-(\partial_\varphi U)U^{-1} - \Omega_\varphi$ (`U.inv()` is the inverse matrix): it vanishes when Ω_φ is what the rule $R\,\Omega R^{-1} - (\partial_\varphi R)R^{-1}$ of a change of frame makes from the connection 0 of the Cartesian frame with $R = U$. `removed` is that rule applied to Ω_φ with $R = U^{-1}$, whose inverse is U: $U^{-1}\Omega_\varphi U - (\partial_\varphi U^{-1})U$, the connection of the frame obtained by turning the polar frame back with U^{-1} (Section 6.5 worked it by hand). The fifth check requires all three to be zero: the plane is flat, its spin connection is only the turning of the frame, and the inverse rotation U^{-1} removes it. The cell prints five PASS lines.

In [6], figure 1.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.6))
angles = np.arange(12) * np.pi / 6  # 12 angles, 30 degrees apart
for radius in (1.0, 2.0):
    px, py = radius * np.cos(angles), radius * np.sin(angles)  # the points
    ax_left.quiver(px, py, np.cos(angles), np.sin(angles), color="black",
```

```
                angles="xy", scale_units="xy", scale=3.0, width=0.006)
    ax_left.quiver(px, py, -np.sin(angles), np.cos(angles), color="tab:orange",
                angles="xy", scale_units="xy", scale=3.0, width=0.006)
    circle = np.linspace(0.0, 2.0 * np.pi, 200)
    ax_left.plot(radius * np.cos(circle), radius * np.sin(circle), ":",
                 color="gray", linewidth=1.0)
```

`plt.subplots(1, 2, figsize=(10.0, 4.6))` makes one figure with two panels side by side, called `ax_left` and `ax_right`. `np.arange(12) * np.pi / 6` is the list of the twelve angles $0, \pi/6, \ldots, 11\pi/6$ (30 degrees apart). For the radii 1 and 2 the points $(r\cos\varphi, r\sin\varphi)$ are computed, and `quiver` draws an arrow at each point: the unit radial direction $(\cos\varphi, \sin\varphi)$ in black and the unit angular direction $(-\sin\varphi, \cos\varphi)$ in orange. The options `angles="xy", scale_units="xy", scale=3.0` draw an arrow of length one third in the units of the axes. The dotted circle is drawn through 200 points.

```
ax_left.plot([], [], color="black", label="unit radial direction $e_{(0)}$")
ax_left.plot([], [], color="tab:orange", label="unit angular direction $e_{(1)}$")
ax_left.set_aspect("equal")
ax_left.set_xlim(-2.8, 2.8)
ax_left.set_ylim(-2.8, 3.6)  # room for the legend above the circles
ax_left.set_xlabel("Cartesian $x = r\\cos\\varphi$")
ax_left.set_ylabel("Cartesian $y = r\\sin\\varphi$")
ax_left.set_title("The polar frame turns with the angle")
ax_left.legend(loc="upper left", fontsize=8)
```

Two empty plots (`[]`, `[]`) only create the legend entries. `set_aspect("equal")` makes one unit equally long on both axes, so the circles look round. The axis limits leave room for the legend above the circles; the axes are labelled and the legend is placed in the upper left corner.

```
turn = np.linspace(0.0, 4.0 * np.pi, 400)  # phi from 0 to 4 pi
ax_right.plot(turn / np.pi, np.cos(turn / 2), label="$\\cos(\\varphi/2)$, real part")
ax_right.plot(turn / np.pi, np.sin(turn / 2), "--",
              label="$\\sin(\\varphi/2)$, imaginary part")
ax_right.set_xlabel("$\\varphi / \\pi$")
ax_right.set_ylabel("entry $U_{11}$ of the spinor rotation")
ax_right.set_ylim(-1.45, 1.2)  # room for the legend below the curves
ax_right.set_title("A spinor turns by half the angle")
ax_right.legend(loc="lower center", ncol=2, fontsize=8)
```

The right panel draws the entry $U_{11} = \cos\frac{\varphi}{2} + i\sin\frac{\varphi}{2}$ of the spinor rotation U (the rotation that carries the Cartesian frame into the polar frame; its inverse U^{-1} removes the connection, Section 6.5) for 400 values of φ from 0 to 4π: its real part $\cos(\varphi/2)$ as a solid line and its imaginary part $\sin(\varphi/2)$ dashed (the style string of two minus signs). The horizontal axis shows φ/π, so the full turn is at 2 and the double turn at 4. In the labels `\\` is a single backslash for matplotlib's formula typesetting.

```
save_figure(fig, "polar_frame_and_spin_rotation",
            "Warm-up in the flat plane. Left: the unit radial direction (black) and "
            ...
            "rotation is $-1$, and only at $4\\pi$ is it $+1$ again.")
```

`save_figure` saves the figure with its caption, shows it and prints one line with the name of the saved file, `06a_1_polar_frame_and_spin_rotation.png` in the folder `Revision/textbook/figures`.

What Figure 06a.1 shows. On the left, the black and orange arrows turn together as one goes around the circle: the polar frame at the angle φ is the Cartesian frame turned by φ. That turning is exactly what $\omega_{\varphi 01} = -1$ records, although the plane is flat; the spinor rotation $U(\varphi)$ performs the same turning on spinors, and its inverse U^{-1} turns it back and removes the connection. On the right, the solid curve $\cos(\varphi/2)$ reaches -1 at $\varphi = 2\pi$ (the value 2 on the axis), where the dashed curve is 0: after one full turn the spinor rotation is -1, and only at 4π is it $+1$ again. A spinor turns by half the angle of its frame.

In [7], the author's metric and its vielbein (Section 6.2).

```
x = sp.symbols("x0:8", real=True)  # x[0] = x0, ..., x[4] = x4, ..., x[7] = x7
x0, x4 = x[0], x[4]  # the hidden direction and the time
H = sp.Symbol("H", positive=True)  # the author's constant H > 0
a4 = sp.Function("a4")(x4)  # the metric function a4(x4): any function of the time
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4(x4) > 0
z = 6 * H * x0  # the hidden angle z = 6 H x0, between 0 and pi/2
s = sp.sin(z) ** sp.Rational(1, 6)  # sin^(1/6) z
f = ([sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
     + [sp.exp(-a4) * sp.sqrt(b4) * s] * 3)  # f_0, ..., f_7
g = sp.diag(*[ETA[a] * f[a] ** 2 for a in range(8)])  # g_aa = eta_aa f_a^2
e = sp.diag(*f)  # the diagonal vielbein e^a_mu = f_a delta^a_mu
```

`sp.symbols("x0:8", real=True)` makes the eight real symbols $x_0, \ldots, x_7$ (the range `0:8` stops before 8); `x[0]` is x_0 and `x[4]` is x_4. `H` is positive. `sp.Function("a4")(x4)` is an unknown function of x_4, and `sp.Function("b4", positive=True)(x4)` an unknown positive function of x_4: every result below holds for all functions a_4 and $b_4 > 0$. `z` is $6Hx_0$, `s` is $\sin^{1/6} z$ (`sp.Rational(1, 6)` is the exact fraction $\frac{1}{6}$). The list `f` holds the eight factors in the order $x0, \ldots, x7$: `[...] * 3` repeats a one-element list three times, `+` joins lists, and `sp.sqrt(b4)` is $b_4^{1/2}$. `g` is the diagonal matrix with the entries $\eta_{aa} f_a^2$ (`sp.diag(*list)` puts the list on the diagonal), and `e` the diagonal vielbein.

```
# The names under which the records write symbols, and our symbols for them:
RECORD_NAMES = {"H": H, "x4": x4, "x0": x0, "a4": a4, "b4": b4,
                "a4p": sp.Derivative(a4, x4), "a4pp": sp.Derivative(a4, (x4, 2)),
                "b4p": sp.Derivative(b4, x4), "b4pp": sp.Derivative(b4, (x4, 2))}
AT_B4_1 = {b4: 1}  # the background b4 = 1

def at_b4_1(expr):
    return sp.sympify(expr).subs(AT_B4_1).doit()

metric_b4 = json.loads(repository_file(METRIC_B4_FILE).read_text(encoding="utf-8"))
diagonal_b4 = [wolfram_to_sympy(text, RECORD_NAMES)
               for text in metric_b4["metricDiagonal"]]
check(all(is_zero(g[a, a] - diagonal_b4[a]) for a in range(8))
      and record_passed(REPORT_WL_B4, "metric_is_the_authors_b4"),
      "eta_aa f_a^2 is the author's metric with b4 (all eight diagonal entries)",
      record=f"{METRIC_B4_FILE}, key metricDiagonal")
```

```
metric_record = sp.Matrix([list(row) for row in record_formula("metric", RECORD_NAMES)])
f_record = record_formula("vielbein_diagonal", RECORD_NAMES)
```

The records write their symbols as plain names; `RECORD_NAMES` says which symbol or function of the notebook each name means (`sp.Derivative(a4, x4)` is a_4', `sp.Derivative(a4, (x4, 2))` is a_4'', and the same for b_4). `at_b4_1(expr)` puts $b_4 = 1$ into an expression; sympy leaves a derivative of the constant 1 written as `Derivative(1, x4)`, and `.doit()` evaluates it to 0. The record `metric-b4.json` lists the eight diagonal entries of the metric with b_4 under the key `metricDiagonal`; they are read and compared with g, and the WolframScript report with b_4 must record `metric_is_the_authors_b4` as passed. The metric of the record of $b_4 = 1$ is read as a nested list and turned into a matrix (`list(row)` makes each row a list), and that record's eight vielbein factors are read as a list.

```
check(matrix_is_zero(at_b4_1(g) - metric_record)
      and all(is_zero(at_b4_1(f[a]) - f_record[a]) for a in range(8))
      and record_passed(REPORT_LEAD, "vielbein_reproduces_metric"),
      "at b4 = 1: the metric and the eight vielbein factors of the record",
      record=f"{THEORY_FILE}, formulas metric and vielbein_diagonal")
```

The second check requires, at $b_4 = 1$, all 64 entries of g minus the record's metric to vanish, the eight factors to equal the record's, and the lead's independent report to record `vielbein_reproduces_metric` as passed.

```
volume = sp.simplify(sp.prod(f))  # f_0 f_1 ... f_7
say(f"f_0 f_1 ... f_7 = {volume}")
volume_record = wolfram_to_sympy(metric_b4["sqrtAbsDetG"], RECORD_NAMES)
check(is_zero(volume - b4 ** sp.Rational(3, 2) * sp.cos(z))
      and is_zero(volume - volume_record) and is_zero(volume**2 - g.det())
      and record_passed(REPORT_WL_B4, "sqrt_det_g"),
      "sqrt|det g| = f_0 f_1 ... f_7 = b4^(3/2) cos z (cos z at b4 = 1)",
      record=f"{METRIC_B4_FILE}, key sqrtAbsDetG")
```

`sp.prod(f)` multiplies the eight factors, and the simplified product is printed: `f_0 f_1 ... f_7 = b4(x4)**(3/2)*cos(6*H*x0)`. The check requires it to be $b_4^{3/2}\cos z$, to equal the record's `sqrtAbsDetG`, and its square to be the determinant of g (`g.det()`), so that it is $\sqrt{|\det g|}$. The cell prints three PASS lines with their records and the product.

In [8], figure 2.

```
X4_SYMBOL = sp.Symbol("t", real=True)  # the time x4 as a plain symbol for numbers
history = {a4: X4_SYMBOL, b4: 1}  # illustrative: a4(x4) = x4, b4 = 1 (with H = 1)
f_of_time = sp.lambdify(X4_SYMBOL, [fa.subs(history).subs({H: 1, x0: sp.pi / 24})
                                    for fa in f])  # z = 6 x0 = pi/4
times = np.linspace(-2.0, 2.0, 201)
values = [np.broadcast_to(v, times.shape) for v in f_of_time(times)]
```

For numbers the unknown functions must be given a form. `history` replaces $a_4(x_4)$ by the plain symbol `t` and b_4 by 1: the illustrative history $a_4 = x_4$, $b_4 = 1$ (with $H = 1$, the prescribed background of Chapter 3 with slope 1). `sp.lambdify(t, [...])` turns the eight factors, with

$H = 1$ and $x_0 = \pi/24$ (so $z = 6x_0 = \pi/4$), into one numerical function of `t` that returns the eight values. `times` is a list of 201 times from -2 to 2. The factor $f_4 = 1$ does not depend on `t`, so `lambdify` returns the single number 1 for it; `np.broadcast_to(v, times.shape)` turns such a number into a list of 201 equal values, so that every curve can be plotted.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.4))
ax_left.semilogy(times, values[1], label="$f_1 = f_2 = f_3 = e^{a_4}s$ (3-space)")
ax_left.semilogy(times, values[5], "--",
                 label="$f_5 = f_6 = f_7 = e^{-a_4}b_4^{1/2}s$ (extra times)")
ax_left.semilogy(times, values[4], ":", color="black", label="$f_4 = 1$ (time)")
ax_left.semilogy(times, values[1] * values[5], "-.", color="gray",
                 label="product $f_1 f_5 = b_4^{1/2}s^2$")
ax_left.set_xlabel("time $x_4$ (units $1/H$), history $a_4 = x_4$, $b_4 = 1$")
ax_left.set_ylabel("vielbein factor (logarithmic axis)")
ax_left.set_title("Inflating 3-space, deflating extra times")
ax_left.legend(fontsize=8)
```

`semilogy` plots with a logarithmic vertical axis, on which an exponential function is a straight line. Four curves (positions 1, 5 and 4 of the list): $f_1 = e^{a_4}s$ (solid), $f_5 = e^{-a_4}b_4^{1/2}s$ (dashed), $f_4 = 1$ (dotted, black) and the product $f_1 f_5 = b_4^{1/2}s^2$ (dash-dotted, gray).

```
zz = np.linspace(0.02, np.pi / 2 - 0.02, 300)  # z inside (0, pi/2)
ax_right.plot(zz, np.sin(zz) ** (1 / 6), label="$s = \\sin^{1/6} z$")
ax_right.plot(zz, 1 / np.tan(zz), "--", label="$f_0 = \\cot z$ (hidden)")
ax_right.plot(zz, np.cos(zz), ":", color="black",
              label="$\\sqrt{|\\det g|} = \\cos z$ ($b_4 = 1$)")
ax_right.set_ylim(0.0, 3.0)
ax_right.set_xlabel("hidden angle $z = 6 H x_0$ (radians)")
ax_right.set_ylabel("factor (pure number)")
ax_right.set_title("Dependence on the hidden direction")
ax_right.legend(fontsize=8)
```

The right panel uses 300 values of z inside $(0, \pi/2)$ (0.02 away from both ends, where $\cot z$ would be infinite) and draws $s = \sin^{1/6} z$, $f_0 = \cot z$ $(1/\tan z)$ and the volume factor $\cos z$ of $b_4 = 1$. `set_ylim(0.0, 3.0)` cuts the axis at 3, because $\cot z$ grows without bound near $z = 0$.

```
save_figure(fig, "vielbein_factors",
            "The eight factors $f_a$ of the diagonal vielbein. Left: versus the time "
            ...
            "$a_4 = x_4$, $b_4 = 1$, on a logarithmic axis; the 3-space factor "
            "$e^{a_4}s$ grows and the extra-time factor $e^{-a_4}b_4^{1/2}s$ shrinks "
            "at the same exponential rate, so their product $b_4^{1/2}s^2$ stays "
            "constant, and the time factor is $1$. Right: versus the hidden angle "
            "$z = 6Hx_0$ in radians at $x_4 = 0$; $s = \\sin^{1/6}z$, the hidden "
            "factor $\\cot z$, which falls from very large values to $0$, and the "
            "volume factor $\\sqrt{|\\det g|} = b_4^{3/2}\\cos z$ at $b_4 = 1$, which "
            "depends on the time only through $b_4$.")
```

The figure is saved with its caption; the cell prints the name of the saved file, `06a_2_vielbein_factors.png`.

What Figure 06a.2 shows. On the left, the 3-space factor rises and the extra-time factor falls along straight lines of opposite slope (on a logarithmic axis an exponential is a straight line): 3-space inflates while the extra times deflate exponentially, at the same rate. Their product is the flat gray line s^2 (here $b_4 = 1$), and the time factor is 1. On the right, as functions of the hidden angle: s rises slowly to 1, the hidden factor $\cot z$ falls from very large values near the tip $z = 0$ to 0 at the patch end $z = \pi/2$, and the volume factor $\cos z$ falls from 1 to 0. For $b_4 = 1$ the volume factor does not depend on the time at all, and in general only through $b_4^{3/2}$; Section 6.9 showed why this matters.

In [9], the Christoffel symbols (Section 6.3).

```
Gam = christoffel(g, x)
independent = {(l, m, n): Gam[l][m][n] for l in range(8) for m in range(8)
               for n in range(m, 8) if Gam[l][m][n] != 0}
report("number of independent nonzero Christoffel symbols", len(independent))
```

`christoffel(g, x)` computes all $8 \cdot 8 \cdot 8 = 512$ symbols. The dictionary `independent` keeps those with $m \le n$ (`range(m, 8)`) that are not zero, under the key `(l, m, n)`. `report` prints their number, 25.

```
def as_dictionary(entries):
    return {(int(l) - 1, int(m) - 1, int(n) - 1): value for l, m, n, value in entries}

record_b4 = as_dictionary(record_formula("christoffel_nonzero", RECORD_NAMES,
                                         FORMULAS_B4))
record_b4_1 = as_dictionary(record_formula("christoffel_nonzero", RECORD_NAMES))
same_b4 = set(record_b4) == set(independent) and all(
    is_zero(independent[key] - record_b4[key]) for key in independent)
same_b4_1 = set(record_b4_1) == set(independent) and all(
    is_zero(at_b4_1(independent[key]) - record_b4_1[key]) for key in independent)
```

The records' lists `christoffel_nonzero` have entries $\{l, m, n, \text{value}\}$ with the directions numbered from 1 in the order $x0, \ldots, x7$ (the number 1 is $x0$); `as_dictionary` subtracts 1 to get Python's positions. The list of the record with b_4 is compared with the symbols as they are, the list of the record of $b_4 = 1$ with the symbols at $b_4 = 1$. `set(record_b4) == set(independent)` requires the same 25 keys on both sides (a **set** is a collection without order), and `all(...)` requires every value to agree exactly.

```
for key in [(1, 1, 4), (5, 4, 5), (1, 0, 1), (4, 5, 5), (0, 0, 0)]:
    l, m, n = key
    say(f"Gamma^{NAMES[l]}_{NAMES[m]}{NAMES[n]} = {independent[key]}")
```

Five symbols are printed as examples: ${\Gamma^{x1}}_{x1x4} = a_4'$, ${\Gamma^{x5}}_{x4x5} = -a_4' + b_4'/(2b_4)$, ${\Gamma^{x1}}_{x0x1} = H/\tan z$, ${\Gamma^{x4}}_{x5x5} = e^{-2a_4} b_4 \sin^{1/3} z\,(a_4' - b_4'/(2b_4))$ (sympy prints it as `(b4(x4)*Derivative(a4(x4), x4) - Derivative(b4(x4), x4)/2)*exp(-2*a4(x4))*sin(6*H*x0)**(1/3)`) and ${\Gamma^{x0}}_{x0x0} = -12H/\sin 12Hx_0 = -12H/\sin 2z$, as derived in Section 6.3 (sympy prints the power $\frac{1}{3}$ as `**(1/3)` and a_4' as `Derivative(a4(x4), x4)`).

```
check(len(independent) == 25 and same_b4 and same_b4_1,
      "the 25 independent nonzero Christoffel symbols equal the records (with b4, and "
      "at b4 = 1)",
      record=f"{THEORY_B4_FILE} and {THEORY_FILE}, formula christoffel_nonzero")
```

The check requires 25 symbols equal to the records' (with b_4, and at $b_4 = 1$); it prints PASS and the records.

In [10], figure 3.

```
SAMPLE = {H: 1, x0: sp.pi / 24}  # H = 1 and z = 6 H x0 = pi/4

def at_sample(expr):
    """The decimal value of expr at the sample point H = 1, z = pi/4, a4 = 1/2,
    a4' = 1/2, b4 = 1, b4' = 1/2, a4'' = b4'' = 0 (derivatives are replaced first,
    then the functions themselves)."""
    expr = sp.sympify(expr)
    for function, first in ((a4, sp.Rational(1, 2)), (b4, sp.Rational(1, 2))):
        expr = expr.subs(sp.Derivative(function, (x4, 2)), 0)
        expr = expr.subs(sp.Derivative(function, x4), first)
    expr = expr.subs({a4: sp.Rational(1, 2), b4: 1})
    return complex(sp.N(expr.subs(SAMPLE)))
```

`SAMPLE` fixes $H = 1$ and $x_0 = \pi/24$, so $z = \pi/4$. `at_sample(expr)` gives the decimal value of an expression at the **sample point** $H = 1$, $z = \pi/4$, $a_4 = \frac{1}{2}$, $a_4' = \frac{1}{2}$, $b_4 = 1$, $b_4' = \frac{1}{2}$, $a_4'' = b_4'' = 0$. The order of the replacements matters: for each function the derivatives are replaced first, because replacing $a_4(x_4)$ by the number $\frac{1}{2}$ first would turn a_4' into the derivative of a constant, which is 0. `sp.N` evaluates the expression as a decimal number, and `complex(...)` makes it an ordinary Python number.

```
fig, axes = plt.subplots(2, 4, figsize=(10.0, 5.6))
for l, ax in enumerate(axes.flat):
    signs = np.array([[np.sign(at_sample(Gam[l][m][n]).real) for n in range(8)]
                      for m in range(8)])
    ax.imshow(signs, cmap="RdBu_r", vmin=-1.5, vmax=1.5)
    ax.set_title(f"$\\Gamma^{{{x{l}}}{{}}_{{mn}}$", fontsize=9)
    ax.set_xticks(range(8), [f"{k}" for k in range(8)], fontsize=7)
    ax.set_yticks(range(8), [f"{k}" for k in range(8)], fontsize=7)
    ax.set_xlabel("$n$ (x-number)", fontsize=7)
    ax.set_ylabel("$m$ (x-number)", fontsize=7)
    ax.grid(False)
fig.suptitle("Signs of the Christoffel symbols at a sample point "
             "(red +, blue -, white 0)", fontsize=10)
fig.tight_layout()
```

`plt.subplots(2, 4)` makes eight small panels in two rows, one for each upper index `l`; `enumerate(axes.flat)` numbers them 0 to 7. For each panel an 8×8 table of the signs $+1$, -1 or 0 of ${\Gamma^l}_{mn}$ at the sample point is computed (`np.sign`; `.real` takes the real part of the complex number) and drawn by `imshow` as a picture whose squares are coloured with the colour map `"RdBu_r"` (red for

positive, blue for negative, white for zero). The tick labels number the rows and columns 0 to 7, the numbers of the directions $x0$ to $x7$; `ax.grid(False)` removes the grid lines; `fig.suptitle` puts a title above all panels and `fig.tight_layout()` arranges them without overlap. In the title string the doubled braces `{{` and `}}` print single braces inside an f-string.

```
save_figure(fig, "christoffel_pattern",
            "Where the Christoffel symbols $\\Gamma^l{}_{mn}$ of the author's metric "
            ...
            "\\pi/4$, $a_4 = 1/2$, $a_4' = 1/2$, $b_4 = 1$, $b_4' = 1/2$ (red "
            "positive, blue negative, white zero). Every nonzero symbol has an index "
            "equal to 0 or 4: the metric depends only on the hidden coordinate $x_0$ "
            "and on the time $x_4$. The grids are symmetric because "
            "$\\Gamma^l{}_{mn} = \\Gamma^l{}_{nm}$.")
```

The figure is saved; the cell prints the name of the saved file, `06a_3_christoffel_pattern.png`.

What Figure 06a.3 shows. Every coloured square lies in row 0 or 4, in column 0 or 4, or in a panel $l = x0$ or $l = x4$: every nonzero symbol carries an index $x0$ or $x4$, because the metric depends only on the hidden coordinate and on the time. Each grid is mirror-symmetric about its diagonal, because $\Gamma^l{}_{mn} = \Gamma^l{}_{nm}$. In the panels $l = x1, x2, x3$ the two squares with the index 4 are red ($a_4' > 0$: 3-space grows), and in the panels $l = x5, x6, x7$ they are blue ($\alpha_t = -a_4' + b_4'/(2b_4) = -\frac{1}{4}$ at the sample point: the extra times shrink). The panel $l = x4$ has red squares on the diagonal for all six warped directions, and the panel $l = x0$ has blue squares for 3-space, red squares for the extra times and one blue square at $(0, 0)$, as the signs derived in Section 6.3 say.

In [11], the canonical spin connection (Sections 6.4 and 6.6).

```
omega = spin_connection(e, Gam, x, ETA)
postulate = [sp.diff(e[a, nu], x[mu])
             - sum(Gam[lam][mu][nu] * e[a, lam] for lam in range(8))
             + sum(ETA[a] * omega[mu][a][b] * e[b, nu] for b in range(8))
             for mu in range(8) for a in range(8) for nu in range(8)]
check(len(postulate) == 512 and all(is_zero(v) for v in postulate),
      "the vielbein postulate holds in all 512 components",
      record=f"{REPORT_PY}, check vielbein_postulate")
```

`omega` holds all $8^3 = 512$ components $\omega_{\mu ab}$. The list `postulate` holds the left side of the vielbein postulate for every μ, a, ν; the mixed components are recovered as $\omega_\mu{}^a{}_b = \eta_{aa}\omega_{\mu ab}$ (multiplying by η_{aa} again undoes the lowering, because $\eta_{aa}^2 = 1$). The check requires 512 entries, all exactly zero.

```
check(all(is_zero(omega[mu][a][b] + omega[mu][b][a])
          for mu in range(8) for a in range(8) for b in range(8)),
      "omega_mu ab = -omega_mu ba for all mu, a, b",
      record=f"{REPORT_PY}, check spin_connection_antisymmetric")
```

The antisymmetry $\omega_{\mu ab} + \omega_{\mu ba} = 0$, checked for all 512 triples.

```
omega_nonzero = {(mu, a, b): omega[mu][a][b] for mu in range(8) for a in range(8)
                 for b in range(a + 1, 8) if omega[mu][a][b] != 0}
for (mu, a, b), value in omega_nonzero.items():
    say(f"omega_{NAMES[mu]},{NAMES[a]}{NAMES[b]} = {value}")
```

The nonzero components with $a < b$ are collected and printed, one line each (a long line continues, indented, on the next): twelve lines such as

```
omega_x1,x1x4 = exp(a4(x4))*sin(6*H*x0)**(1/6)*Derivative(a4(x4), x4)
```

which is $a_4' e^{a_4} s$, and

```
omega_x5,x4x5 = (-b4(x4)*Derivative(a4(x4), x4) + Derivative(b4(x4),
    x4)/2)*exp(-a4(x4))*sin(6*H*x0)**(1/6)/sqrt(b4(x4))
```

which is $-(a_4' - b_4'/(2b_4))e^{-a_4} b_4^{1/2} s$: exactly the table of Section 6.6.

```
omega_record = as_dictionary(record_formula("omega_nonzero", RECORD_NAMES,
                                            FORMULAS_B4))
omega_record_1 = as_dictionary(record_formula("omega_nonzero", RECORD_NAMES))
check(len(omega_nonzero) == 12 and set(omega_record) == set(omega_nonzero)
      and all(is_zero(omega_nonzero[k] - omega_record[k]) for k in omega_nonzero)
      and set(omega_record_1) == set(omega_nonzero)
      and all(is_zero(at_b4_1(omega_nonzero[k]) - omega_record_1[k])
              for k in omega_nonzero),
      "the 12 independent nonzero omega_mu ab equal the records (with b4, and at "
      "b4 = 1)",
      record=f"{THEORY_B4_FILE} and {THEORY_FILE}, formula omega_nonzero")
```

The records' lists `omega_nonzero` (entries $\{\mu, a, b, \text{value}\}$) are read and renumbered; the check requires exactly 12 components, the same keys and the same values as the record with b_4, and at $b_4 = 1$ as the record of $b_4 = 1$.

```
a4p, b4p = sp.Derivative(a4, x4), sp.Derivative(b4, x4)
rates = (a4p, a4p - b4p / (2 * b4), H)  # 3-space, the extra times, hidden direction
factors = [sign * phys for sign in (1, -1)
           for phys in (sp.exp(a4) * s, sp.exp(-a4) * sp.sqrt(b4) * s)]
# value / (rate * factor) must simplify to exactly 1 for one choice of each.
shape_ok = all(any(sp.simplify(value / (rate * phys)) == 1 for rate in rates
                   for phys in factors) for value in omega_nonzero.values())
check(shape_ok and record_passed(REPORT_WL_B4, "omega_components"),
      "every nonzero omega is a4', a4' - b4'/(2 b4) or H times +-exp(a4) s or "
      "+-exp(-a4) b4^(1/2) s",
      record=f"{REPORT_WL_B4}, check omega_components")
```

The last check makes the statement of Section 6.6 precise: for every nonzero component there is a choice of `rate` (one of a_4', $a_4' - b_4'/(2b_4)$ and H) and of `phys` (one of the four factors $\pm e^{a_4} s$, $\pm e^{-a_4} b_4^{1/2} s$) such that the component divided by `rate * phys` simplifies to exactly 1. `any(...)` is true when at least one choice works. The cell prints the twelve components and four PASS lines.

In [12], figure 4.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.6))
for ax, mu in zip(axes, (1, 5)):  # the directions x1 and x5
```

```
    table = np.array([[at_sample(omega[mu][a][b]).real for b in range(8)]
                      for a in range(8)])
    limit = np.abs(table).max()
    image = ax.imshow(table, cmap="RdBu_r", vmin=-limit, vmax=limit)
```

Two panels, for $\mu = x1$ (position 1) and $\mu = x5$ (position 5); `zip(axes, (1, 5))` pairs each panel with its μ. `table` is the 8×8 array of the values $\omega_{\mu ab}$ at the sample point. The colour scale is symmetric, from minus to plus the largest absolute value `limit`, so that white means zero.

```
    for a in range(8):
        for b in range(8):
            if table[a, b] != 0:
                ax.text(b, a, f"{table[a, b]:.2f}", ha="center", va="center",
                        fontsize=7)
```

Each nonzero value is written into its square with two decimals (`f"{...:.2f}"`), centred.

```
    ax.set_xticks(range(8), NAMES, fontsize=8)
    ax.set_yticks(range(8), NAMES, fontsize=8)
    ax.set_xlabel("frame index $b$")
    ax.set_ylabel("frame index $a$")
    ax.set_title(f"$\\omega_{{x{mu}\\,ab}}$ at the sample point")
    ax.grid(False)
    fig.colorbar(image, ax=ax, shrink=0.8)
fig.tight_layout()
```

The tick labels are the names $x0$ to $x7$, the axes are the frame indices a (rows) and b (columns), and each panel gets its own **colour bar** (`fig.colorbar`), the scale that translates colours into numbers.

```
save_figure(fig, "omega_heat_maps",
            "The canonical spin connection $\\omega_{\\mu ab}$ of the diagonal "
            ...
            "3-space direction $x1$.")
```

The figure is saved; the cell prints the name of the saved file, `06a_4_omega_heat_maps.png`.

What Figure 06a.4 shows. For $\mu = x1$ the only nonzero squares are $(x1, x4) = 0.78$ and $(x1, x0) = 1.56$ with their mirror images -0.78 and -1.56: the antisymmetry. These numbers are $a_4' e^{a_4} s$ and $H e^{a_4} s$ at the sample point, where $e^{a_4} s = e^{1/2} \sin^{1/6}(\pi/4) = 1.556$. For $\mu = x5$ the nonzero squares are $(x4, x5) = -0.14$ and $(x5, x0) = -0.57$ with their mirror images: $-(a_4' - \frac{b_4'}{2b_4}) e^{-a_4} b_4^{1/2} s$ and $-H e^{-a_4} b_4^{1/2} s$, with $e^{-a_4} b_4^{1/2} s = 0.572$ and $a_4' - b_4'/(2b_4) = \frac{1}{4}$. The extra time has the opposite signs of the 3-space direction and smaller values, because its factor e^{-a_4} is smaller than e^{a_4} when $a_4 > 0$, and the growing b_4 ($b_4' = \frac{1}{2}$) halves its time rate.

In [13], the spinor connection and the covariant constancy (Section 6.7).

```
Omega = spinor_connection(omega, S)  # eight 16 x 16 matrices
gup = curved_gammas(e, gamma)  # gamma^mu = gamma^a / f_a for mu = a
check(Omega[0] == Z16 and Omega[4] == Z16, "Omega_x0 = Omega_x4 = 0 for every b4",
      record=f"{REPORT_PY}, check Omega_x0_and_Omega_x4_vanish (b4 = 1)")
```

`Omega` is the list of the eight matrices Ω_μ and `gup` the list of the curved gammas, $\gamma^{(\mu)}/f_\mu$. The first check requires Ω_{x0} and Ω_{x4} (positions 0 and 4) to be the zero matrix, for every b_4; the record named in its second line states this at $b_4 = 1$.

```
rotation_ok = all(matrix_is_zero(
    Omega[mu] * gamma[a] - gamma[a] * Omega[mu]
    + sum((ETA[a] * omega[mu][a][b] * gamma[b] for b in range(8)), Z16))
    for mu in range(8) for a in range(8))
check(rotation_ok, "[Omega_mu, gamma^a] = -omega_mu^a_b gamma^b for all 64 pairs",
      record=f"{REPORT_WL}, check S_rotates_gamma_with_omega (b4 = 1)")
```

The defining property $[\Omega_\mu, \gamma^a] + \sum_b \omega_\mu{}^a{}_b \gamma^b = 0$, with $\omega_\mu{}^a{}_b = \eta_{aa}\omega_{\mu ab}$, checked for all 64 pairs (μ, a).

```
constancy_ok = all(matrix_is_zero(
    gup[nu].diff(x[mu]) + sum((Gam[nu][mu][lam] * gup[lam] for lam in range(8)), Z16)
    + Omega[mu] * gup[nu] - gup[nu] * Omega[mu])
    for mu in range(8) for nu in range(8))
check(constancy_ok and record_passed(REPORT_WL_B4, "gamma_covariantly_constant"),
      "D_mu gamma^nu = 0 for all 64 pairs (mu, nu)",
      record=f"{REPORT_WL_B4}, check gamma_covariantly_constant")
```

The covariant constancy $D_\mu \gamma^\nu = \partial_\mu \gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0$, checked for all 64 pairs (μ, ν) (`.diff(x[mu])` differentiates every entry of the matrix); the WolframScript report with b_4 must record the same.

```
say(f"Omega_x1 has {sum(1 for v in Omega[1] if v != 0)} nonzero entries of 256")
```

The last line counts the nonzero entries of Ω_{x1} and prints Omega_x1 has 32 nonzero entries of 256. Each generator $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$ is one half of a signed permutation matrix, with 16 nonzero entries, and the two generators of Ω_{x1} have them in different places: $16 + 16 = 32$.

In [14], figure 5.

```
pattern_ok = True
for a in range(8):
    for b in range(a + 1, 8):
        boost = ETA[a] * ETA[b] == -1  # one space-like, one time-like direction
        want = S[a][b] if boost else -S[a][b]  # S^T = S (boost) or -S (rotation)
        pattern_ok = pattern_ok and S[a][b].T == want
check(pattern_ok, "S^ab is symmetric for the 16 boosts, antisymmetric for the 12 "
      "rotations")
```

For all 28 pairs $a < b$ the loop decides whether the pair is a boost ($\eta_{aa}\eta_{bb} = -1$) and requires `S[a][b].T` (the transpose) to equal S^{ab} for a boost and $-S^{ab}$ for a rotation, as Section 6.7 proved.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.6))
for ax, mu in zip(axes, (1, 5)):  # the directions x1 and x5
    table = np.array([[at_sample(v).real for v in row] for row in Omega[mu].tolist()])
```

```
    limit = np.abs(table).max()
    image = ax.imshow(table, cmap="RdBu_r", vmin=-limit, vmax=limit)
    ax.set_xticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
    ax.set_yticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
    ax.set_xlabel("column (spinor component 1 to 16)")
    ax.set_ylabel("row (spinor component)")
    ax.set_title(f"$\\Omega_{{x{mu}}}$ at the sample point")
    ax.grid(False)
    fig.colorbar(image, ax=ax, shrink=0.8)
fig.tight_layout()
```

Two heat maps, of Ω_{x1} and Ω_{x5} at the sample point (`.tolist()` gives the rows of the matrix, and `at_sample` evaluates each entry). The ticks label every third component, 1, 4, 7, 10, 13, 16.

```
save_figure(fig, "spinor_connection_heat_maps",
            "The spinor connection $\\Omega_{x1}$ (left) and $\\Omega_{x5}$ (right) as "
            ...
            "components to the first eight and the last eight to the last eight.")
```

The figure is saved; the cell prints its PASS line and the saved file name.

What Figure 06a.5 shows. Each matrix has its colours only in the upper-left and the lower-right 8×8 blocks: a generator is a product of two gammas, an even product, and maps the first eight components to the first eight and the last eight to the last eight (the two chiral halves of Chapter 5). In each matrix one set of squares appears in mirror pairs of the same colour (a symmetric matrix, the boost part) and another in mirror pairs of opposite colours (an antisymmetric matrix, the rotation part). For Ω_{x1} the boost part carries a_4' (entries ± 0.39) and the rotation part H (entries ± 0.78); for Ω_{x5} the rotation part carries $a_4' - b_4'/(2b_4)$ and the boost part H (entries ± 0.07 and ± 0.29).

In [15], the contraction direction by direction (Section 6.8).

```
per_direction = []  # (alpha_mu, beta_mu) for mu = x0 ... x7
decomposed = True
for mu in range(8):
    M = (gup[mu] * Omega[mu]).applyfunc(sp.simplify)
    alpha = sp.simplify(-(M * gamma[4]).trace() / 16)  # coefficient of gamma^(x4)
    beta = sp.simplify((M * gamma[0]).trace() / 16)  # coefficient of gamma^(x0)
    decomposed = decomposed and matrix_is_zero(M - alpha * gamma[4] - beta * gamma[0])
    per_direction.append((alpha, beta))
    say(f"gamma^{NAMES[mu]} Omega_{NAMES[mu]} = ({alpha}) gamma^(x4) "
        f"+ ({beta}) gamma^(x0)")
rate_t = -a4p / 2 + b4p / (4 * b4)  # alpha of an extra time
predicted = ([(0, 0)] + [(a4p / 2, H / 2)] * 3 + [(0, 0)]
             + [(rate_t, H / 2)] * 3)  # x0, x1..x3, x4, x5..x7
check(decomposed and all(is_zero(per_direction[k][0] - predicted[k][0])
                         and is_zero(per_direction[k][1] - predicted[k][1])
                         for k in range(8))
      and record_passed(REPORT_PY_B4, "gammaOmega_per_direction")
      and record_passed(REPORT_WL_B4, "gammaOmega_per_direction"),
      "the eight terms gamma^mu Omega_mu (no sum) with b4",
      record=f"{REPORT_WL_B4}, check gammaOmega_per_direction")
```

For each μ, `M` is the matrix $\gamma^{\mu}\Omega_{\mu}$ (no sum), simplified entry by entry (`applyfunc`). Its coefficients are read off with traces as in Section 6.8 (`.trace()` is the trace; `gamma[4]` is $\gamma^{(x4)}$ and `gamma[0]` is $\gamma^{(x0)}$), and `decomposed` stays true only if $M - \alpha\gamma^{(x4)} - \beta\gamma^{(x0)}$ is the zero matrix for every μ. Each pair $(\alpha_{\mu}, \beta_{\mu})$ is stored and printed: eight lines, the table of Section 6.8.

```
table_record = record_formula("gammaOmega_per_direction", RECORD_NAMES)
check(all(is_zero(at_b4_1(per_direction[k][0]) - table_record[k][1])
          and is_zero(per_direction[k][1] - table_record[k][2]) for k in range(8)),
      "at b4 = 1 the eight terms equal the record",
      record=f"{THEORY_FILE}, formula gammaOmega_per_direction")
```

`rate_t` is the coefficient $-\frac{1}{2}a_4' + \frac{b_4'}{4b_4}$ of an extra time, and `predicted` the table of Section 6.8 in the order $x0, \ldots, x7$. The first check compares the eight computed rows with it and requires both reports with b_4 to record `gammaOmega_per_direction` as passed. The record of $b_4 = 1$ lists the table `gammaOmega_per_direction` as $\{\mu, \alpha_{\mu}, \beta_{\mu}\}$; the second check compares all eight rows at $b_4 = 1$ with it (`table_record[k][1]` is the record's α, `[k][2]` its β).

```
inflating = sp.simplify(sum(per_direction[k][0] for k in (1, 2, 3)))
deflating = sp.simplify(sum(per_direction[k][0] for k in (5, 6, 7)))
hidden = sp.simplify(sum(beta for _, beta in per_direction))
report("x4 part from the inflating x1, x2, x3", inflating)
report("x4 part from the deflating x5, x6, x7", deflating)
report("x0 part from all directions", hidden)
check(is_zero(inflating + deflating - sp.Rational(3, 4) * b4p / b4)
      and is_zero(hidden - 3 * H),
      "the a4' parts of the x4 terms cancel, (3/4) b4'/b4 remains; the x0 terms "
      "add to 3H",
      record=f"{REPORT_WL}, check gammaOmega_x4_terms_cancel (b4 = 1)")
```

The time parts of the three inflating directions (positions 1, 2, 3) and of the three deflating directions (positions 5, 6, 7) are added separately, and all eight hidden parts together. Three RESULT lines print $\frac{3}{2}a_4'$, $-\frac{3}{2}a_4' + \frac{3}{4}b_4'/b_4$ and $3H$, and the check requires the a_4' parts of the first two to cancel, leaving $\frac{3}{4}b_4'/b_4$, and the third to be $3H$.

```
slash = sum((gup[mu] * Omega[mu] for mu in range(8)), Z16)
gravity_term = 3 * H * gamma[0] + sp.Rational(3, 4) * b4p / b4 * gamma[4]
total_record = wolfram_to_sympy(
    FORMULAS_B4["gammaOmega_total"].replace('gamma["x0"]', "G0")
    .replace('gamma["x4"]', "G4"), RECORD_NAMES)
G0, G4 = sp.Symbol("G0"), sp.Symbol("G4")  # the record's gamma["x0"], gamma["x4"]
record_matrix = (total_record.coeff(G0) * gamma[0]
                 + total_record.coeff(G4) * gamma[4])
check(matrix_is_zero(slash - gravity_term) and matrix_is_zero(slash - record_matrix)
      and record_passed(REPORT_WL_B4, "gammaOmega_total"),
      "gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4) exactly",
      record=f"{THEORY_B4_FILE}, formula gammaOmega_total")
check(matrix_is_zero(at_b4_1(slash) - 3 * H * gamma[0])
      and record_passed(REPORT_LEAD, "gamma_Omega_equals_3H_gamma0"),
      "at b4 = 1 (and for every constant b4): gamma^mu Omega_mu = 3 H gamma^(x0)",
      record=f"{REPORT_LEAD}, check gamma_Omega_equals_3H_gamma0")
```

`slash` is the full sum $\sum_\mu \gamma^\mu \Omega_\mu$ and `gravity_term` the matrix $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$. The record with b_4 writes the total as text with `gamma["x0"]` and `gamma["x4"]`; these are replaced by the plain symbols `G0` and `G4` before reading, and `.coeff(G0)` and `.coeff(G4)` pick out their factors, from which `record_matrix` is built. The next check requires `slash` to equal both, for symbolic H, a_4 and b_4, and the WolframScript report with b_4 to record `gammaOmega_total` as passed. The last check puts $b_4 = 1$: then the sum is exactly $3H\gamma^{(x0)}$, and the lead's independent report must record the same. The cell prints eight lines, five PASS lines and three RESULT lines.

In [16], figure 6.

```
a4_part = [float(sp.simplify(at_b4_1(alpha) / a4p)) for alpha, _ in per_direction]
b4_part = [float(sp.simplify(alpha.subs(a4p, 0) / (b4p / b4)))
           for alpha, _ in per_direction]  # the part with b4'/b4
beta_units = [float(sp.simplify(beta / H)) for _, beta in per_direction]  # beta / H
positions = np.arange(8)
```

The coefficient of $\gamma^{(x4)}$ is split into its part with a_4' (at $b_4 = 1$, divided by a_4') and its part with b_4'/b_4 (with $a_4' = 0$, divided by b_4'/b_4); the coefficient of $\gamma^{(x0)}$ is divided by H. All are ordinary decimal numbers (`float`): $\pm\frac{1}{2}$, $\frac{1}{4}$ or 0. `positions` is the list 0 to 7, the places of the bars.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.2), sharey=True)
colors = ["gray"] + ["tab:red"] * 3 + ["gray"] + ["tab:blue"] * 3
panels = [(a4_part, "$\\gamma^{(x4)}$, part / $a_4'$"),
          (b4_part, "$\\gamma^{(x4)}$, part / $(b_4'/b_4)$"),
          (beta_units, "$\\gamma^{(x0)}$ / $H$")]
for ax, (heights, title) in zip(axes, panels):
    ax.bar(positions, heights, color=colors, width=0.6)
    ax.set_title(f"{title}: total {sum(heights):g}", fontsize=10)
```

Three bar charts with a common vertical axis (`sharey=True`), one for each of the three lists in `panels`; the bars of 3-space are red, of the extra times blue, of the hidden direction and the time gray. Each title shows the total (`:g` writes a number in its shortest form).

```
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xticks(positions, NAMES)
    ax.set_xlabel("direction $\\mu$")
axes[0].set_ylabel("coefficient (in the unit named in the title)")
```

A black zero line, the direction names under the bars, and the axis labels.

```
save_figure(fig, "gamma_omega_per_direction",
            "The eight terms $\\gamma^\\mu\\Omega_\\mu$ (no sum) of the diagonal "
            ...
            "\\beta_\\mu\\gamma^{(x0)}$; horizontal axis the direction $\\mu$ (red: "
            "inflating 3-space, blue: deflating extra times, gray: hidden direction "
            "and time). Left: the part of $\\alpha_\\mu$ proportional to $a_4'$, in "
            "units of $a_4'$: $+1/2$ for $x1, x2, x3$ and $-1/2$ for $x5, x6, x7$, "
            "total $0$. Middle: the part proportional to $b_4'/b_4$, in units of "
            "$b_4'/b_4$: $1/4$ for each extra time, total $3/4$. Right: $\\beta_\\mu$ "
            "in units of $H$: six times $1/2$, total $3$. So $\\gamma^\\mu\\Omega_\\mu "
            "= 3H\\gamma^{(x0)} + \\frac34(b_4'/b_4)\\gamma^{(x4)}$.")
```

The figure is saved; the cell prints its file name.

What Figure 06a.6 shows. On the left, three red bars of height $+\frac{1}{2}$ and three blue bars of height $-\frac{1}{2}$: the a'_4 parts of the time-direction terms of the inflating and the deflating directions cancel, total 0. In the middle, three blue bars of height $\frac{1}{4}$: the b'_4/b_4 parts come from the extra times alone, total $\frac{3}{4}$. On the right, six bars of height $\frac{1}{2}$ all pointing up: the hidden-direction terms add, total 3. The gray directions $x0$ and $x4$ contribute nothing, because $\Omega_{x0} = \Omega_{x4} = 0$.

In [17], the block form and figure 7.

```
I8, Z8 = sp.eye(8), sp.zeros(8, 8)  # 8 x 8 identity and zero matrices
blocks_ok = True
for entry in FORMULAS["field_equation_blocks"]:  # eight texts {"xa", tb, t}
    name, tb, t = json.loads(entry.replace("{", "[").replace("}", "]"))
    a = NAMES.index(name)  # the position of the direction xa (0 ... 7)
    # gamma^(xa) must be the block matrix with the zero blocks on the diagonal
    blocks_ok = blocks_ok and gamma[a] == sp.BlockMatrix(
        [[Z8, sp.Matrix(tb)], [sp.Matrix(t), Z8]]).as_explicit()
check(blocks_ok and len(FORMULAS["field_equation_blocks"]) == 8,
      "the eight gammas have the block form of the record",
      record=f"{THEORY_FILE}, formula field_equation_blocks")
check(gamma[0] == sp.BlockMatrix([[Z8, I8], [I8, Z8]]).as_explicit(),
      "gamma^(x0) has the 8 x 8 identity in its two off-diagonal blocks")
```

The record's formula `field_equation_blocks` is a list of eight texts {"xa", $\bar\tau, \tau$} written with curly brackets. Replacing the curly brackets by square brackets turns each text into JSON, which `json.loads` reads into a name and two 8×8 lists. `NAMES.index(name)` finds the position of the direction. `sp.BlockMatrix([[Z8, tb], [t, Z8]]).as_explicit()` builds the 16×16 matrix with zero blocks on the diagonal and the two blocks off it; the first check requires all eight gammas to have this form. The second requires $\gamma^{(x0)}$ to have the 8×8 identity in both off-diagonal blocks.

```
panels = [
    ("sum over $x1, x2, x3$", sum((gup[k] * Omega[k] for k in (1, 2, 3)), Z16)),
    ("sum over $x5, x6, x7$", sum((gup[k] * Omega[k] for k in (5, 6, 7)), Z16)),
    ("total $\\gamma^\\mu\\Omega_\\mu$", slash),
    ("$3H\\gamma^{(x0)} + \\frac{3}{4}\\frac{b_4'}{b_4}\\gamma^{(x4)}$", gravity_term),
]
```

The four matrices of the figure: the sum of the three inflating terms (positions 1, 2, 3), the sum of the three deflating terms (positions 5, 6, 7), the total and $3H\gamma^{(x0)} + \frac{3}{4}(b'_4/b_4)\gamma^{(x4)}$, each with its title.

```
fig, axes = plt.subplots(2, 2, figsize=(8.0, 7.6))
for ax, (title, matrix) in zip(axes.flat, panels):
    table = np.array([[at_sample(v).real for v in row] for row in matrix.tolist()])
    image = ax.imshow(table, cmap="RdBu_r", vmin=-3.5, vmax=3.5)
    ax.set_title(title, fontsize=10)
    ax.set_xticks([])
    ax.set_yticks([])
    ax.grid(False)
fig.colorbar(image, ax=axes, shrink=0.7, label="entry value")
```

A 2×2 grid of heat maps, all on the same colour scale from -3.5 to 3.5, without tick marks, and one common colour bar.

```
save_figure(fig, "gamma_omega_cancellation",
            "The sum as pictures of 16 x 16 matrices at the sample point "
            "$H = 1$, $z = \\pi/4$, $a_4 = 1/2$, $a_4' = 1/2$, $b_4 = 1$, $b_4' = 1/2$ "
            "(red positive, blue negative, white zero; colour scale from $-3.5$ to "
            "$3.5$). Top left: the sum of the three inflating terms "
            "$\\gamma^\\mu\\Omega_\\mu$, $\\mu = x1, x2, x3$; top right: the sum of the "
            "three deflating terms, $\\mu = x5, x6, x7$; their $\\gamma^{(x4)}$ parts "
            "have opposite signs and sizes $0.75$ and $0.375$. Bottom left: the total "
            "over all eight directions; bottom right: $3H\\gamma^{(x0)} + "
            ...
            "\\frac34(b_4'/b_4)\\gamma^{(x4)}$. The two bottom pictures are identical; "
            "for a constant $b_4$ the faint $\\gamma^{(x4)}$ entries would vanish.")
```

The figure is saved; the cell prints two PASS lines and the file name.

What Figure 06a.7 shows. The two upper pictures contain the same pattern of $\gamma^{(x0)}$ with the value $\frac{3}{2}H = 1.5$ (two diagonal lines in the off-diagonal blocks), and on top of it the pattern of $\gamma^{(x4)}$ with opposite colours in the two pictures: entries $\pm\frac{3}{2}a_4' = \pm 0.75$ in the first and $\pm(\frac{3}{2}a_4' - \frac{3}{4}b_4'/b_4) = \pm 0.375$ in the second. In the total (lower left) the value on the two diagonal lines is 3, and only the faint $\gamma^{(x4)}$ entries $\pm\frac{3}{4}b_4'/b_4 = \pm 0.375$ remain; the lower right picture, $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$, is identical to it. For a constant b_4 the faint entries would vanish.

In [18], the divergence form (Section 6.9).

```
anticommutes = all(matrix_is_zero(gup[mu] * Omega[mu] + Omega[mu] * gup[mu])
                   for mu in range(8))
check(anticommutes, "{gamma^mu, Omega_mu} = 0 for each mu separately",
      record=f"{REPORT_PY}, check anticommutator_gamma_Omega_vanishes (b4 = 1)")
```

Fact 1: $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu = 0$ for each μ separately.

```
sqrt_g = b4 ** sp.Rational(3, 2) * sp.cos(z)  # sqrt|det g|
divergence = sum(((sqrt_g * gup[mu]).diff(x[mu]) for mu in range(8)), Z16) / (2 * sqrt_g)
check(matrix_is_zero(divergence - gravity_term)
      and record_passed(REPORT_WL_B4, "gammaOmega_divergence_form")
      and record_passed(REPORT_LEAD, "gamma_Omega_divergence_formula"),
      "(1/(2 sqrt|g|)) d_mu (sqrt|g| gamma^mu) = 3 H gamma^(x0) + (3/4)(b4'/b4) "
      "gamma^(x4)",
      record=f"{REPORT_WL_B4}, check gammaOmega_divergence_form")
```

`divergence` is $\frac{1}{2\sqrt{|g|}}\sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)$ with $\sqrt{|g|} = b_4^{3/2}\cos z$; the check requires it to equal $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$, the WolframScript report with b_4 to record the same, and the lead's report to record the form at $b_4 = 1$.

```
products = [sp.simplify(sp.prod([f[c] for c in range(8) if c != b])) for b in range(8)]
for b in (0, 4):
```

```
    say(f"product of the f_c with c != {NAMES[b]}: {products[b]}")
own_coordinate = [sp.simplify(sp.diff(products[b], x[b]) / (2 * sqrt_g))
                  for b in range(8)]
say("(1/(2 sqrt|g|)) d_b (product without b), b = x0 ... x7: "
    f"{own_coordinate}")
expected_own = [3 * H, 0, 0, 0, sp.Rational(3, 4) * b4p / b4, 0, 0, 0]
check(all(is_zero(own_coordinate[b] - expected_own[b]) for b in range(8)),
      "only the hidden direction (3 H) and the time ((3/4) b4'/b4) contribute")
```

Fact 2: `products[b]` is the product of the seven factors other than f_b. The two interesting ones are printed, `b4(x4)**(3/2)*sin(6*H*x0)` for $b = x0$ and `b4(x4)**(3/2)*cos(6*H*x0)` for $b = x4$. `own_coordinate` divides the derivative of each product with respect to its own coordinate by $2\sqrt{|g|}$; the printed list is `[3*H, 0, 0, 0, 3*Derivative(b4(x4), x4)/(4*b4(x4)), 0, 0, 0]`, and the check requires exactly this: only the hidden direction contributes, with $3H$, and the time, with $\frac{3}{4}b_4'/b_4$.

In [19], central differences and figure 8.

```
H_value = 1.0
x0_values = np.linspace(0.002, np.pi / 12 - 0.002, 300)  # z = 6 x0 inside (0, pi/2)
step = 1e-5  # the step h of the central difference
```

Numbers instead of symbols: $H = 1$, 300 values of x_0 inside $(0, \pi/12)$ (so that $z = 6x_0$ lies inside $(0, \pi/2)$), and the step $h = 10^{-5}$.

```
def hidden_density(x0_value):
    return np.sin(6 * H_value * x0_value)  # sqrt|g| e_(x0)^x0 / b4^(3/2) = sin z
```

The hidden density $\sqrt{|g|}\, {e_{(x0)}}^{x0}$ divided by $b_4^{3/2}$, $\cos z \tan z = \sin z$, as a numerical function (the factor $b_4^{3/2}$ does not depend on x_0 and cancels in the quotient).

```
derivative = (hidden_density(x0_values + step)
              - hidden_density(x0_values - step)) / (2 * step)
ratio = derivative / (2 * np.cos(6 * H_value * x0_values))  # should be 3 H = 3
x4_values = np.linspace(-6.0, 6.0, 300)

def b4_history(x4_value):
    return 1.0 + 0.5 * np.sin(x4_value)  # an illustrative b4(x4) > 0

def time_density(x4_value):
    return b4_history(x4_value) ** 1.5  # sqrt|g| e_(x4)^x4 / cos z = b4^(3/2)

time_derivative = (time_density(x4_values + step)
                   - time_density(x4_values - step)) / (2 * step)
time_ratio = time_derivative / (2 * time_density(x4_values))  # (1/(2 b4^1.5)) d b4^1.5
exact_time = 0.75 * 0.5 * np.cos(x4_values) / b4_history(x4_values)  # (3/4) b4'/b4
```

```
report("largest |central difference - 3 H| over the grid",
       f"{np.max(np.abs(ratio - 3.0)):.1e}")
report("largest |central difference - (3/4) b4'/b4| over the grid",
       f"{np.max(np.abs(time_ratio - exact_time)):.1e}")
check(np.max(np.abs(ratio - 3.0)) < 1e-6
      and np.max(np.abs(time_ratio - exact_time)) < 1e-6,
      "the numerical derivatives give 3 H and (3/4) b4'/b4")
```

The **central difference** $(F(x_0 + h) - F(x_0 - h))/(2h)$ approximates the derivative $F'(x_0)$ with an error of about $\frac{h^2}{6}F'''$; divided by $2\cos z$ it should be $3H = 3$. For the time direction `b4_history` is the illustrative $b_4(x_4) = 1 + \frac{1}{2}\sin x_4$ on 300 times from -6 to 6, and `time_density` is the time density divided by $\cos z$, $b_4^{3/2}$ (`** 1.5` is the power $\frac{3}{2}$). Its central difference, divided by $2b_4^{3/2}$, should be the exact `exact_time`, $\frac{3}{4}b_4'/b_4 = \frac{3}{4}\cdot\frac{\frac{1}{2}\cos x_4}{1+\frac{1}{2}\sin x_4}$. The two RESULT lines print the largest deviations, 1.9e-09 and 2.5e-11, and the check requires both to be below 10^{-6}. For $F = \sin 6x_0$ the error estimate is $\frac{h^2}{6}\cdot 216\cos z/(2\cos z) = 18h^2 = 1.8\times 10^{-9}$, the printed size; the time derivatives of $b_4^{3/2}$ are of size 1, so its error is about 10^{-11}.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
zz = 6 * H_value * x0_values
ax_left.plot(zz, ratio, label="$\\partial_{x0}(b_4^{3/2}\\sin z)/"
                              "(2b_4^{3/2}\\cos z)$")

ax_left.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax_left.set_ylabel("coefficient of $\\gamma^{(x0)}$ (units of $H$)")
ax_left.set_title("Hidden direction: the constant $3H$")
ax_left.legend(fontsize=8, loc="lower center")
ax_right.plot(x4_values, time_ratio,
              label="central difference, $b_4 = 1 + \\frac{1}{2}\\sin x_4$")
ax_right.plot(x4_values, exact_time, ":", color="black", linewidth=2.5,
              label="exact $\\frac{3}{4} b_4'/b_4$")
ax_right.plot(x4_values, np.zeros_like(x4_values), "--", color="gray",
              label="$b_4 = 1$: exactly $0$")
```

The left panel draws the numerical coefficient of $\gamma^{(x0)}$ versus z.

```
ax_right.set_ylim(-1.05, 0.6)  # room for the legend below the curves
ax_right.set_xlabel("time $x_4$ (units $1/H$)")
ax_right.set_ylabel("coefficient of $\\gamma^{(x4)}$")
ax_right.set_title("Time direction: $\\frac{3}{4} b_4'/b_4$")
ax_right.legend(fontsize=8, loc="lower center")
```

The right panel draws the numerical coefficient of $\gamma^{(x4)}$ for the illustrative history (solid), the exact $\frac{3}{4}b_4'/b_4$ (dotted) and the zero of $b_4 = 1$ (dashed) versus the time; `set_ylim(-1.05, 0.6)` leaves room for the legend below the curves.

```
save_figure(fig, "divergence_form",
            "The divergence form of $\\gamma^\\mu\\Omega_\\mu$, with $H = 1$, checked "
            "by central differences with step $10^{-5}$. Left: the coefficient of "
```

```
"$\\gamma^{(x0)}$, $\\partial_{x0}(b_4^{3/2}\\sin z)/(2b_4^{3/2}\\cos z)$, "
"versus the hidden angle $z$ in radians: the constant $3$ for every $z$. "

...
"(dashed): the time direction contributes only through a changing $b_4$.")
```

The figure is saved; the cell prints the RESULT line, the PASS line and the file name.

What Figure 06a.8 shows. On the left, the solid line is flat at 3 over the whole range of z: the coefficient of $\gamma^{(x0)}$ is the constant $3H$. On the right, the solid central differences lie on the dotted exact curve $\frac{3}{4}b_4'/b_4$, which oscillates between about -0.43 and 0.43 with the illustrative b_4; for $b_4 = 1$ the coefficient is the dashed 0. The time direction contributes only through a changing b_4.

In [20], the Dirac operator written out (Section 6.10).

```
import re  # text patterns, to rename the record's symbols

psi = sp.Matrix([sp.Function(f"psi{A}")(*x) for A in range(1, 17)])  # 16 functions
D = [psi.diff(x[mu]) + Omega[mu] * psi for mu in range(8)]  # D_mu Psi
dirac = sum((gup[mu] * D[mu] for mu in range(8)), sp.zeros(16, 1))
written_out = sum((gamma[a] * psi.diff(x[a]) / f[a] for a in range(8)),
                  sp.zeros(16, 1)) + gravity_term * psi
check(all(is_zero(v) for v in dirac - written_out)
      and record_passed(REPORT_WL_B4, "Dirac_operator_explicit_C"),
      "gamma^mu D_mu Psi = sum_a (1/f_a) gamma^a d_a Psi + 3 H gamma^(x0) Psi + "
      "(3/4)(b4'/b4) gamma^(x4) Psi",
      record=f"{REPORT_WL_B4}, check Dirac_operator_explicit_C")
```

`re` is Python's module for text patterns. `psi` is a column of sixteen unknown functions $\psi_1, \ldots, \psi_{16}$ of all eight coordinates (`sp.Function(f"psi{A}")(*x)` makes the function named psi1, psi2, ... with the eight arguments). `D` is the list of the eight covariant derivatives $\partial_\mu\Psi + \Omega_\mu\Psi$, `dirac` is $\sum_\mu \gamma^\mu D_\mu\Psi$, and `written_out` is $\sum_a f_a^{-1}\gamma^{(a)}\partial_a\Psi + (3H\gamma^{(x0)} + \frac{3}{4}\frac{b_4'}{b_4}\gamma^{(x4)})\Psi$. The check requires the sixteen differences to vanish and the WolframScript report with b_4 to record `Dirac_operator_explicit_C` as passed.

```
# Rename the derivatives d psi_B / d x_k and then the functions psi_B as plain
# symbols dPsi<B>x<k> and Psi<B> (derivatives first: renaming psi_B first would
# turn its derivatives into derivatives of a constant symbol, which are zero).
rename_derivatives = {sp.Derivative(psi[B], x[k]): sp.Symbol(f"dPsi{B + 1}x{k}")
                      for B in range(16) for k in range(8)}
rename_functions = {psi[B]: sp.Symbol(f"Psi{B + 1}") for B in range(16)}
```

To compare with the records' sixteen equations, the derivatives $\partial\psi_B/\partial x_k$ are renamed as plain symbols `dPsi<B>x<k>` (with the number k of the coordinate x_k, 0 to 7) and the functions as `Psi<B>`. The order matters, as the comment says: renaming the functions first would turn their derivatives into derivatives of constants, which are zero.

```
def same_components(equations, at_b4_equal_1):
    same = True
    for A, equation in enumerate(equations):
        left = equation.split("==")[0]  # the record: left side == V*Psi[A]
        left = left.replace(chr(34), "")  # chr(34) is the double-quote character
        # dd[x4, Psi[14]] (the derivative of Psi_14 by x4) becomes dPsi14x4:
        left = re.sub(r"dd\[x(\d), Psi\[(\d+)\]\]", r"dPsi\2x\1", left)
        left = re.sub(r"Psi\[(\d+)\]", r"Psi\1", left)
        record_left = wolfram_to_sympy(left, RECORD_NAMES)
        mine = dirac[A].subs(rename_derivatives).subs(rename_functions)
        if at_b4_equal_1:
            mine = at_b4_1(mine)
        same = same and is_zero(mine - record_left)
    return same

check(same_components(FORMULAS_B4["field_equation_components"], False)
      and same_components(FORMULAS["field_equation_components"], True),
```

`same_components(equations, at_b4_equal_1)` compares the sixteen equations of one record with the notebook's. For each record equation (`enumerate` numbers them from 0) the text left of `==` is taken (the right side is $V\Psi_A$ and not needed). `chr(34)` is the double-quote character, which is removed. The pattern `dd\[x(\d), Psi\[(\d+)\]\]` matches texts such as `dd[x4, Psi[14]]`, the derivative of ψ_{14} by x_4; `\d` is a digit, `\d+` one or more digits, the parentheses capture them, and `re.sub` replaces the match by `dPsi14x4` (`\2` and `\1` insert the captured numbers). The second pattern turns `Psi[9]` into `Psi9`. The text is read with `wolfram_to_sympy`, and the notebook's component `A` with the same renaming (at $b_4 = 1$ when the second argument asks for it) must agree with it exactly.

```
      "all 16 components of the Dirac operator equal the records (with b4, and at "
      "b4 = 1)",
      record=f"{THEORY_B4_FILE} and {THEORY_FILE}, formula field_equation_components")
c_b4 = sp.Rational(3, 4) * b4p / b4  # the coefficient of gamma^(x4)
square = (gravity_term * gravity_term - (9 * H**2 - c_b4**2) * I16)
ranks = [(gamma[0] + sign * gamma[4]).rank() for sign in (1, -1)]
report("ranks of gamma^(x0) + gamma^(x4) and gamma^(x0) - gamma^(x4)", ranks)
both_fields = all(record_passed(REPORT_WL, name) for name in [
    "nontriviality_1_dirac16complex", "nontriviality_2_dirac16complex00"])
check(matrix_is_zero(square) and gamma[0] * gamma[0] == I16 and ranks == [8, 8]
      and both_fields and record_passed(REPORT_PY_B4, "gravity_term_square_b4"),
      "M M = (9 H^2 - (9/16)(b4'/b4)^2) 1: M Psi = 0 only for Psi = 0 unless "
      "|b4'/b4| = 4 H (always for constant b4), and there M has rank 8",
      record=f"{REPORT_PY_B4}, check gravity_term_square_b4; {REPORT_WL}, checks "
             "nontriviality_1_dirac16complex and nontriviality_2_dirac16complex00")
```

The first check requires all sixteen components to agree with both records: with b_4 as they are, and at $b_4 = 1$. Then the non-triviality of Section 6.10. `c_b4` is $\frac{3}{4}b_4'/b_4$, and `square` is $MM - (9H^2 - c^2)\,1$ for the matrix $M =$ `gravity_term`, which must be the zero matrix. `ranks` holds the exact ranks of $\gamma^{(x0)} + \gamma^{(x4)}$ and $\gamma^{(x0)} - \gamma^{(x4)}$ (`.rank()` computes the rank exactly, by elimination with fractions); the RESULT line prints `[8, 8]`. `both_fields` is `True` when the WolframScript report `wolfram-field-theory.json` (the name `REPORT_WL` of In [3]) records both of its non-triviality checks, made

at $b_4 = 1$, as passed: `nontriviality_1_dirac16complex` for the Grassmann field and `nontriviality_2_dirac16complex00` for the commuting field (`all(...)` is `True` when every item of the list is). The last check requires the square, $(\gamma^{(x0)})^2 = 1$, the two ranks 8, both non-triviality checks and the check `gravity_term_square_b4` of the sympy report with b_4: the term vanishes only for $\Psi = 0$ unless $|b_4'/b_4| = 4H$, and there M has rank 8. Its second printed line names the record checks it consulted. The cell prints three PASS lines with their records and one RESULT line.

In [21], figure 9.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
coefficient = [sp.lambdify(X4_SYMBOL, (1 / fa).subs(history).subs(
    {H: 1, x0: sp.pi / 24})) for fa in f]
```

The eight factors $1/f_a$ in front of the derivatives, as numerical functions of the time for the illustrative history $a_4 = x_4$, $b_4 = 1$, at $z = \pi/4$.

```
ax_left.semilogy(times, coefficient[1](times),
                 label="$1/f_1 = e^{-a_4}/s$ (3-space derivatives)")
ax_left.semilogy(times, coefficient[5](times), "--",
                 label="$1/f_5 = e^{a_4}b_4^{-1/2}/s$ (extra-time derivatives)")
ax_left.semilogy(times, np.ones_like(times), ":", color="black",
                 label="$1/f_4 = 1$ (time derivative)")
ax_left.set_xlabel("time $x_4$ (units $1/H$), history $a_4 = x_4$, $b_4 = 1$")
ax_left.set_ylabel("factor in front of the derivative (log axis)")
ax_left.set_title("Where the deflation enters the field equation")
ax_left.legend(fontsize=8)
```

The left panel, on a logarithmic axis: $1/f_1 = e^{-a_4}/s$ (solid), $1/f_5 = e^{a_4} b_4^{-1/2}/s$ (dashed) and $1/f_4 = 1$ (dotted).

```
zz = np.linspace(0.05, np.pi / 2 - 0.15, 300)
ax_right.plot(zz, np.tan(zz), label="$1/f_0 = \\tan z$ (hidden derivative)")
ax_right.plot(zz, np.sin(zz) ** (-1 / 6), "--",
              label="$1/s = \\sin^{-1/6} z$ (warped directions, $a_4 = 0$)")
ax_right.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax_right.set_ylabel("factor (pure number)")
ax_right.set_title("Dependence on the hidden direction")
ax_right.legend(fontsize=8)
```

The right panel, versus z: $1/f_0 = \tan z$ and $1/s = \sin^{-1/6} z$; the range stops at $\pi/2 - 0.15$ because $\tan z$ grows without bound at $\pi/2$.

```
save_figure(fig, "derivative_coefficients",
            "The factors $1/f_a$ in front of the derivatives in the Dirac operator "
            ...
            "the six warped directions.")
```

The figure is saved; the cell prints the file name.

What Figure 06a.9 shows. On the left the two warped factors are straight lines of opposite slope: the factor in front of the 3-space derivatives falls and the factor in front of the extra-time derivatives rises as a_4 grows. This is how the deflation of the extra times enters the field equation, although it does not enter $\gamma^\mu \Omega_\mu$. On the right, the hidden factor $\tan z$ rises steeply towards the patch end, while $\sin^{-1/6} z$ is large only very near the tip.

In [22], the negative control (Section 6.10).

```
f_control = ([sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
             + [sp.exp(a4) * s] * 3)  # extra times INFLATING, b4 = 1
g_control = sp.diag(*[ETA[a] * f_control[a] ** 2 for a in range(8)])
e_control = sp.diag(*f_control)
Gam_control = christoffel(g_control, x)
omega_control = spin_connection(e_control, Gam_control, x, ETA)
Omega_control = spinor_connection(omega_control, S)
gup_control = curved_gammas(e_control, gamma)
slash_control = sum((gup_control[mu] * Omega_control[mu] for mu in range(8)), Z16)
```

The same computation for the control metric at $b_4 = 1$: the factors of the extra times are $e^{+a_4} s$ instead of $e^{-a_4} s$, and everything else (metric, vielbein, Christoffel symbols, spin connection, spinor connection, curved gammas, contraction) is computed by the same four functions.

```
alpha_control = sp.simplify(-(slash_control * gamma[4]).trace() / 16)
beta_control = sp.simplify((slash_control * gamma[0]).trace() / 16)
report("control: coefficient of gamma^(x4)", alpha_control)
report("control: coefficient of gamma^(x0)", beta_control)
```

The two coefficients of the control contraction, found with traces, are printed: `3*Derivative(a4(x4), x4)` and `3*H`.

```
lead = json.loads(repository_file(REPORT_LEAD).read_text(encoding="utf-8"))
detail = [c["detail"] for c in lead["checks"]
          if c["name"] == "negative_control_inflating_extra_times"][0]
```

The lead's report is read, and `detail` is the detail text of its check `negative_control_inflating_extra_times` (the list comprehension keeps the one matching check, and `[0]` takes it).

```
check(matrix_is_zero(slash_control - alpha_control * gamma[4] - beta_control * gamma[0])
      and is_zero(alpha_control - 3 * sp.Derivative(a4, x4))
      and is_zero(beta_control - 3 * H)
      and "(3*Derivative(a4(x4), x4)) gamma^(x4)" in detail
      and record_passed(REPORT_LEAD, "negative_control_inflating_extra_times"),
      "control with inflating extra times: 3 a4' gamma^(x4) + 3 H gamma^(x0)",
      record=f"{REPORT_LEAD}, check negative_control_inflating_extra_times")
```

The check requires the control contraction to be exactly $3a_4'\gamma^{(x4)} + 3H\gamma^{(x0)}$ with nothing left over, the lead's detail text to contain the same coefficient, and the lead's check to be recorded as passed. The cell prints two RESULT lines and one PASS line.

In [23], figure 10.

```
rates = np.linspace(-2.0, 2.0, 81)  # values of a4'
rate_symbol = sp.Symbol("rate")
author_alpha = sp.lambdify(rate_symbol, sp.simplify(at_b4_1(sum(
    a for a, _ in per_direction))).subs(a4p, rate_symbol))
control_alpha = sp.lambdify(rate_symbol, alpha_control.subs(
    sp.Derivative(a4, x4), rate_symbol))
```

81 rates a_4' from -2 to 2. The total time coefficient of the author's metric at $b_4 = 1$ (0) and of the control ($3a_4'$) become numerical functions of the rate (the derivative a_4' is replaced by the plain symbol `rate`).

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
ax_left.plot(rates, np.broadcast_to(author_alpha(rates), rates.shape),
             label="author: deflating extra times")
ax_left.plot(rates, np.broadcast_to(control_alpha(rates), rates.shape), "--",
             label="control: inflating extra times")
ax_left.set_xlabel("rate $a_4'$ (units of $H$)")
ax_left.set_ylabel("coefficient of $\\gamma^{(x4)}$ (units of $H$)")
ax_left.set_title("The time-direction term")
ax_left.legend(fontsize=8)
```

The left panel: the author's coefficient (solid) and the control's (dashed) versus the rate. `np.broadcast_to` turns the author's constant 0 into a list of 81 zeros.

```
ax_right.plot(rates, np.full_like(rates, float(hidden.subs(H, 1))),
              label="author: deflating extra times")
ax_right.plot(rates, np.full_like(rates, float(beta_control.subs(H, 1))), "--",
              label="control: inflating extra times")
ax_right.set_ylim(0.0, 4.0)
ax_right.set_xlabel("rate $a_4'$ (units of $H$)")
ax_right.set_ylabel("coefficient of $\\gamma^{(x0)}$ (units of $H$)")
ax_right.set_title("The hidden-direction term (identical lines)")
ax_right.legend(fontsize=8)
```

The right panel: the hidden coefficient $3H$ with $H = 1$ for both metrics (`np.full_like` makes a list of 81 equal values).

```
save_figure(fig, "negative_control",
            "The negative control, at $b_4 = 1$. Left: the coefficient of "
            "$\\gamma^{(x4)}$ in $\\gamma^\\mu\\Omega_\\mu$ versus the rate $a_4'$, "
            "both in units of $H = 1$, for the author's metric with deflating extra "
            "times (solid, zero for every rate) and for a control metric with "
            "inflating extra times (dashed, "
            "the line $3a_4'$). Right: the coefficient of $\\gamma^{(x0)}$, $3H$ in "
            ...
            "of the time-direction terms is caused by the deflation.")
```

The figure is saved; the cell prints the file name.

What Figure 06a.10 shows. On the left, the author's line lies flat on 0 for every rate, while the control's line rises through the origin with slope 3. On the right, the two lines lie on top of each other at 3. The deflation of the extra times is exactly what cancels the a_4' terms along the time; the hidden-direction term does not care whether the extra times deflate or inflate.

In [24], the last checks.

```
cited = {

```

```
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected),
      "all ten figure files exist")
all_checks_passed()
```

The names of the ten figure files (`enumerate(..., 1)` numbers them from 1); the check requires all ten to exist, and `all_checks_passed()` prints the last line, ALL 36 CHECKS PASSED (notebook 06a).

6.15 Changing the frame: local spin covariance

Section 6.2 showed that the vielbein is a choice: for every point-dependent matrix $\Lambda(x)$ with $\Lambda^T\eta\Lambda = \eta$ the frame $e' = \Lambda e$ describes the same metric. Physics must not depend on this choice. This section derives how the spin connection, the spinor connection, the curved gammas and the contraction $\gamma^\mu\Omega_\mu$ change when the frame is changed. Matrices are written without indices: for each μ, ω_μ is the 8×8 matrix with the entries $\omega_\mu{}^a{}_b$ (row a, column b), and e_ν is the column of the eight numbers $e^a{}_\nu$.

The spin connection of the new frame. In this notation the vielbein postulate of Section 6.4 reads $\partial_\mu e_\nu - \sum_\lambda \Gamma^\lambda{}_{\mu\nu} e_\lambda + \omega_\mu e_\nu = 0$. The new frame describes the same metric, so it has the same Christoffel symbols. Its postulate, with $e'_\nu = \Lambda e_\nu$:

$$\partial_\mu(\Lambda e_\nu) - \sum_\lambda \Gamma^\lambda{}_{\mu\nu}\Lambda e_\lambda + \omega'_\mu \Lambda e_\nu = (\partial_\mu\Lambda)e_\nu + \Lambda\Big(\partial_\mu e_\nu - \sum_\lambda \Gamma^\lambda{}_{\mu\nu} e_\lambda\Big) + \omega'_\mu\Lambda e_\nu$$

(the product rule; Λ taken out of the sum)

$$= (\partial_\mu\Lambda)e_\nu - \Lambda\omega_\mu e_\nu + \omega'_\mu\Lambda e_\nu = 0$$

(the old postulate replaces the bracket by $-\omega_\mu e_\nu$). The eight columns e_ν form an invertible matrix, so the matrix in front of them vanishes: $\partial_\mu\Lambda - \Lambda\omega_\mu + \omega'_\mu\Lambda = 0$, and multiplying from the right by Λ^{-1}:

$$\omega'_\mu = \Lambda\,\omega_\mu\,\Lambda^{-1} - (\partial_\mu\Lambda)\Lambda^{-1}.$$

The first term turns the old connection with the frame. The second term is new: it is the rate at which the frame is turned from point to point. The spin connection is not a tensor in its frame indices.

The spinor connection of the new frame. When the frame is turned by Λ, the spinor components change by a spin transformation $R(x)$ that **covers** Λ (Chapter 5): $R^{-1}\gamma^a R = \sum_c \Lambda^a{}_c\gamma^c$ for every a, or, inverted, $R\gamma^c R^{-1} = \sum_d (\Lambda^{-1})^c{}_d\gamma^d$. The new components are $\Psi' = R\Psi$. Covariance demands that the covariant derivative of the new components be the new components of the covariant derivative, $D'_\mu(R\Psi) = R\,D_\mu\Psi$ for every Ψ. Write it out:

$$\partial_\mu(R\Psi) + \Omega'_\mu R\Psi = (\partial_\mu R)\Psi + R\,\partial_\mu\Psi + \Omega'_\mu R\Psi \qquad \text{must equal} \qquad R\,\partial_\mu\Psi + R\,\Omega_\mu\Psi$$

(the product rule on the left). The terms $R\,\partial_\mu\Psi$ agree, so $(\partial_\mu R)\Psi + \Omega'_\mu R\Psi = R\Omega_\mu\Psi$ for every Ψ, that is $\partial_\mu R + \Omega'_\mu R = R\Omega_\mu$, and multiplying from the right by R^{-1}:

$$\Omega'_\mu = R\,\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}.$$

Theorem (local spin covariance). The canonical spinor connection of the frame $e' = \Lambda e$ is exactly this matrix. Proof, line by line. By the uniqueness of Section 6.7 it suffices to show that $X_\mu = R\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}$ has the defining property with the new connection ω'_μ, and trace 0. First part of X_μ:

$$\begin{aligned}[R\Omega_\mu R^{-1}, \gamma^a] &= R\,[\Omega_\mu, R^{-1}\gamma^a R]\,R^{-1} = \sum_c \Lambda^a{}_c\, R[\Omega_\mu, \gamma^c]R^{-1} \\ &= -\sum_{c,b} \Lambda^a{}_c\,\omega_\mu{}^c{}_b\, R\gamma^b R^{-1} = -\sum_d \left(\Lambda\omega_\mu\Lambda^{-1}\right)^a{}_d\gamma^d\end{aligned}$$

(multiply out both sides of the first equality; the covering relation; the defining property of Ω_μ; the inverted covering relation and the rule of matrix multiplication). Second part: differentiate the covering relation $R^{-1}\gamma^a R = \sum_c \Lambda^a{}_c\gamma^c$ with the product rule, using $\partial_\mu(R^{-1}) = -R^{-1}(\partial_\mu R)R^{-1}$ (differentiate $R^{-1}R = 1$):

$$-R^{-1}(\partial_\mu R)R^{-1}\gamma^a R + R^{-1}\gamma^a\,\partial_\mu R = \sum_c (\partial_\mu \Lambda^a{}_c)\gamma^c.$$

Multiply from the left by R and from the right by R^{-1}:

$$-(\partial_\mu R)R^{-1}\gamma^a + \gamma^a(\partial_\mu R)R^{-1} = \sum_c (\partial_\mu\Lambda^a{}_c)R\gamma^c R^{-1} = \sum_d \left((\partial_\mu\Lambda)\Lambda^{-1}\right)^a{}_d\gamma^d.$$

The left side is $[-(\partial_\mu R)R^{-1}, \gamma^a]$. Adding the two parts:

$$[X_\mu, \gamma^a] = -\sum_d \left(\Lambda\omega_\mu\Lambda^{-1} - (\partial_\mu\Lambda)\Lambda^{-1}\right)^a{}_d\gamma^d = -\sum_d \omega'^{\,a}_{\mu\;d}\,\gamma^d.$$

The trace of $R\Omega_\mu R^{-1}$ is that of Ω_μ, which is 0 ($\mathrm{tr}(ABA^{-1}) = \mathrm{tr}(BA^{-1}A)$). The trace of $(\partial_\mu R)R^{-1}$ is the derivative of $\ln\det R$, a standard fact of linear algebra (Jacobi's formula, quoted without proof here, ASSUMED), and $\det R = 1$ for every element of Pin(4,4) (Chapter 5), so it is 0. For the one frame change used below this trace is also computed directly. □

The curved gammas and the contraction. The new inverse vielbein is $e'^{\,\mu}_a = \sum_c e_c{}^\mu(\Lambda^{-1})^c{}_a$ (the inverse of Λe is $e^{-1}\Lambda^{-1}$). Hence

$$\gamma'^\mu = \sum_a e'^{\,\mu}_a\gamma^a = \sum_c e_c{}^\mu \sum_a (\Lambda^{-1})^c{}_a\gamma^a = \sum_c e_c{}^\mu\, R\gamma^c R^{-1} = R\,\gamma^\mu R^{-1}$$

(the inverted covering relation). Multiply with Ω'_μ and sum over μ:

$$\sum_\mu \gamma'^\mu \Omega'_\mu = \sum_\mu R\gamma^\mu R^{-1}\big(R\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}\big) = R\Big(\sum_\mu \gamma^\mu \Omega_\mu\Big)R^{-1} - \sum_\mu \gamma'^\mu (\partial_\mu R)R^{-1}$$

($R^{-1}R = 1$ in the first product; $R\gamma^\mu R^{-1} = \gamma'^\mu$ in the second). The first term only turns the old contraction; **the second term can change it completely**. The contraction $\gamma^\mu\Omega_\mu$ is **frame-dependent**.

statement	**status**	**where it is verified**
$\omega'_\mu = \Lambda\omega_\mu\Lambda^{-1} - (\partial_\mu\Lambda)\Lambda^{-1}$	PROVED (above)	the boosted frame of Section 6.16: `python-scope.json` and `wolfram-scope.json`, check `boosted_frame_canonical_connection`
local spin covariance $\Omega'_\mu = R\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}$, $\gamma'^\mu = R\gamma^\mu R^{-1}$	PROVED (above, with Jacobi's formula quoted)	Notebook 06b checks both for all eight μ in the boosted frame, In [12]

The two scope reports lie in `Revision/theory/reports`; they were written by two programs that share no code (a sympy program and a WolframScript program).

6.16 A boost in the plane of $x4$ and $x0$

The boost. Mix the time $x4$ (time-like) and the hidden direction $x0$ (space-like) with the **rapidity** b:

$$e'^{(x4)} = \cosh b\, e^{(x4)} + \sinh b\, e^{(x0)}, \qquad e'^{(x0)} = \sinh b\, e^{(x4)} + \cosh b\, e^{(x0)},$$

and keep the other six frame directions. Here $\cosh b = (e^b + e^{-b})/2$ and $\sinh b = (e^b - e^{-b})/2$ (Chapter 5), with $\cosh^2 b - \sinh^2 b = 1$. The matrix $\Lambda(b)$ is the identity except in the rows and columns of $x4$ and $x0$, where it is $\begin{pmatrix}\cosh b & \sinh b\\ \sinh b & \cosh b\end{pmatrix}$. In these two rows and columns η is $\mathrm{diag}(-1,+1)$, and

$$\Lambda^T\eta\Lambda = \begin{pmatrix}\cosh b & \sinh b\\ \sinh b & \cosh b\end{pmatrix}\begin{pmatrix}-\cosh b & -\sinh b\\ \sinh b & \cosh b\end{pmatrix}$$

(Λ is symmetric, so $\Lambda^T = \Lambda$; and $\eta\Lambda$ is Λ with the sign of its first row changed)

$$= \begin{pmatrix}-\cosh^2 b + \sinh^2 b & -\cosh b\sinh b + \sinh b\cosh b\\ -\sinh b\cosh b + \cosh b\sinh b & -\sinh^2 b + \cosh^2 b\end{pmatrix} = \begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}$$

(multiply row by column; then $\cosh^2 - \sinh^2 = 1$). So $\Lambda(b)$ keeps η for every b, and $e' = \Lambda(b)e$ is a vielbein of the author's metric. A rotation moves a direction along a circle; a boost moves it along a **hyperbola**, keeping $t^2 - y^2$ (figure 06b.1). Now let the rapidity grow with the time,

$$b = \beta x_4 + b_0,$$

with two constants β (the rate) and b_0 (the starting value).

The spinor boost. Put $X = \gamma^{(x4)}\gamma^{(x0)}$. Then

$$X^2 = \gamma^{(x4)}\gamma^{(x0)}\gamma^{(x4)}\gamma^{(x0)} = -\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)}\gamma^{(x0)} = -(-1)(+1) = 1$$

(exchange the two middle factors at the cost of a sign; then the Clifford relation twice). With $c = \cosh\frac{b}{2}$ and $s = \sinh\frac{b}{2}$ define $R = c - sX$; its inverse is $R^{-1} = c + sX$, because $(c - sX)(c + sX) = c^2 - s^2X^2 = c^2 - s^2 = 1$. Chapter 5 showed that R is the spinor boost $\exp(-\frac{b}{2}X)$ in the plane $(x4, x0)$. X anticommutes with $\gamma^{(x4)}$ and with $\gamma^{(x0)}$ (moving either through the product of two gammas meets one equal and one different factor: one sign) and commutes with the other six gammas (two signs). Hence $R^{-1}\gamma^c R = \gamma^c$ for the six other directions, and for $x4$:

$$R^{-1}\gamma^{(x4)} = (c + sX)\gamma^{(x4)} = \gamma^{(x4)}(c - sX) = \gamma^{(x4)}R$$

(move $\gamma^{(x4)}$ to the left through X at the cost of a sign), so

$$\begin{aligned} R^{-1}\gamma^{(x4)}R = \gamma^{(x4)}R^2 &= \gamma^{(x4)}\big(c^2 + s^2 - 2cs\,X\big) \\ &= \cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x4)}X = \cosh b\,\gamma^{(x4)} + \sinh b\,\gamma^{(x0)} \end{aligned}$$

(multiply out $(c - sX)^2$ with $X^2 = 1$; the half-angle formulas $c^2 + s^2 = \cosh b$ and $2cs = \sinh b$ of Chapter 5; and $\gamma^{(x4)}X = \gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)} = -\gamma^{(x0)}$). In the same way $R^{-1}\gamma^{(x0)}R = \gamma^{(x0)}(\cosh b - \sinh b\,X) = \sinh b\,\gamma^{(x4)} + \cosh b\,\gamma^{(x0)}$, using $\gamma^{(x0)}X = \gamma^{(x0)}\gamma^{(x4)}\gamma^{(x0)} = -\gamma^{(x4)}$. These are the two rows of $\Lambda(b)$: R **covers the boost.**

The contraction in the boosted frame. By Sections 6.15 and 6.8, $\sum_\mu \gamma'^\mu\Omega'_\mu = R\big(3H\gamma^{(x0)} + c\,\gamma^{(x4)}\big)R^{-1} - \sum_\mu \gamma'^\mu(\partial_\mu R)R^{-1}$ with $c = \frac{3}{4}b'_4/b_4$. The first term, line by line:

$$R\gamma^{(x0)} = (c - sX)\gamma^{(x0)} = \gamma^{(x0)}(c + sX) = \gamma^{(x0)}R^{-1},$$

$$R\gamma^{(x0)}R^{-1} = \gamma^{(x0)}(c + sX)^2 = \gamma^{(x0)}(\cosh b + \sinh b\,X) = \cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}$$

(the same steps as before). Call $v = \cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}$, and $w = R\gamma^{(x4)}R^{-1} = \cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)}$ (the same steps once more; it is computed again just below); the first term is $3H\,v + c\,w$. The second term: R depends on x_4 only, through b, with $db/dx_4 = \beta$, so only $\mu = x4$ contributes:

$$\partial_4 R = \tfrac{\beta}{2}(s - cX), \qquad (\partial_4 R)R^{-1} = \tfrac{\beta}{2}(s - cX)(c + sX) = \tfrac{\beta}{2}\big(sc + s^2X - c^2X - csX^2\big) = -\tfrac{\beta}{2}X$$

(the chain rule, $\frac{d}{db}\cosh\frac{b}{2} = \frac{1}{2}\sinh\frac{b}{2}$ and $\frac{d}{db}\sinh\frac{b}{2} = \frac{1}{2}\cosh\frac{b}{2}$; multiply out; $X^2 = 1$, so $sc - cs = 0$ and $(s^2 - c^2)X = -X$). Its trace is 0, because X is a product of two different gammas. With $\gamma'^{x4} = R\gamma^{(x4)}R^{-1} = \gamma^{(x4)}(\cosh b + \sinh b\,X) = \cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)}$ (the same steps; $f_4 = 1$):

$$\gamma'^{x4}(\partial_4 R)R^{-1} = -\tfrac{\beta}{2}\big(\cosh b\,\gamma^{(x4)}X - \sinh b\,\gamma^{(x0)}X\big) = -\tfrac{\beta}{2}\big(-\cosh b\,\gamma^{(x0)} + \sinh b\,\gamma^{(x4)}\big) = \tfrac{\beta}{2}\,v$$

($\gamma^{(x4)}X = -\gamma^{(x0)}$ and $\gamma^{(x0)}X = -\gamma^{(x4)}$). Subtracting:

$$\sum_\mu \gamma'^\mu \Omega'_\mu = 3H\,v + c\,w - \tfrac{\beta}{2}\,v = \frac{6H-\beta}{2}\big(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}\big) + \frac{3}{4}\,\frac{b'_4}{b_4}\big(\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)}\big).$$

At $\beta = b_0 = 0$ (no boost) this is $3H\gamma^{(x0)} + \frac{3}{4}(b'_4/b_4)\gamma^{(x4)}$ again. For the rate $\beta = 6H$ the first term vanishes and only $\frac{3}{4}(b'_4/b_4)\,w$ remains: **for a constant b_4, in particular on the backgrounds $b_4 = 1$, the contraction vanishes identically at the rate $\beta = 6H$**, at every time and for every function a_4. For a changing b_4 no rate removes it: v and w are independent (their coefficients of $\gamma^{(x0)}$ and $\gamma^{(x4)}$ form a matrix with the determinant $\cosh^2 b - \sinh^2 b = 1$), so the sum is zero only when both coefficients $\frac{6H-\beta}{2}$ and $\frac{3}{4}b'_4/b_4$ vanish; the rescaling of Section 6.18 removes the whole contraction.

But the spinor connection does not vanish. For $\beta = 6H$: $\Omega'_{x4} = R\Omega_{x4}R^{-1} - (\partial_4 R)R^{-1} = 0 + 3H\,X = 3H\gamma^{(x4)}\gamma^{(x0)}$, which is not zero; $\Omega'_{x_i} = R\Omega_{x_i}R^{-1}$ and $\Omega'_{x_t} = R\Omega_{x_t}R^{-1}$ are not zero because R is invertible; only $\Omega'_{x0} = R\,0\,R^{-1} - 0 = 0$. In this frame, for a constant b_4, the field equation $\sum_\mu \gamma'^\mu D'_\mu \Psi' = (m + U')\Psi'$ contains no term $\gamma'^\mu \Omega'_\mu \Psi'$ at all, although the spinor connection is present in seven of the eight directions. The canonical spin connection of the boosted frame has 13 independent nonzero components (Notebook 06b, In [7], COMPUTED exactly).

statement	**status**	**where it is verified**
the boosted frame gives the author's metric; its canonical connection obeys the vielbein postulate	PROVED	Notebook 06b, In [7] (every b_4); at $b_4 = 1$: `python-scope.json` and `wolfram-scope.json`, checks `boosted_frame_reproduces_metric`, `boosted_frame_canonical_connection`
$\gamma'^\mu\Omega'_\mu = \frac{6H-\beta}{2}(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}) + \frac{3}{4}\frac{b'_4}{b_4}(\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)})$	PROVED	Notebook 06b, In [8]; at $b_4 = 1$: both scope reports, check `boosted_frame_gammaOmega_formula`
for $\beta = 6H$ the contraction is $\frac{3}{4}(b'_4/b_4)\,w$, zero for a constant b_4; $\Omega'_\mu \neq 0$ for $\mu = x1, \ldots, x7$	PROVED	Notebook 06b, In [10]; at $b_4 = 1$: both scope reports, check `boosted_frame_gammaOmega_vanishes`
R covers the boost; the pieces $3Hv + \frac{3}{4}\frac{b'_4}{b_4}w$ and $\frac{\beta}{2}v$	PROVED (above)	Notebook 06b, In [12] (its own checks)

6.17 What no frame can remove: the curvature

Sections 6.5 and 6.16 taught the same lesson twice: the spin connection, and even its contraction, can look different, or vanish, in another frame. What does not depend on the frame is **curvature**.

The Riemann and Ricci tensors. Chapter 3 defined the Riemann tensor

$$R^{\rho}{}_{\sigma\mu\nu} = \partial_\mu \Gamma^{\rho}{}_{\nu\sigma} - \partial_\nu \Gamma^{\rho}{}_{\mu\sigma} + \sum_{\lambda} \left(\Gamma^{\rho}{}_{\mu\lambda}\Gamma^{\lambda}{}_{\nu\sigma} - \Gamma^{\rho}{}_{\nu\lambda}\Gamma^{\lambda}{}_{\mu\sigma}\right),$$

the Ricci tensor $R_{\sigma\nu} = \sum_\rho R^{\rho}{}_{\sigma\rho\nu}$, its mixed form $R^{\mu}{}_{\nu} = \sum_\sigma g^{\mu\sigma} R_{\sigma\nu}$ and the Ricci scalar $R = \sum_\mu R^{\mu}{}_{\mu}$. A space is flat exactly when the Riemann tensor vanishes everywhere.

One component by hand: $R^{x0}{}_{x0} = -6H^2$. Put $\sigma = \nu = x0$ in the Ricci tensor and use the Christoffel symbols of Section 6.3. Write $u = \partial_0 \ln \cos z$ and $v = \Gamma^{x0}{}_{x0x0}$, and note that $\sum_\rho \Gamma^{\rho}{}_{\rho 0} = \partial_0 \ln \sqrt{|g|} = \partial_0 \ln \left(b_4^{3/2} \cos z\right) = u$ (Section 6.9; b_4 does not depend on x_0). The four terms of $R_{00} = \sum_\rho R^{\rho}{}_{0\rho 0}$ are:

$$\sum_{\rho} \partial_\rho \Gamma^{\rho}{}_{00} = \partial_0 v$$

(the only nonzero $\Gamma^{\rho}{}_{00}$ is $\rho = x0$; $\Gamma^{x4}{}_{00} = 0$ because f_0 does not depend on x_4);

$$-\partial_0 \sum_{\rho} \Gamma^{\rho}{}_{\rho 0} = -\partial_0 u$$

(the contracted symbol);

$$\sum_{\rho,\lambda} \Gamma^{\rho}{}_{\rho\lambda}\Gamma^{\lambda}{}_{00} = u\, v$$

(only $\lambda = x0$ has $\Gamma^{\lambda}{}_{00} \neq 0$);

$$-\sum_{\rho,\lambda} \Gamma^{\rho}{}_{0\lambda}\Gamma^{\lambda}{}_{\rho 0} = -\left(6H^2 \cot^2 z + v^2\right)$$

($\Gamma^{\rho}{}_{0\lambda}$ is nonzero only for $\rho = \lambda$: $H \cot z$ for the six warped directions and v for $x0$; each gives its square). With $\partial_0 = 6H \frac{d}{dz}$ (the chain rule), $u = -6H \tan z$, $\partial_0 u = -36H^2/\cos^2 z$, $v = -6H(\tan z + \cot z)$ (Section 6.3, written with $\frac{1}{\sin z \cos z} = \tan z + \cot z$) and $\partial_0 v = -36H^2\left(\frac{1}{\cos^2 z} - \frac{1}{\sin^2 z}\right)$ (the derivatives of $\tan z$ and $\cot z$ are $1/\cos^2 z$ and $-1/\sin^2 z$):

$$R_{00} = -36H^2\Big(\frac{1}{\cos^2 z} - \frac{1}{\sin^2 z}\Big) + \frac{36H^2}{\cos^2 z} + 36H^2 \tan z(\tan z + \cot z) - 6H^2 \cot^2 z - 36H^2(\tan z + \cot z)^2$$

(insert the four terms; $uv = (-6H \tan z)(-6H)(\tan z + \cot z)$)

$$= \frac{36H^2}{\sin^2 z} + 36H^2 \tan^2 z + 36H^2 - 6H^2 \cot^2 z - 36H^2\left(\tan^2 z + 2 + \cot^2 z\right)$$

(the terms with $1/\cos^2 z$ cancel; $\tan z \cot z = 1$; multiply out the square)

$$= \frac{36H^2}{\sin^2 z} - 36H^2 - 42H^2\cot^2 z = 36H^2(1+\cot^2 z) - 36H^2 - 42H^2\cot^2 z = -6H^2\cot^2 z$$

(the $\tan^2 z$ terms cancel; $1/\sin^2 z = 1+\cot^2 z$, which is $\sin^2+\cos^2 = 1$ divided by $\sin^2 z$). Finally $R^{x0}{}_{x0} = g^{00}R_{00} = \tan^2 z\cdot(-6H^2\cot^2 z) = -6H^2$ (the inverse metric is diagonal, so only R_{00} enters). It is negative for every $H>0$ and all functions a_4 and b_4: **the author's metric is never flat.**

A second component by hand: $R^{x4}{}_{x4}$. This is the component that carries the deflation, so it is worth the four lines. Put $\sigma=\nu=x4$ in the same four terms. Every $\Gamma^{\rho}{}_{44}$ vanishes (case (a) of Section 6.3 gives $\partial_4 \ln f_4 = 0$ because $f_4 = 1$, and case (c) gives a multiple of $\partial_\rho f_4 = 0$), so the first and the third term vanish:

$$\sum_{\rho} \partial_\rho \Gamma^{\rho}{}_{44} = 0, \qquad \sum_{\rho,\lambda} \Gamma^{\rho}{}_{\rho\lambda}\Gamma^{\lambda}{}_{44} = 0.$$

The contracted symbol is $\sum_\rho \Gamma^{\rho}{}_{\rho 4} = 3a_4' + 3\alpha_t + 0 + \partial_4 \ln f_0 = 3a_4' + 3\alpha_t$ (three 3-space directions, three extra times, $\Gamma^{x4}{}_{x4x4} = 0$, and $f_0 = \cot z$ does not depend on x_4; equivalently $\partial_4 \ln\sqrt{|g|} = \partial_4 \ln(b_4^{3/2}\cos z) = \frac{3}{2}b_4'/b_4$, Section 6.9), so the second term is

$$-\partial_4 \sum_{\rho} \Gamma^{\rho}{}_{\rho 4} = -3a_4'' - 3\alpha_t',$$

which vanishes for a constant b_4, where $\alpha_t = -a_4'$.

In the fourth term look at the symbols $\Gamma^{\rho}{}_{4\lambda}$ one case at a time. For $\rho = x4$ the symbol is $\partial_\lambda \ln f_4 = 0$ (case (a) for $\lambda = x4$, case (b) otherwise; $f_4 = 1$). For $\lambda = x4$ and $\rho \neq x4$ it is $\Gamma^{\rho}{}_{44} = 0$ (shown above). For ρ, λ and $x4$ all different it is 0 (case (d)). What is left is $\rho = \lambda \neq x4$, case (b): $\Gamma^{\rho}{}_{4\rho} = \partial_4 \ln f_\rho$, which is a_4' for a 3-space direction, α_t for an extra time and $\partial_4 \ln f_0 = 0$ for $x0$. So only the six terms with $\rho = \lambda$ a 3-space direction or an extra time survive, and each is the square of its symbol, because for $\lambda = \rho$ the second factor $\Gamma^{\lambda}{}_{\rho 4} = \Gamma^{\rho}{}_{\rho 4}$ equals the first, $\Gamma^{\rho}{}_{4\rho}$ (the symbols are symmetric in their two lower indices):

$$-\sum_{\rho,\lambda} \Gamma^{\rho}{}_{4\lambda}\Gamma^{\lambda}{}_{\rho 4} = -\big(3a_4'^2 + 3\alpha_t^2\big).$$

So $R_{44} = -3(a_4'^2 + a_4'') - 3(\alpha_t^2 + \alpha_t')$ (the sum of the four terms), and

$$R^{x4}{}_{x4} = g^{44}R_{44} = 3\big(a_4'^2 + a_4''\big) + 3\big(\alpha_t^2 + \alpha_t'\big),$$

with $\alpha_t = -a_4' + b_4'/(2b_4)$ and $\alpha_t' = -a_4'' + b_4''/(2b_4) - b_4'^2/(2b_4^2)$; multiplied out, $R^{x4}{}_{x4} = 6a_4'^2 - 3a_4'b_4'/b_4 + 3b_4''/(2b_4) - 3b_4'^2/(4b_4^2)$, the record's value. At $b_4 = 1$, $\alpha_t = -a_4'$ and $\alpha_t' = -a_4''$, so $R^{x4}{}_{x4} = 3a_4'^2 + 3a_4'' + 3a_4'^2 - 3a_4'' = 6a_4'^2$. The 3-space directions and the extra times enter with opposite rates $\pm a_4'$, but each enters squared, so here they add instead of cancelling.

All Ricci components. Chapter 3 computed all components by hand, from the curvatures of the 28 coordinate planes, in Section 3.25. With b_4 there are ten nonzero mixed components (record `metric-b4.json`, key `ricciMixed`): the eight on the diagonal,

$$R^{x0}{}_{x0} = -6H^2, \quad R^{x_i}{}_{x_i} = a_4'' - 6H^2 + \frac{3a_4'b_4'}{2b_4}, \quad R^{x_t}{}_{x_t} = -a_4'' - 6H^2 - \frac{3a_4'b_4'}{2b_4} + \frac{b_4''}{2b_4} + \frac{b_4'^2}{4b_4^2},$$

and $R^{x4}{}_{x4}$ above, and the two off it, $R^{x4}{}_{x0} = \frac{3}{2}H\cot z\, b_4'/b_4$ and $R^{x0}{}_{x4} = -\frac{3}{2}H\tan z\, b_4'/b_4$, which vanish for a constant b_4. The Ricci scalar is $R = 6a_4'^2 - 3a_4'b_4'/b_4 + 3b_4''/b_4 - 42H^2$. At $b_4 = 1$ these are the values of the record `field-theory.json`,

$$R^{x0}{}_{x0} = -6H^2, \qquad R^{x_i}{}_{x_i} = a_4'' - 6H^2, \qquad R^{x4}{}_{x4} = 6a_4'^2, \qquad R^{x_t}{}_{x_t} = -a_4'' - 6H^2,$$

and $R = -6H^2 + 3(a_4'' - 6H^2) + 6a_4'^2 + 3(-a_4'' - 6H^2) = 6(a_4'^2 - 7H^2)$ (add the eight components; the a_4'' terms cancel). The component $R^{x4}{}_{x4} = 6a_4'^2$ is curvature made entirely by the inflation of 3-space and the deflation of the extra times, **although $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)}$ does not contain a_4 at all**: the contraction is blind to the deflation, the metric is not. For every b_4 the contraction contains b_4 but still no a_4 (Section 6.8).

The curvature of the spinor connection. The commutator of two covariant derivatives of a spinor, line by line:

$$D_\mu D_\nu\Psi = \partial_\mu(\partial_\nu\Psi + \Omega_\nu\Psi) + \Omega_\mu(\partial_\nu\Psi + \Omega_\nu\Psi) = \partial_\mu\partial_\nu\Psi + (\partial_\mu\Omega_\nu)\Psi + \Omega_\nu\partial_\mu\Psi + \Omega_\mu\partial_\nu\Psi + \Omega_\mu\Omega_\nu\Psi$$

(the definition twice; the product rule). Subtract the same with μ and ν exchanged: $\partial_\mu\partial_\nu\Psi$ and the two middle terms are symmetric and cancel, and

$$(D_\mu D_\nu - D_\nu D_\mu)\Psi = F_{\mu\nu}\Psi, \qquad F_{\mu\nu} = \partial_\mu\Omega_\nu - \partial_\nu\Omega_\mu + [\Omega_\mu, \Omega_\nu].$$

Theorem (quoted, and checked exactly for this metric). $F_{\mu\nu} = \frac{1}{2}\sum_{a,b} R_{ab\mu\nu}S^{ab}$, where $R_{ab\mu\nu}$ is the Riemann tensor with its first two indices turned into frame indices (for the diagonal vielbein $R_{ab\mu\nu} = \eta_{aa}f_a R^a{}_{b\mu\nu}/f_b$). The general proof is a standard but long computation that this book does not reproduce; for the author's metric the identity is PROVED by exact computation in all 28 coordinate planes (`wolfram-field-theory-b4.json`, check `spin_curvature_equals_Riemann`, with b_4; at $b_4 = 1$ `python-field-theory.json`, check `spinor_curvature_equals_riemann`, and `wolfram-field-theory.json`, check `spin_curvature_equals_Riemann`; Notebook 06b, In [15]). The spinor curvature is the Riemann curvature acting on spinors.

It cannot be removed by a change of frame. By Section 6.15, $D'_\mu(R\Psi) = R\,D_\mu\Psi$ for every spinor. Apply it twice, the second time to the spinor $D_\nu\Psi$: $D'_\mu D'_\nu(R\Psi) = D'_\mu(R\,D_\nu\Psi) = R\,D_\mu D_\nu\Psi$. Subtracting the same with μ and ν exchanged gives $F'_{\mu\nu}R\Psi = R\,F_{\mu\nu}\Psi$ for every Ψ, so

$$F'_{\mu\nu} = R\,F_{\mu\nu}\,R^{-1}.$$

An invertible R can change the entries of $F_{\mu\nu}$ but cannot make a nonzero matrix zero. If some frame had $\Omega'_\mu = 0$ for all μ, its $F'_{\mu\nu}$ would vanish, hence $F_{\mu\nu}$ in every frame, hence the Riemann tensor, which contradicts $R^{x0}{}_{x0} = -6H^2$. **No frame makes the spin connection vanish.** In the diagonal vielbein 27 of the 28 planes have $F_{\mu\nu} \neq 0$ at the sample point; the plane $(x0, x4)$ has

$F_{x0\,x4} = 0$ exactly, for every b_4, because $\Omega_{x0} = \Omega_{x4} = 0$ make every term of its formula vanish (Notebook 06b, In [16], and figure 5). In the boosted frame with $\beta = 6H$, where the contraction vanished for a constant b_4, $F'_{x0\,x1} = RF_{x0\,x1}R^{-1}$ is not zero (In [15]).

statement	**status**	**where it is verified**

6.18 Changing the field variable: the rescaling $\Psi = \sin^{-1/2}(z)\, b_4^{-3/4}\, \chi$

A frame change is one way to remove the term $\gamma^\mu\Omega_\mu$; a change of the field variable is another. Keep the diagonal vielbein, and write the field as a known function times a new field,

$$\Psi = w\,\chi, \qquad w = \sin^{-1/2}(z)\,b_4^{-3/4}.$$

On the backgrounds $b_4 = 1$ the weight is $w = \sin^{-1/2} z$, the weight of the Revision record.

The derivation. By the product rule, $\partial_\mu(w\chi) = (\partial_\mu w)\chi + w\,\partial_\mu\chi$, so

$$\sum_\mu \gamma^\mu D_\mu \Psi = w \sum_\mu \gamma^\mu \partial_\mu \chi + \Big(\sum_\mu \gamma^\mu \partial_\mu w + w \sum_\mu \gamma^\mu \Omega_\mu\Big)\chi$$

(w is a number at each point and commutes with every matrix). Only x_0 and x_4 appear in w, with $\gamma^{x0} = \tan z\,\gamma^{(x0)}$ and $\gamma^{x4} = \gamma^{(x4)}$, and $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ (Section 6.8), so the bracket is

$$\big(\tan z\,\partial_0 w + 3H\,w\big)\gamma^{(x0)} + \Big(\partial_4 w + \frac{3}{4}\,\frac{b_4'}{b_4}\,w\Big)\gamma^{(x4)}.$$

Now

$$\partial_0 \sin^{-1/2} z = -\tfrac{1}{2}\sin^{-3/2} z \cdot \cos z \cdot 6H = -3H\cos z\,\sin^{-3/2} z$$

(the power rule and the chain rule), and

$$\tan z\,\partial_0 w = \frac{\sin z}{\cos z}\big(-3H\cos z\,\sin^{-3/2} z\big)b_4^{-3/4} = -3H\sin^{-1/2}(z)\,b_4^{-3/4} = -3H\,w$$

(cancel $\cos z$; $\sin z \cdot \sin^{-3/2} z = \sin^{-1/2} z$). In the same way $\partial_4 b_4^{-3/4} = -\frac{3}{4}b_4^{-7/4}b_4'$ (the power rule and the chain rule) gives $\partial_4 w = -\frac{3}{4}(b_4'/b_4)\,w$. Both brackets are zero, $(-3Hw + 3Hw)\gamma^{(x0)} + (-\frac{3}{4}\frac{b_4'}{b_4}w + \frac{3}{4}\frac{b_4'}{b_4}w)\gamma^{(x4)} = 0$:

$$\sum_\mu \gamma^\mu D_\mu(w\chi) = w\sum_\mu \gamma^\mu \partial_\mu \chi.$$

The rescaled field equation. The bilinear is $S[\Psi] = \Psi^\dagger C \Psi$; w is real and positive, so $S[w\chi] = w^2\chi^\dagger C\chi = S[\chi]/(b_4^{3/2}\sin z)$. For the potential $U = \frac{\lambda}{2}S^2$, $U'(S) = \lambda S$, and the field equation $\sum_\mu \gamma^\mu D_\mu\Psi = (m + \lambda S[\Psi])\Psi$ becomes, after division by w,

$$\sum_\mu \gamma^\mu \partial_\mu \chi = \Big(m + \frac{\lambda\,S[\chi]}{b_4^{3/2}\sin z}\Big)\chi.$$

For $U = 0$ ($\lambda = 0$) the term $\gamma^\mu\Omega_\mu$ is removed completely. For $U \neq 0$ it reappears in another form: as the coupling $\lambda S[\chi]/(b_4^{3/2}\sin z)$, which depends on the hidden coordinate (and, through b_4, on the time). What remains of gravity in the equation of χ are the vielbein factors $1/f_a$ in front of every derivative.

statement	status	where it is verified
$\sum_\mu \gamma^\mu D_\mu(w\chi) = w\sum_\mu \gamma^\mu \partial_\mu \chi$ for $w = \sin^{-1/2}(z)\, b_4^{-3/4}$ and any 16 functions χ	PROVED	Notebook 06b, In [17]; at $b_4 = 1$ ($w = \sin^{-1/2} z$): `python-scope.json` and `wolfram-scope.json`, check `rescaling_remove s_the_connection_term`
$S[w\chi] = S[\chi]/(b_4^{3/2}\sin z)$; the rescaled equation with $U = \frac{\lambda}{2}S^2$	PROVED	Notebook 06b, In [17]; at $b_4 = 1$: both scope reports, check `rescaled_equatio n_quadratic_potential`

6.19 Example: Notebook 06b

Notebook 06b checks Sections 6.15 to 6.18 with exact algebra, for arbitrary functions $a_4(x_4)$ and $b_4(x_4)$. It rebuilds the tools of Notebook 06a (so that it runs on its own), recomputes the diagonal vielbein and its contraction $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ as a control, builds the boost matrix and checks that it keeps η, and draws the boosted frame on its hyperbolas. It then computes the canonical spin connection of the boosted frame with a symbolic rate β and starting value b_0, checks the vielbein postulate, the formula $\frac{6H-\beta}{2}(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}) + \frac{3}{4}\frac{b_4'}{b_4}(\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)})$ and its vanishing at $\beta = 6H$ for a constant b_4, and explains it with the explicit spinor boost R. It computes the Riemann tensor, the Ricci tensor (with its two components off the diagonal) and the spinor curvature in all 28 planes, and finally the rescaling. It compares every result that the Revision records also contain with the records (the record of the metric with b_4 where it has the result, and the two scope reports of $b_4 = 1$), draws six figures, needs no Rust, runs in about two minutes and ends with the line ALL 26 CHECKS PASSED (notebook 06b).

6.20 How to run Notebook 06b

Step 1. What this notebook does and what it needs.

Notebook 06b (What depends on the frame: boosts, spin covariance, curvature, rescaling) is the file `Revision/textbook/notebooks/06b_frame_dependence.ipynb` of the repository Dirac_claude. For the author's metric with the functions a4(x4) and b4(x4) it boosts the diagonal vielbein in the (x4, x0) plane with a time-dependent rapidity and computes exactly, with sympy, the new spin connection and the new contraction gamma^mu Omega_mu = ((6 H - beta)/2)(cosh b gamma^(x0) - sinh b gamma^(x4)) + (3/4)(b4'/b4)(cosh b gamma^(x4) - sinh b gamma^(x0)), which vanishes identically for the rapidity rate beta = 6 H when b4 is constant; it verifies the local spin covariance of the connection with an explicit spinor boost, computes the Riemann and Ricci tensors and the curvature of the spinor connection, which no frame can remove, shows that the rescaling Psi = sin^(-1/2)(z) b4^(-3/4) chi removes the whole term gamma^mu Omega_mu, checks every result against the Revision records and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It

does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 06b_frame_dependence.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06b_frame_dependence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 06b_frame_dependence.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/06b.captions.json`
- `Revision/textbook/figures/06b_1_boost_hyperbolas.png`
- `Revision/textbook/figures/06b_2_boosted_contraction.png`
- `Revision/textbook/figures/06b_3_boosted_connection_heat_maps.png`
- `Revision/textbook/figures/06b_4_ricci_components.png`
- `Revision/textbook/figures/06b_5_spinor_curvature_norms.png`
- `Revision/textbook/figures/06b_6_rescaling.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 26 CHECKS PASSED (notebook 06b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/06b_frame_dependence.ipynb` inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 06b_frame_dependence.ipynb
python -m nbconvert --execute --inplace 06b_frame_dependence.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook reads Revision records from the repository; open it inside the folder Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single downloaded notebook file is not enough).
- a cell runs for several minutes: the exact algebra of sympy with hyperbolic functions and two unknown functions is slow on old computers; the whole notebook needs about two minutes on a 2024 laptop, and up to about four minutes while other programs use the processor. Wait, or close the other programs.

6.21 Notebook 06b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/06b_frame_dependence.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The previous notebook of this chapter (06a) found $\gamma^\mu\Omega_\mu =
3H\gamma^{(x0)} + \frac34(b_4'/b_4)\gamma^{(x4)}$ for the author's metric in the
DIAGONAL vielbein ($3H\gamma^{(x0)}$ when $b_4$ is constant). A vielbein is a
choice: at every point any other set of eight perpendicular unit directions
describes the same metric. This notebook asks which results depend on that choice
and which do not. It

- builds a second vielbein of the same metric, the diagonal one **boosted** in the
  plane of the time $x4$ and the hidden direction $x0$ by a rapidity
  $b = \beta x_4 + b_0$ that grows with the time;
- computes its canonical spin connection and finds exactly
  $\gamma'^\mu\Omega'_\mu = \frac{6H - \beta}{2}\big(\cosh b\,\gamma^{(x0)} -
  \sinh b\,\gamma^{(x4)}\big) + \frac34\frac{b_4'}{b_4}\big(\cosh b\,
  \gamma^{(x4)} - \sinh b\,\gamma^{(x0)}\big)$, which VANISHES for $\beta = 6H$
  when $b_4$ is constant, although $\Omega'_\mu$ itself does not vanish;
- explains the formula with the **local spin covariance** of the connection,
  using the explicit spinor boost $R = \cosh\frac{b}{2} -
  \sinh\frac{b}{2}\,\gamma^{(x4)}\gamma^{(x0)}$;
- computes the Riemann and Ricci tensors and the curvature
  $F_{\mu\nu}$ of the spinor connection, checks $F_{\mu\nu} =
  \frac12 R_{ab\mu\nu}S^{ab}$ in all 28 coordinate planes, and shows that this
  curvature, which no choice of frame can remove, is nonzero for every $H > 0$;
- shows that the rescaled field $\chi = \sin^{1/2}(z)\,b_4^{3/4}\,\Psi$ obeys an
  equation without the term $\gamma^\mu\Omega_\mu$;
- checks every result against the Revision records (with $b_4$ where the record has
  it, and at $b_4 = 1$) and draws six teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 06b (What depends on the frame: boosts, spin covariance, curvature, rescaling)
is the file ‘Revision/textbook/notebooks/06b_frame_dependence.ipynb‘ of the repository
Dirac_claude. For the author's metric with the functions a4(x4) and b4(x4) it boosts the
diagonal vielbein in the (x4, x0) plane with a time-dependent rapidity and computes
exactly, with sympy, the new spin connection and the new contraction gammaˆmu Omega_mu =
((6 H - beta)/2)(cosh b gammaˆ(x0) - sinh b gammaˆ(x4)) + (3/4)(b4'/b4)(cosh b gammaˆ(x4)
- sinh b gammaˆ(x0)), which vanishes identically for the rapidity rate beta = 6 H when b4
is constant; it verifies the local spin covariance of the connection with an explicit
spinor boost, computes the Riemann and Ricci tensors and the curvature of the spinor
connection, which no frame can remove, shows that the rescaling Psi = sinˆ(-1/2)(z)
b4ˆ(-3/4) chi removes the whole term gammaˆmu Omega_mu, checks every result against the
Revision records and draws six teaching plots. It needs a computer with Windows 11, macOS
or Linux, an internet connection for the installation, the program Git, and Python 3.12
or newer (the notebooks were built with Python 3.14.5) with these packages at exactly
these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the
program that shows and runs notebooks. It does not need Rust.
```

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home

folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 06b_frame_dependence.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06b_frame_dependence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 06b_frame_dependence.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/06b.captions.json‘
- ‘Revision/textbook/figures/06b_1_boost_hyperbolas.png‘

- ‘Revision/textbook/figures/06b_2_boosted_contraction.png‘
- ‘Revision/textbook/figures/06b_3_boosted_connection_heat_maps.png‘
- ‘Revision/textbook/figures/06b_4_ricci_components.png‘
- ‘Revision/textbook/figures/06b_5_spinor_curvature_norms.png‘
- ‘Revision/textbook/figures/06b_6_rescaling.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 26 CHECKS PASSED (notebook 06b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/06b_frame_dependence.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
      python -m jupyterlab 06b_frame_dependence.ipynb
      python -m nbconvert --execute --inplace 06b_frame_dependence.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook
  reads Revision records from the repository; open it inside the folder
  Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single
  downloaded notebook file is not enough).
- a cell runs for several minutes: the exact algebra of sympy with hyperbolic functions
  and two unknown functions is slow on old computers; the whole notebook needs about two
  minutes on a 2024 laptop, and up to about four minutes while other programs use the
  processor. Wait, or close the other programs.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 06b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 06b (What depends on the frame: boosts, spin covariance, curvature, rescaling)
# is the file Revision/textbook/notebooks/06b_frame_dependence.ipynb of the repository
# Dirac_claude. For the author's metric with the functions a4(x4) and b4(x4) it boosts
# the diagonal vielbein in the (x4, x0) plane with a time-dependent rapidity and computes
# exactly, with sympy, the new spin connection and the new contraction gamma^mu Omega_mu
# = ((6 H - beta)/2)(cosh b gamma^(x0) - sinh b gamma^(x4)) + (3/4)(b4'/b4)(cosh b
# gamma^(x4) - sinh b gamma^(x0)), which vanishes identically for the rapidity rate beta
# = 6 H when b4 is constant; it verifies the local spin covariance of the connection with
# an explicit spinor boost, computes the Riemann and Ricci tensors and the curvature of
# the spinor connection, which no frame can remove, shows that the rescaling Psi =
# sin^(-1/2)(z) b4^(-3/4) chi removes the whole term gamma^mu Omega_mu, checks every
# result against the Revision records and draws six teaching plots. It needs a computer
# with Windows 11, macOS or Linux, an internet connection for the installation, the
# program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
```

```
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
```

```
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
```

```
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 06b_frame_dependence.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 06b_frame_dependence.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 06b_frame_dependence.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/06b.captions.json
# - Revision/textbook/figures/06b_1_boost_hyperbolas.png
# - Revision/textbook/figures/06b_2_boosted_contraction.png
# - Revision/textbook/figures/06b_3_boosted_connection_heat_maps.png
# - Revision/textbook/figures/06b_4_ricci_components.png
# - Revision/textbook/figures/06b_5_spinor_curvature_norms.png
# - Revision/textbook/figures/06b_6_rescaling.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
```

```
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 26 CHECKS PASSED (notebook 06b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/06b_frame_dependence.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 06b_frame_dependence.ipynb
#     python -m nbconvert --execute --inplace 06b_frame_dependence.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or for a report: the notebook
#   reads Revision records from the repository; open it inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a
#   single downloaded notebook file is not enough).
```

```
# - a cell runs for several minutes: the exact algebra of sympy with hyperbolic functions
#   and two unknown functions is slow on old computers; the whole notebook needs about
#   two minutes on a 2024 laptop, and up to about four minutes while other programs use
#   the processor. Wait, or close the other programs.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "06b"  # this notebook: chapter 06, example b

## 3. The words used in this notebook

- **Vielbein** $e^a{}_\mu$: eight perpendicular unit directions at every point
  (frame index $a$, coordinate index $\mu$), with $g_{\mu\nu} = \sum_a \eta_{aa}
  e^a{}_\mu e^a{}_\nu$; $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the
  order $x0, \dots, x7$. In Python lists the directions have the positions 0 to 7
  in the same order, so `x[0]` is $x0$ and `x[4]` is $x4$.
- **Frame rotation** (local Lorentz transformation): a new vielbein
  $e'^a{}_\mu = \sum_b \Lambda^a{}_b(x)\,e^b{}_\mu$ with a matrix $\Lambda(x)$
  that keeps $\eta$: $\Lambda^T\eta\Lambda = \eta$. It describes the same metric.
- **Boost**: a frame rotation that mixes one space-like and one time-like
  direction. In the plane of the time $x4$ (time-like) and the hidden direction
  $x0$ (space-like) it is $e'^{(x4)} = \cosh b\, e^{(x4)} + \sinh b\, e^{(x0)}$,
  $e'^{(x0)} = \sinh b\, e^{(x4)} + \cosh b\, e^{(x0)}$.
- **Rapidity** $b$: the "angle" of a boost. **Hyperbolic functions**:
  $\cosh b = (e^b + e^{-b})/2$ and $\sinh b = (e^b - e^{-b})/2$; they satisfy
  $\cosh^2 b - \sinh^2 b = 1$, just as $\cos^2 + \sin^2 = 1$ for rotations.
- **Spin connection** $\omega_{\mu ab}$, **spinor connection** $\Omega_\mu =
  \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$ with $S^{ab} = \frac14[\gamma^a,
  \gamma^b]$, **curved gammas** $\gamma^\mu = \sum_a e_a{}^\mu\gamma^a$,
  **covariant derivative** $D_\mu = \partial_\mu + \Omega_\mu$: as in Notebook
  06a. A prime marks the quantities of the boosted vielbein.
- **Spinor boost** $R(x)$: a 16 x 16 matrix that turns spinors when the frame is
  boosted; it **covers** $\Lambda$ when $R^{-1}\gamma^a R = \sum_b \Lambda^a{}_b
  \gamma^b$ for every $a$.
- **Riemann tensor** $R^\rho{}_{\sigma\mu\nu}$: the measure of curvature, built
  from the Christoffel symbols and their derivatives; it is zero everywhere only
  for a flat space. **Ricci tensor** $R_{\sigma\nu} = \sum_\rho
```

```
  R^\rho{}_{\sigma\rho\nu}$, mixed form $R^\mu{}_\nu = \sum_\sigma g^{\mu\sigma}
  R_{\sigma\nu}$, **Ricci scalar** $R = \sum_\mu R^\mu{}_\mu$.
- **Curvature of the spinor connection** $F_{\mu\nu} = \partial_\mu\Omega_\nu -
  \partial_\nu\Omega_\mu + [\Omega_\mu, \Omega_\nu]$: the 16 x 16 matrix with
  $D_\mu D_\nu\Psi - D_\nu D_\mu\Psi = F_{\mu\nu}\Psi$.
- **Frame-dependent**: a quantity whose value changes when the vielbein is
  changed (such as $\gamma^\mu\Omega_\mu$). **Frame-independent**: a statement
  that holds in every vielbein (such as "$F_{\mu\nu}$ is not zero").
- **Rescaling**: writing the field as a known function times a new field,
  $\Psi = w(x)\,\chi$, and deriving the equation that $\chi$ obeys.
- **Exact** check: sympy proves that an expression is zero for ALL values of its
  symbols. **Heat map**: a picture of a matrix, red positive, blue negative,
  white zero.
```

```
## 4. The physical and mathematical situation

The metric is the author's, with $z = 6Hx_0$ in $(0, \pi/2)$, $H > 0$ and two
arbitrary functions $a_4(x_4)$ and $b_4(x_4) > 0$:

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}\sin^{1/3}z\ (\times 3),\ -1,\
-e^{-2a_4}b_4\sin^{1/3}z\ (\times 3)\big).$$

The diagonal vielbein has the factors $f = (\cot z,\ e^{a_4}s\ (\times 3),\ 1,\
e^{-a_4}b_4^{1/2}s\ (\times 3))$, $s = \sin^{1/6}z$. On the backgrounds of this
book $b_4 = 1$. The canonical spin connection of ANY vielbein $e$ is
$\omega_\mu{}^a{}_b = \sum_\nu e^a{}_\nu (\partial_\mu e_b{}^\nu +
\sum_\lambda\Gamma^\nu{}_{\mu\lambda}e_b{}^\lambda)$.

**The theorem behind this notebook (local spin covariance).** If $e' = \Lambda e$
and the spinor matrix $R(x)$ covers $\Lambda(x)$, then

$$\Omega'_\mu = R\,\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}, \qquad
\gamma'^\mu = R\,\gamma^\mu R^{-1}, \qquad F'_{\mu\nu} = R\,F_{\mu\nu}R^{-1}.$$

Multiplying the first two and summing over $\mu$ gives

$$\gamma'^\mu\Omega'_\mu = R\,(\gamma^\mu\Omega_\mu)\,R^{-1} -
\sum_\mu\gamma'^\mu(\partial_\mu R)R^{-1}.$$

The second term can cancel the first: the contraction $\gamma^\mu\Omega_\mu$ is
frame-dependent. The curvature only gets turned by $R$, so if $F_{\mu\nu} \ne 0$
in one frame, it is nonzero in every frame: no frame removes the spinor
connection itself.

**Status.** Every statement checked below is PROVED exactly (sympy, symbolic $H$,
$a_4$, $b_4$, $\beta$, $b_0$). The scope records (`python-scope.json`,
`wolfram-scope.json`) state these results for the metric at $b_4 = 1$; the notebook
reproduces them there and computes the general case itself. This is the record's
own correction of the non-triviality statement: the value of
$\gamma^\mu\Omega_\mu$ belongs to the diagonal vielbein; what is
frame-independent is the curvature.
```

Text cell:

```
## 5. The tools: sympy, the author's gammas and the general formulas

This notebook repeats the tools of Notebook 06a, so that it runs on its own. The
next cell reads the author's gammas and the matrix $C$ from
`Revision/algebra/gammas.json`, checks the 64 Clifford relations, builds the 28
matrices $S^{ab}$, and defines the exact zero test `is_zero` (first a fast route
through exponential functions, then sympy's `simplify`; it never calls a nonzero
expression zero) and `record_passed`, which reads a Revision report and tells
whether a check is recorded as passed.

The first lines of the next cell change one setting of Jupyter: printed text is
sent to the screen when a cell has finished (or just before a figure is shown),
not every 0.2 seconds. This changes no result; it makes the printed text arrive in
the same pieces in every run, which the book's checking tool needs.
```

In [2]:

```
import sys  # the Python system module (here: the stream of printed text)

# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
import numpy as np  # decimal numbers for the plots
import sympy as sp  # exact algebra and calculus with symbols

## 8. The boosted vielbein and its canonical spin connection

Now the rapidity depends on the time: $b = \beta x_4 + b_0$ with two constants
$\beta$ (the rate) and $b_0$ (the starting value). The boosted vielbein is the
matrix product $e' = \Lambda(b)\,e$. The next cell checks that it describes the
author's metric (all 64 entries of $e'^T\eta e'$), computes its canonical spin
connection, and checks the vielbein postulate (512 equations) and the
antisymmetry $\omega'_{\mu ab} = -\omega'_{\mu ba}$, for every $b_4$. At $b_4 = 1$
these are the record's checks `boosted_frame_reproduces_metric` and
`boosted_frame_canonical_connection`.
```

In [7]:

```
beta, b0 = sp.symbols("beta b0", real=True)  # the rate and the start of the rapidity
b = beta * x4 + b0  # the rapidity grows with the time
```

## 9. The contraction in the boosted vielbein

The next cell computes $\gamma'^\mu\Omega'_\mu$ (summed over $\mu$) and compares it,
exactly, for symbolic $a_4$, $b_4$, $H$, $\beta$ and $b_0$, with

$$\gamma'^\mu\Omega'_\mu = \frac{6H - \beta}{2}\,v + \frac34\,\frac{b_4'}{b_4}\,
w, \qquad v = \cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)},\quad
w = \cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)} .$$

At $b_4 = 1$ the second term is absent, and the formula is the record's. At $b = 0$
(no boost) it gives back $3H\gamma^{(x0)} + \frac34(b_4'/b_4)\gamma^{(x4)}$. The
coefficient $(6H - \beta)/2$ already shows the surprise: for the rate
$\beta = 6H$ the first term is zero.
```

## 10. The rate $\beta = 6H$: the contraction vanishes for constant $b_4$

The next cell puts $\beta = 6H$ into the boosted spin connection (substituting
after the computation is allowed, because the computation was done for every
$\beta$). It checks that $\gamma'^\mu\Omega'_\mu = \frac34(b_4'/b_4)\,w$ is all that
remains, so that the contraction is zero identically, for every $H > 0$ and every
```

```
$a_4$, exactly when $b_4$ is constant (the record's statement at $b_4 = 1$); and
that $\Omega'_\mu$ is nonzero for $\mu = x1, \dots, x7$ and zero only for
$\mu = x0$. So for a constant $b_4$ the field equation $\gamma'^\mu D'_\mu\Psi' =
(m + U')\Psi'$ in this vielbein has no term $\gamma'^\mu\Omega'_\mu\Psi'$ at all,
although the spinor connection is everywhere. (The matrices $v$ and $w$ are
independent, so no rate $\beta$ removes the term $\frac34(b_4'/b_4)w$ of a changing
$b_4$; the rescaling of Section 14 removes the whole term.)

## 11. Why: the local spin covariance, with an explicit spinor boost

The next cell takes the 16 x 16 matrix $X = \gamma^{(x4)}\gamma^{(x0)}$. Since
$X^2 = -\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)}\gamma^{(x0)} = -(-1)(+1) = 1$,
the spinor boost $R = \cosh\frac b2 - \sinh\frac b2\,X$ has the inverse
$R^{-1} = \cosh\frac b2 + \sinh\frac b2\,X$ (multiply them: $\cosh^2 -
\sinh^2 X^2 = 1$). The cell checks, exactly:

1. $R^{-1}\gamma^a R = \sum_c\Lambda^a{}_c\gamma^c$ for all eight $a$: $R$
   covers the boost $\Lambda(b)$;
2. $\gamma'^\mu = R\,\gamma^\mu R^{-1}$ and $\Omega'_\mu = R\,\Omega_\mu R^{-1} -
   (\partial_\mu R)R^{-1}$ for all eight $\mu$ (the covariance theorem);
3. the two pieces of the formula of Section 9: $R\,\gamma^{(x0)}R^{-1} = v$ and
   $R\,\gamma^{(x4)}R^{-1} = w$, so that the turned contraction is
   $R(3H\gamma^{(x0)} + \frac34\frac{b_4'}{b_4}\gamma^{(x4)})R^{-1} = 3Hv +
   \frac34\frac{b_4'}{b_4}w$, and the extra term $\sum_\mu\gamma'^\mu(\partial_\mu
   R)R^{-1} = \frac{\beta}{2}\,v$ (only $\mu = x4$ contributes, because $R$ depends
   on $x_4$ only). Their difference is the formula of Section 9.

## 12. The curvature: the Riemann and Ricci tensors

The next cell computes the Riemann tensor of the author's metric from the
Christoffel symbols with the convention $R^\rho{}_{\sigma\mu\nu} =
\partial_\mu\Gamma^\rho{}_{\nu\sigma} - \partial_\nu\Gamma^\rho{}_{\mu\sigma} +
\sum_\lambda(\Gamma^\rho{}_{\mu\lambda}\Gamma^\lambda{}_{\nu\sigma} -
\Gamma^\rho{}_{\nu\lambda}\Gamma^\lambda{}_{\mu\sigma})$ (it keeps the components
with $\mu < \nu$; the others follow from the antisymmetry in $\mu, \nu$), then the
mixed Ricci components $R^\mu{}_\nu$ and the Ricci scalar. It compares them with
the record of the metric with $b_4$ (‘ricciMixed‘ and ‘ricciScalar‘ of
‘Revision/metric_b4/results/metric-b4.json‘, which also lists the two components
off the diagonal, $R^{x4}{}_{x0}$ and $R^{x0}{}_{x4}$, proportional to $b_4'$) and,
at $b_4 = 1$, with the record ‘field-theory.json‘ (‘ricci_mixed_diagonal‘,
‘ricci_scalar‘), whose values are

$$R^{x0}{}_{x0} = -6H^2,\quad R^{x1}{}_{x1} = R^{x2}{}_{x2} = R^{x3}{}_{x3} =
a_4'' - 6H^2,\quad R^{x4}{}_{x4} = 6a_4'^2,\quad R^{x5}{}_{x5} = R^{x6}{}_{x6} =
R^{x7}{}_{x7} = -a_4'' - 6H^2,$$

and $R = 6(a_4'^2 - 7H^2)$. The component $R^{x0}{}_{x0} = -6H^2$ holds for every
$b_4$ and is negative for every $H > 0$ and every $a_4$: the metric is never flat.
At $b_4 = 1$ the component $R^{x4}{}_{x4} = 6a_4'^2$ shows that the deflation makes
curvature, although $\gamma^\mu\Omega_\mu$ does not contain $a_4$ at all.

## 13. The curvature of the spinor connection

The next cell computes, in the diagonal vielbein, the 28 matrices $F_{\mu\nu}$
($\mu < \nu$) and checks the theorem $F_{\mu\nu} = \frac12\sum_{a,b}
R_{ab\mu\nu}S^{ab}$, where $R_{ab\mu\nu} = \eta_{aa}\,f_a\,R^a{}_{b\mu\nu}/f_b$
is the Riemann tensor with two frame indices (for the diagonal vielbein), for every
$b_4$. Then it computes $F'_{x0\,x1}$ in the boosted vielbein with $\beta = 6H$
(where the contraction vanished for a constant $b_4$) and checks that it is
$R\,F_{x0\,x1}R^{-1}$ and is not zero: the spinor connection is still there and
curved.
```

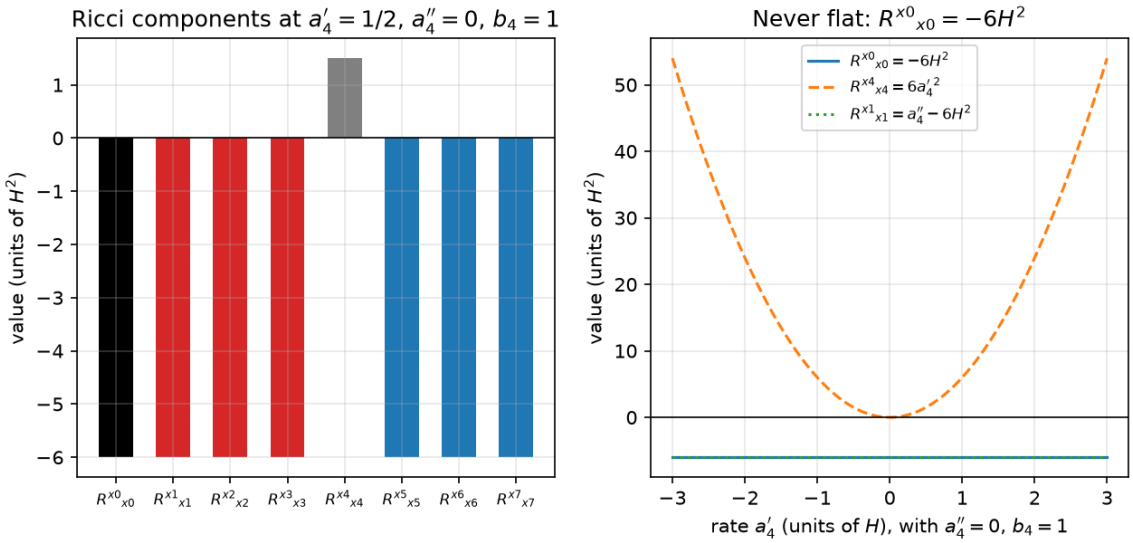

Figure 195: The mixed Ricci components $R^{\mu}{}_{\mu}$ of the author's metric on the background $b_4 = 1$, in units of H^2. Left: all eight at $H = 1$, $a_4' = 1/2$, $a_4'' = 0$ (black: hidden direction, red: 3-space, gray: time, blue: extra times). Right: $R^{x0}{}_{x0} = -6H^2$ (solid), $R^{x4}{}_{x4} = 6a_4'^2$ (dashed) and $R^{x1}{}_{x1} = a_4'' - 6H^2$ (dotted) versus the rate a_4' in units of H with $a_4'' = 0$. The hidden component is negative for every history (and every b_4), so the metric is never flat, and the time component is curvature made by the expansion and deflation (the dotted line lies on the solid one because $a_4'' = 0$). ## 14. The rescaling $\Psi = \sin^{-1/2}(z)\,b_4^{-3/4}\,\chi$ removes the term

A frame change is one way to remove $\gamma^\mu\Omega_\mu$; a change of the field
variable is another. Write $\Psi = w_r\,\chi$ with $w_r = \sin^{-1/2}(z)\,
b_4^{-3/4}$. Then $\gamma^\mu D_\mu\Psi = w_r\,\gamma^\mu\partial_\mu\chi +
\big(\gamma^\mu\partial_\mu w_r + w_r\,\gamma^\mu\Omega_\mu\big)\chi$. The weight
depends on $x_0$ and $x_4$, with $\gamma^{x0} = \tan z\,\gamma^{(x0)}$ and
$\gamma^{x4} = \gamma^{(x4)}$, so the bracket is $\big(\tan z\,\partial_{x0}w_r +
3Hw_r\big)\gamma^{(x0)} + \big(\partial_{x4}w_r + \frac34\frac{b_4'}{b_4}w_r\big)
\gamma^{(x4)}$. Now $\partial_{x0}\sin^{-1/2}z = -\frac12\sin^{-3/2}z\cdot 6H\cos z$
gives $\tan z\,\partial_{x0}w_r = -3Hw_r$, and $\partial_{x4}b_4^{-3/4} =
-\frac34 b_4^{-7/4}b_4'$ gives $\partial_{x4}w_r = -\frac34\frac{b_4'}{b_4}w_r$:
the bracket is zero. At $b_4 = 1$ the weight is the record's $\sin^{-1/2}z$. The
next cell checks this as a matrix identity and, for safety, on 16 completely
general functions $\chi_1, \dots, \chi_{16}$ of all eight coordinates. It also
checks the record's remark about the potential $U = \frac{\lambda}{2}S^2$: since
$w_r$ is real, $S[\Psi] = \Psi^\dagger C\Psi = w_r^2\,S[\chi] =
S[\chi]/(b_4^{3/2}\sin z)$, so the rescaled equation is $\gamma^\mu
\partial_\mu\chi = \big(m + \lambda S[\chi]/(b_4^{3/2}\sin z)\big)\,\chi$: for
$U = 0$ the term is removed completely; for $U \ne 0$ it becomes a coupling that
depends on $x_0$ (and on $x_4$ through $b_4$).
```

(Notebook 06b, figure 6.)

```
## 15. The last checks

The last cell checks that every check of the Revision reports that states a result
reproduced in this notebook is recorded there as passed (the sympy scope checker
‘python-scope.json‘, the WolframScript scope checker ‘wolfram-scope.json‘, which
shares no code with it, and the curvature checks of the field-theory reports, with
$b_4$ and at $b_4 = 1$), that all six figure files exist in the folder
Revision/textbook/figures, and prints the number of checks that passed.
```

In [19]:

```
## 16. What this notebook showed

- A boost of the frame in the $(x4, x0)$ plane with rapidity $b = \beta x_4 + b_0$
  describes the same metric, and its canonical spin connection obeys the vielbein
  postulate. In it $\gamma'^\mu\Omega'_\mu = \frac{6H-\beta}{2}(\cosh b\,
  \gamma^{(x0)} - \sinh b\,\gamma^{(x4)}) + \frac34\frac{b_4'}{b_4}(\cosh b\,
  \gamma^{(x4)} - \sinh b\,\gamma^{(x0)})$ exactly (PROVED; at $b_4 = 1$ it
  reproduces the record). For $\beta = 6H$ and a constant $b_4$ the contraction
  vanishes identically, while $\Omega'_\mu$ is nonzero for $\mu = x1, \dots, x7$.
- The reason is the local spin covariance: with the spinor boost
  $R = \cosh\frac b2 - \sinh\frac b2\,\gamma^{(x4)}\gamma^{(x0)}$, $\Omega'_\mu =
  R\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}$, and the second term contributes
  $-\frac{\beta}{2}(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)})$ (PROVED
  here).
- So the value of $\gamma^\mu\Omega_\mu$ in the diagonal vielbein is
  FRAME-DEPENDENT. What is frame-independent: the metric is curved for every
  $H > 0$ and every $b_4$ ($R^{x0}{}_{x0} = -6H^2$, PROVED; reproduces the
  records), the spinor curvature is $F_{\mu\nu} = \frac12 R_{ab\mu\nu}S^{ab}$ in
  all 28 planes (PROVED; reproduces the record), and it is nonzero in every frame
  because $F' = RFR^{-1}$; therefore no frame makes $\Omega_\mu$ vanish.
- The deflation makes curvature ($R^{x4}{}_{x4} = 6a_4'^2$ at $b_4 = 1$) that the
  contraction $\gamma^\mu\Omega_\mu$ does not see (PROVED; reproduces the record).
- The rescaling $\Psi = \sin^{-1/2}(z)\,b_4^{-3/4}\,\chi$ removes the term
  $\gamma^\mu\Omega_\mu$ from the field equation exactly; with
  $U = \frac\lambda2 S^2$ it becomes the coupling
  $\lambda S[\chi]/(b_4^{3/2}\sin z)$ (PROVED; at $b_4 = 1$ it reproduces the
  record).
- In short, the non-triviality of the field equations holds in the qualified sense
  of the record: the gravitational field enters through the vielbein factors of
  every derivative term and through a spin connection whose curvature cannot be
  removed, but the particular term $\gamma^\mu\Omega_\mu$ is a property of the
  chosen frame and field variables.
```

6.22 Line-by-line walk-through of Notebook 06b

The notebook has 19 code cells, In [1] to In [19]; this section explains every line of every one of them. As in Section 6.14, a line `...` in a quoted figure cell stands for the remaining lines of a long caption, printed in full in Section 6.21.

In [1], the set-up cell. Its comment lines are the run instructions of Section 6.20. Its code is, line for line, the set-up code of Notebook 06a explained at the beginning of Section 6.14, with the single difference

```
NOTEBOOK_ID = "06b"  # this notebook: chapter 06, example b
```

so that the figures are named `06b_<k>_<name>.png` and the captions file is `Revision/textbook/figures/06b.captions.json`. It prints one line, Set-up of notebook 06b complete: repository folder found, helpers defined.

In [2], the tools.

```
import sys  # the Python system module (here: the stream of printed text)

# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
```

The same setting of the output channel as in In [2] of Notebook 06a: inside Jupyter the printed text of a cell is sent in one piece, so that every PASS line arrives together with its "reproduces" line.

```
import numpy as np  # decimal numbers for the plots
import sympy as sp  # exact algebra and calculus with symbols
from sympy.parsing.mathematica import parse_mathematica  # reads Wolfram notation
```

numpy for the plots, sympy for the exact algebra, and sympy's reader of Wolfram notation.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
NAMES = fixture["coordinates"]  # ["x0", ..., "x7"]
ETA = fixture["eta"]  # +1 space-like, -1 time-like
gamma = [sp.Matrix(rows) for rows in fixture["gamma"]]  # gamma[a] = gamma^(xa)
C = sp.Matrix(fixture["C"])  # the author's C (Dirac adjoint Psibar = Psi^dagger C)
I16, Z16 = sp.eye(16), sp.zeros(16, 16)
```

The record `Revision/algebra/gammas.json` is read as in Notebook 06a: the direction names, the signs of η, and the eight gammas as exact matrices. New is `C`, the author's matrix $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$ stored in the same record (Chapter 5); In [17] needs it for the bilinear $S = \Psi^\dagger C \Psi$. `I16, Z16 = ...` gives two names at once (the identity and the zero matrix).

```
check(all(gamma[a] * gamma[b] + gamma[b] * gamma[a]
          == (2 * ETA[a] if a == b else 0) * I16
          for a in range(8) for b in range(8)),
      "the 64 Clifford relations of the author's gammas")
S = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
     for a in range(8)]
```

The 64 Clifford relations (the same test as in Notebook 06a, In [2]) and the 64 generators S^{ab}.

```
def is_zero(expr):
    """True when expr is exactly zero for all values of its symbols."""
    expr = sp.sympify(expr)
    if expr == 0:
        return True
    if sp.cancel(sp.expand(expr.rewrite(sp.exp))) == 0:  # the fast route
        return True
    return sp.simplify(expr) == 0  # the slower general route
```

The exact zero test `is_zero`, explained in Section 6.14 (Notebook 06a, In [3]): first the fast route through exponential functions, then `simplify`; it never calls a nonzero expression zero.

```
def matrix_is_zero(matrix):
    return all(is_zero(entry) for entry in matrix)

def record_passed(path, name):
    """True when the Revision report at path records the check name as passed."""
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in data["checks"]:
        if entry["name"] == name:
            return entry["verdict"].upper() == "PASS"
    raise KeyError(f"{path} has no check {name}")
```

`matrix_is_zero` applies the test to every entry, and `record_passed` reads a Revision report and says whether a check is recorded as passed; both as in Notebook 06a.

```
SCOPE_PY = "Revision/theory/reports/python-scope.json"
SCOPE_WL = "Revision/theory/reports/wolfram-scope.json"
REPORT_PY = "Revision/theory/reports/python-field-theory.json"
REPORT_WL = "Revision/theory/reports/wolfram-field-theory.json"
REPORT_WL_B4 = "Revision/theory/reports/wolfram-field-theory-b4.json"
THEORY_FILE = "Revision/theory/field-theory.json"
METRIC_B4_FILE = "Revision/metric_b4/results/metric-b4.json"
```

The paths of the seven records that this notebook reproduces: the two scope reports, the two field-theory reports and the formula file of $b_4 = 1$, the WolframScript report of the field theory with b_4, and the record `metric-b4.json`. The cell prints one PASS line.

In [3], the four general formulas. They are those of Notebook 06a, In [4], written a little more compactly; Section 6.14 explains them line by line.

```
def christoffel(g, coords):
    """Gam[l][m][n] = (1/2) sum_r g^lr (d_m g_rn + d_n g_rm - d_r g_mn)."""
    n = len(coords)
    g_inv = g.inv()
    Gam = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for l in range(n):
        for m in range(n):
            for k in range(m, n):
                value = sum(g_inv[l, r] * (sp.diff(g[r, k], coords[m])
                                           + sp.diff(g[r, m], coords[k])
                                           - sp.diff(g[m, k], coords[r]))
                            for r in range(n) if g_inv[l, r] != 0) / 2
                Gam[l][m][k] = Gam[l][k][m] = sp.simplify(value)
    return Gam
```

The Christoffel symbols; the one difference from Notebook 06a is that the line `Gam[l][m][k] = Gam[l][k][m] = sp.simplify(value)` stores the simplified symbol in both places at once.

```
def spin_connection(e, Gam, coords, eta):
    """omega[mu][a][b] = eta_aa sum_nu e^a_nu (d_mu e_b^nu + Gam^nu_mu,lam e_b^lam)."""
    n = len(coords)
    E = e.inv()  # E[nu, b] = e_b^nu
    omega = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for mu in range(n):
        for a in range(n):
            for b in range(n):
                mixed = 0
                for nu in range(n):
                    if e[a, nu] == 0:
                        continue
                    mixed += e[a, nu] * (sp.diff(E[nu, b], coords[mu]) + sum(
                        Gam[nu][mu][lam] * E[lam, b] for lam in range(n)))
                omega[mu][a][b] = sp.simplify(eta[a] * mixed)
    return omega
```

The canonical spin connection with the first index lowered. Here it matters that the function accepts ANY vielbein matrix `e`, not only a diagonal one: In [7] gives it the boosted vielbein, which has off-diagonal entries in the rows and columns of $x4$ and $x0$, and then the inverse `E = e.inv()` and the sums over `nu` and `lam` really have several terms.

```
def spinor_connection(omega, S):
    """Omega[mu] = sum_{a<b} omega_{mu ab} S^ab."""
    n = len(omega)
    size = S[0][0].shape[0]
    return [sum((omega[mu][a][b] * S[a][b] for a in range(n)
                 for b in range(a + 1, n) if omega[mu][a][b] != 0),
                sp.zeros(size, size)) for mu in range(n)]
```

The spinor connection $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$, as one list comprehension: for each μ a sum of matrices starting from the zero matrix.

```
def curved_gammas(e, gammas):
    """gamma^mu = sum_a e_a^mu gamma^a."""
    E = e.inv()
    return [sum((E[mu, a] * gammas[a] for a in range(len(gammas))),
                sp.zeros(*gammas[0].shape)) for mu in range(len(gammas))]
```

The curved gammas, and one output line.

```
say("defined: christoffel, spin_connection, spinor_connection, curved_gammas")
```

In [4], the diagonal vielbein again (the control).

```
x = sp.symbols("x0:8", real=True)  # x[0] = x0, ..., x[4] = x4, ..., x[7] = x7
x0, x4 = x[0], x[4]
H = sp.Symbol("H", positive=True)
a4 = sp.Function("a4")(x4)  # any function of the time
b4 = sp.Function("b4", positive=True)(x4)  # any positive function of the time
a4p, b4p = sp.Derivative(a4, x4), sp.Derivative(b4, x4)
z = 6 * H * x0
s = sp.sin(z) ** sp.Rational(1, 6)
f = ([sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
     + [sp.exp(-a4) * sp.sqrt(b4) * s] * 3)  # f_0, ..., f_7
g = sp.diag(*[ETA[a] * f[a] ** 2 for a in range(8)])  # the author's metric
e = sp.diag(*f)  # the diagonal vielbein
```

The symbols, the factors, the author's metric with b_4, the diagonal vielbein and the helper `at_b4_1`, exactly as in Notebook 06a, In [7].

```
Gam = christoffel(g, x)
omega = spin_connection(e, Gam, x, ETA)
Omega = spinor_connection(omega, S)
gup = curved_gammas(e, gamma)
slash = sum((gup[mu] * Omega[mu] for mu in range(8)), Z16)
```

The Christoffel symbols, the spin connection, the spinor connection, the curved gammas and the contraction of the diagonal vielbein.

```
c_b4 = sp.Rational(3, 4) * b4p / b4  # the coefficient (3/4) b4'/b4
check(matrix_is_zero(slash - 3 * H * gamma[0] - c_b4 * gamma[4])
      and matrix_is_zero(at_b4_1(slash) - 3 * H * gamma[0]),
      "control: the diagonal vielbein gives gamma^mu Omega_mu = 3 H gamma^(x0) + "
      "(3/4)(b4'/b4) gamma^(x4), 3 H gamma^(x0) at b4 = 1",
      record=f"{SCOPE_PY}, check rescaling_removes_the_connection_term (b4 = 1)")
```

The control: the same code, with no boost, must give $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ (`c_b4` is $\frac{3}{4}b_4'/b_4$), and $3H\gamma^{(x0)}$ at $b_4 = 1$. The check names the scope report's check `rescaling_removes_the_connection_term`, whose detail records this control value at $b_4 = 1$. The cell prints one PASS line with its record.

In [5], the boost matrix (Section 6.16).

```
def boost(b):
    """The 8 x 8 boost matrix Lambda(b) in the plane of x0 (index 0) and x4 (4)."""
    L = sp.eye(8)
    L[0, 0], L[0, 4], L[4, 0], L[4, 4] = sp.cosh(b), sp.sinh(b), sp.sinh(b), sp.cosh(b)
    return L
```

`boost(b)` returns the 8×8 identity with the four entries of the rows and columns 0 ($x0$) and 4 ($x4$) replaced by $\cosh b$, $\sinh b$, $\sinh b$, $\cosh b$. The four assignments are made in one line (a tuple of four places receives a tuple of four values).

```
b_symbol = sp.Symbol("b", real=True)  # a rapidity
eta_matrix = sp.diag(*ETA)
L_test = boost(b_symbol)
```

A symbolic rapidity `b_symbol`, the matrix η as a diagonal matrix, and the boost with this rapidity.

```
check(matrix_is_zero(L_test.T * eta_matrix * L_test - eta_matrix),
      "Lambda(b)^T eta Lambda(b) = eta for every rapidity b")
check(matrix_is_zero(L_test * boost(-b_symbol) - sp.eye(8)),
      "the inverse of the boost with rapidity b is the boost with -b")
```

Two checks for every rapidity: $\Lambda(b)^T \eta \Lambda(b) - \eta = 0$ (`.T` is the transpose), and $\Lambda(b)\Lambda(-b) = 1$, so the inverse boost is the boost with $-b$. The cell prints two PASS lines.

In [6], figure 1.

```
fig, ax = plt.subplots(figsize=(6.4, 6.0))
rapidity = np.linspace(-1.4, 1.4, 200)
ax.plot(np.cosh(rapidity), np.sinh(rapidity), color="tab:blue", linewidth=1.0,
        label="unit hyperbola of the time direction: $t^2 - y^2 = 1$")
ax.plot(np.sinh(rapidity), np.cosh(rapidity), color="tab:orange", linewidth=1.0,
        label="unit hyperbola of the hidden direction: $y^2 - t^2 = 1$")
ax.plot([0, 2.2], [0, 2.2], ":", color="gray", label="light line $t = y$")
```

One square panel. 200 rapidities from -1.4 to 1.4 trace the two unit hyperbolas: $(\cosh b, \sinh b)$, where $t^2 - y^2 = 1$ (blue), and $(\sinh b, \cosh b)$, where $y^2 - t^2 = 1$ (orange); the dotted diagonal is the **light line** $t = y$.

```
for b_value, alpha in ((0.0, 1.0), (0.5, 0.7), (1.0, 0.45)):
    c_b, s_b = np.cosh(b_value), np.sinh(b_value)
    ax.annotate("", xy=(c_b, s_b), xytext=(0, 0), arrowprops=dict(
        arrowstyle="-|>", color="tab:blue", alpha=alpha, linewidth=1.6))
    ax.annotate("", xy=(s_b, c_b), xytext=(0, 0), arrowprops=dict(
        arrowstyle="-|>", color="tab:orange", alpha=alpha, linewidth=1.6))
    ax.text(c_b + 0.04, s_b - 0.12, f"$b = {b_value:g}$", fontsize=8,
            color="tab:blue")
    ax.text(s_b - 0.30, c_b + 0.06, f"$b = {b_value:g}$", fontsize=8,
            color="tab:orange")
```

For the rapidities $b = 0$, 0.5 and 1 two arrows are drawn from the origin with `annotate` (an annotation with an empty text and an arrow): the boosted time direction to $(\cosh b, \sinh b)$ and the boosted hidden direction to $(\sinh b, \cosh b)$, fainter for larger b (`alpha` is the opacity). `ax.text` writes the value of b next to each arrow tip (`{b_value:g}` writes the number in its shortest form).

```
ax.set_xlim(-0.4, 2.3)
ax.set_ylim(-0.25, 2.3)
ax.set_aspect("equal")
ax.set_xlabel("component along $e^{(x4)}$ (time), $t$")
ax.set_ylabel("component along $e^{(x0)}$ (hidden direction), $y$")
ax.set_title("A boost moves the frame along hyperbolas")
ax.legend(fontsize=8, loc="upper left")
```

The axis ranges, equal units on both axes, the labels and the legend.

```
save_figure(fig, "boost_hyperbolas",
            "A boost of the frame in the plane of the time $x4$ and the hidden "
            ...
            "and tilt symmetrically towards the light line $t = y$ (dotted).")
```

The figure is saved; the cell prints its file name.

What Figure 06b.1 shows. At $b = 0$ the two arrows point along the axes. As b grows, the blue arrow (the time direction) moves along its hyperbola away from the horizontal axis and the orange arrow (the hidden direction) along its hyperbola away from the vertical axis: both tilt symmetrically towards the light line, and both get longer on the paper, while their η-lengths stay -1 and $+1$. They remain perpendicular in the sense of η ($-\cosh b \sinh b + \sinh b \cosh b = 0$). A boost never brings the arrows back, unlike a rotation.

In [7], the boosted vielbein and its spin connection.

```
beta, b0 = sp.symbols("beta b0", real=True)  # the rate and the start of the rapidity
b = beta * x4 + b0  # the rapidity grows with the time
L = boost(b)
e_boosted = L * e  # e'^a_mu = sum_c Lambda^a_c e^c_mu
```

Two symbols, the rate β and the starting value b_0, and the rapidity $b = \beta x_4 + b_0$, which grows with the time. `e_boosted` is the matrix product $\Lambda(b)\, e$, the boosted vielbein $e'^{a}{}_{\mu} = \sum_c \Lambda^{a}{}_{c} e^{c}{}_{\mu}$.

```
check(matrix_is_zero(e_boosted.T * eta_matrix * e_boosted - g),
      "the boosted vielbein gives the author's metric (64 entries)",
      record=f"{SCOPE_PY}, check boosted_frame_reproduces_metric (b4 = 1)")
```

The check computes all 64 entries of $e'^{T} \eta e'$ and compares them with the author's metric.

```
omega_b = spin_connection(e_boosted, Gam, x, ETA)  # omega'_{mu ab}
postulate = [sp.diff(e_boosted[a, nu], x[mu])
             - sum(Gam[lam][mu][nu] * e_boosted[a, lam] for lam in range(8))
```

```
            + sum(ETA[a] * omega_b[mu][a][c] * e_boosted[c, nu] for c in range(8))
            for mu in range(8) for a in range(8) for nu in range(8)]
antisymmetric = all(is_zero(omega_b[mu][a][c] + omega_b[mu][c][a])
                    for mu in range(8) for a in range(8) for c in range(8))
check(all(is_zero(v) for v in postulate) and antisymmetric,
      "boosted vielbein: vielbein postulate (512) and antisymmetry of omega'",
      record=f"{SCOPE_PY}, check boosted_frame_canonical_connection (b4 = 1)")
```

The canonical spin connection of the boosted frame, computed by the general function (with the same Christoffel symbols `Gam`, because the metric is the same). Then the vielbein postulate in all 512 components and the antisymmetry, as in Notebook 06a, In [11], but with the boosted vielbein; one check for both. This is the slowest step of the notebook: every entry contains cosh and sinh of $\beta x_4 + b_0$, and sympy must simplify them.

```
Omega_b = spinor_connection(omega_b, S)  # Omega'_mu
gup_b = curved_gammas(e_boosted, gamma)  # gamma'^mu
count_b = sum(1 for mu in range(8) for a in range(8) for c in range(a + 1, 8)
              if omega_b[mu][a][c] != 0)
say(f"nonzero components omega'_mu ab with a < b: {count_b}")
```

The boosted spinor connection Ω'_μ, the boosted curved gammas γ'^μ, and the number of nonzero components $\omega'_{\mu ab}$ with $a < b$, printed: 13. The cell prints two PASS lines and this number.

In [8], the contraction in the boosted frame.

```
slash_b = sum((gup_b[mu] * Omega_b[mu] for mu in range(8)), Z16)
v = sp.cosh(b) * gamma[0] - sp.sinh(b) * gamma[4]  # R gamma^(x0) R^-1 (Section 11)
w = sp.cosh(b) * gamma[4] - sp.sinh(b) * gamma[0]  # R gamma^(x4) R^-1
formula = (6 * H - beta) / 2 * v + c_b4 * w
check(matrix_is_zero(slash_b - formula),
      "gamma'^mu Omega'_mu = ((6H - beta)/2) v + (3/4)(b4'/b4) w",
      record=f"{SCOPE_PY}, check boosted_frame_gammaOmega_formula (b4 = 1)")
```

`slash_b` is $\sum_\mu \gamma'^\mu \Omega'_\mu$; `v` and `w` are the matrices $\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}$ and $\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)}$ of Section 6.16 (In [12] checks that they are $R\gamma^{(x0)}R^{-1}$ and $R\gamma^{(x4)}R^{-1}$), and `formula` is $\frac{6H-\beta}{2}v + \frac{3}{4}\frac{b'_4}{b_4}w$, which at $b_4 = 1$ is the record's formula. The check requires them to be equal for symbolic a_4, b_4, H, β and b_0.

```
check(matrix_is_zero(formula.subs({beta: 0, b0: 0}) - 3 * H * gamma[0]
                     - c_b4 * gamma[4])
      and matrix_is_zero(at_b4_1(formula) - (6 * H - beta) / 2 * v),
      "with no boost the formula is 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4); at "
      "b4 = 1 it is ((6H - beta)/2) v")
```

With $\beta = b_0 = 0$ the formula must give back $3H\gamma^{(x0)} + \frac{3}{4}(b'_4/b_4)\gamma^{(x4)}$ (`.subs` with a dictionary replaces both symbols), and at $b_4 = 1$ it must be $\frac{6H-\beta}{2}v$. Two PASS lines.

In [9], figure 2.

```
times = np.linspace(-0.25, 0.25, 101)
t_symbol = sp.Symbol("t", real=True)
coefficient_x0 = (6 * H - beta) / 2 * sp.cosh(b)  # the coefficient of gamma^(x0)
coefficient_x4 = -(6 * H - beta) / 2 * sp.sinh(b)  # the coefficient of gamma^(x4)
```

101 times from -0.25 to 0.25, a plain symbol `t` for the time, and the two coefficients of the formula on the background $b_4 = 1$: of $\gamma^{(x0)}$, $\frac{6H-\beta}{2}\cosh b$, and of $\gamma^{(x4)}$, $-\frac{6H-\beta}{2}\sinh b$.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2), sharey=True)
for rate, style in ((0, "-"), (3, "--"), (6, "-."), (9, ":")):
    values = {H: 1, beta: rate, b0: 0, x4: t_symbol}
    c0 = sp.lambdify(t_symbol, coefficient_x0.subs(values))
    c4 = sp.lambdify(t_symbol, coefficient_x4.subs(values))
    ax_left.plot(times, np.broadcast_to(c0(times), times.shape), style,
                 label=f"$\\beta = {rate}H$" if rate else "no boost")
    ax_right.plot(times, np.broadcast_to(c4(times), times.shape), style,
                  label=f"$\\beta = {rate}H$" if rate else "no boost")
```

For the four rates $\beta = 0, 3, 6, 9$ (with $H = 1$ and $b_0 = 0$, so $b = \beta x_4$), each with its own line style, the two coefficients become numerical functions of the time and are plotted, the first on the left and the second on the right. `np.broadcast_to` makes a constant into a list of 101 values (for $\beta = 6$ both coefficients are the constant 0, for $\beta = 0$ the $\gamma^{(x0)}$ coefficient is the constant 3). The label is "no boost" for the rate 0 (the number 0 counts as false in `if rate`).

```
ax_left.set_title("coefficient of $\\gamma^{(x0)}$")
ax_right.set_title("coefficient of $\\gamma^{(x4)}$")
for ax in (ax_left, ax_right):
    ax.set_xlabel("time $x_4$ (units $1/H$), with $b = \\beta x_4$")
    ax.legend(fontsize=8)
ax_left.set_ylabel("coefficient in $\\gamma'^\\mu\\Omega'_\\mu$ (units of $H$)")
```

Titles, axis labels and legends.

```
save_figure(fig, "boosted_contraction",
            "The contraction $\\gamma'^\\mu\\Omega'_\\mu$ in the boosted vielbein with "
            ...
            "the same metric, a different frame, a different value. A changing "
            "$b_4$ would add $\\frac34(b_4'/b_4)(\\cosh b\\,\\gamma^{(x4)} - "
            "\\sinh b\\,\\gamma^{(x0)})$.")
```

The figure is saved; the cell prints its file name.

What Figure 06b.2 shows. Without boost (solid) the coefficients are the constants 3 and 0: the value $3H\gamma^{(x0)}$ of the diagonal vielbein at $b_4 = 1$. For $\beta = 3H$ (dashed) the $\gamma^{(x0)}$ coefficient is about $1.5\cosh(3x_4)$, smaller and slightly curved, and a $\gamma^{(x4)}$ coefficient appears. For $\beta = 6H$ (dash-dotted) both coefficients are zero at every time. For $\beta = 9H$ (dotted) they change sign. The same metric, a different frame, a different value of $\gamma^\mu\Omega_\mu$.

In [10], the rate $\beta = 6H$.

```
six_H = {beta: 6 * H}
slash_6H = slash_b.subs(six_H)
Omega_6H = [M.subs(six_H) for M in Omega_b]
nonzero = [NAMES[mu] for mu in range(8) if not matrix_is_zero(Omega_6H[mu])]
say(f"Omega'_mu is nonzero for mu = {nonzero}")
```

`six_H` replaces β by $6H$; substituting after the computation is allowed, because the computation was done for every β. `nonzero` lists the directions μ whose Ω'_μ is not the zero matrix and is printed: `['x1', 'x2', 'x3', 'x4', 'x5', 'x6', 'x7']`.

```
check(matrix_is_zero(slash_6H - c_b4 * w.subs(six_H))
      and matrix_is_zero(at_b4_1(slash_6H))
      and nonzero == NAMES[1:],
      "beta = 6H: gamma'^mu Omega'_mu = (3/4)(b4'/b4) w (zero for constant b4), "
      "Omega'_mu nonzero for x1 ... x7",
      record=f"{SCOPE_PY}, check boosted_frame_gammaOmega_vanishes (b4 = 1)")
```

The check requires the contraction to be $\frac{3}{4}(b_4'/b_4)\,w$ (with $\beta = 6H$ put into `w` too), to vanish identically at $b_4 = 1$, and Ω'_μ to be nonzero exactly for $x1, \ldots, x7$ (`NAMES[1:]` is the list of the names after the first). One line and one PASS line.

In [11], figure 3.

```
def at_sample(expr):
    """The decimal value of expr at H = 1, b0 = 0, x4 = 1/6, z = pi/4, a4 = 1/2,
    a4' = 1/2, a4'' = 0, b4 = 1 (derivatives replaced first, then a4 and b4, then
    x4)."""
    expr = at_b4_1(expr).subs(sp.Derivative(a4, (x4, 2)), 0)
    expr = expr.subs(sp.Derivative(a4, x4), sp.Rational(1, 2))
    expr = expr.subs(a4, sp.Rational(1, 2))
    expr = expr.subs({H: 1, b0: 0, x4: sp.Rational(1, 6), x0: sp.pi / 24})
    return float(sp.N(expr))
```

The sample point of this notebook: $H = 1$, $b_0 = 0$, $x_4 = \frac{1}{6}$ (so that $b = 6Hx_4 = 1$), $z = \pi/4$, $a_4 = \frac{1}{2}$, $a_4' = \frac{1}{2}$, $a_4'' = 0$, on the background $b_4 = 1$ (`at_b4_1` first), with the derivatives replaced first (Section 6.14, In [10] of Notebook 06a, explains why). `float` gives an ordinary decimal number.

```
def sample_table(matrix):
    return np.array([[at_sample(v) for v in row] for row in matrix.tolist()])
```

`sample_table` turns a matrix into an array of its decimal values at the sample point.

```
panels = [("$\\Omega'_{x4}$", Omega_6H[4]), ("$\\Omega'_{x1}$", Omega_6H[1]),
          ("$\\gamma'^\\mu\\Omega'_\\mu$ (all zero)", slash_6H)]
tables = [sample_table(M) for _, M in panels]
```

The three matrices of the figure: Ω'_{x4}, Ω'_{x1} and the contraction, and their tables.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 3.6))
for ax, (title, _), table in zip(axes, panels, tables):
    limit = max(np.abs(table).max(), 1.0)  # each panel its own colour scale
    image = ax.imshow(table, cmap="RdBu_r", vmin=-limit, vmax=limit)
    ax.set_title(title)
    ax.set_xticks([])
    ax.set_yticks([])
    ax.grid(False)
    fig.colorbar(image, ax=ax, shrink=0.8)
```

Three heat maps side by side, each with its own symmetric colour scale; `max(..., 1.0)` keeps the scale at least ± 1, so that the zero matrix is drawn white and not with an undefined scale.

```
save_figure(fig, "boosted_connection_heat_maps",
            "The boosted vielbein with the rate $\\beta = 6H$ at the sample point "
            ...
            "zero matrix. The spinor connection is present, its contraction is not.")
```

The figure is saved.

```
check(np.abs(tables[2]).max() < 1e-12 and np.abs(tables[0]).max() > 0.1,
      "at the sample point Omega'_x4 is nonzero and the contraction is zero")
```

A numerical check of what the picture shows: the largest entry of the contraction is below 10^{-12}, and the largest entry of Ω'_{x4} is above 0.1. The cell prints the file name and one PASS line.

What Figure 06b.3 shows. At the sample point $b_4 = 1$. The left panel, Ω'_{x4}, is coloured, although $\Omega_{x4} = 0$ in the diagonal vielbein: in the boosted frame the frame turns with the time, at the rate $\beta = 6H$, and $\Omega'_{x4} = 3H\gamma^{(x4)}\gamma^{(x0)}$ (Section 6.16), a signed permutation matrix times 3 whose squares lie in the two diagonal blocks. The middle panel, Ω'_{x1}, is coloured too. The right panel is white: the contraction of the two is the zero matrix. The spinor connection is present; its contraction is not.

In [12], why: the explicit spinor boost (Sections 6.15 and 6.16).

```
X = gamma[4] * gamma[0]  # gamma^(x4) gamma^(x0)
check(X * X == I16, "X = gamma^(x4) gamma^(x0) squares to the identity")
R = sp.cosh(b / 2) * I16 - sp.sinh(b / 2) * X  # the spinor boost
R_inv = sp.cosh(b / 2) * I16 + sp.sinh(b / 2) * X
check(matrix_is_zero(R * R_inv - I16), "R R^-1 = 1")
```

$X = \gamma^{(x4)}\gamma^{(x0)}$ and the check $X^2 = 1$; the spinor boost $R = \cosh\frac{b}{2} - \sinh\frac{b}{2}X$ and its inverse $\cosh\frac{b}{2} + \sinh\frac{b}{2}X$, and the check $RR^{-1} = 1$.

```
covers = all(matrix_is_zero(R_inv * gamma[a] * R
                            - sum((L[a, c] * gamma[c] for c in range(8)), Z16))
             for a in range(8))
check(covers, "R^-1 gamma^a R = Lambda^a_c gamma^c: R covers the boost")
```

The covering relation $R^{-1}\gamma^a R = \sum_c \Lambda^a{}_c\gamma^c$ for all eight a (`L[a, c]` is $\Lambda^a{}_c$ for the rapidity $b = \beta x_4 + b_0$).

```
gammas_turn = all(matrix_is_zero(gup_b[mu] - R * gup[mu] * R_inv) for mu in range(8))
connection_rule = all(matrix_is_zero(Omega_b[mu] - (R * Omega[mu] * R_inv
                                                    - R.diff(x[mu]) * R_inv))
                      for mu in range(8))
check(gammas_turn and connection_rule,
      "gamma'^mu = R gamma^mu R^-1 and Omega'_mu = R Omega_mu R^-1 - (d_mu R) R^-1")
```

The theorem of Section 6.15 for this boost: $\gamma'^{\mu} = R\gamma^{\mu}R^{-1}$ and $\Omega'_{\mu} = R\Omega_{\mu}R^{-1} - (\partial_{\mu}R)R^{-1}$ for all eight μ (`R.diff(x[mu])` differentiates every entry of R).

```
turned = R * slash * R_inv
extra = sum((gup_b[mu] * R.diff(x[mu]) * R_inv for mu in range(8)), Z16)
check(matrix_is_zero(R * gamma[0] * R_inv - v)
      and matrix_is_zero(R * gamma[4] * R_inv - w)
      and matrix_is_zero(turned - 3 * H * v - c_b4 * w)
      and matrix_is_zero(extra - beta / 2 * v),
      "R g0 R^-1 = v, R g4 R^-1 = w; turned term 3H v + (3/4)(b4'/b4) w; extra term "
      "(beta/2) v")
```

The two pieces of the formula: `turned` is $R\left(\sum_{\mu}\gamma^{\mu}\Omega_{\mu}\right)R^{-1}$ with the contraction `slash` of In [4], and `extra` is $\sum_{\mu}\gamma'^{\mu}(\partial_{\mu}R)R^{-1}$. The check requires $R\gamma^{(x0)}R^{-1} = v$, $R\gamma^{(x4)}R^{-1} = w$, `turned` $= 3Hv + \frac{3}{4}\frac{b'_4}{b_4}w$ and `extra` $= \frac{\beta}{2}v$, as derived by hand in Section 6.16. The cell prints five PASS lines.

In [13], the Riemann and Ricci tensors (Section 6.17).

```
def riemann_component(r, sg, mu, nu):
    value = sp.diff(Gam[r][nu][sg], x[mu]) - sp.diff(Gam[r][mu][sg], x[nu])
    for lam in range(8):
        value += Gam[r][mu][lam] * Gam[lam][nu][sg] - Gam[r][nu][lam] * Gam[lam][mu][sg]
    return value
```

`riemann_component(r, sg, mu, nu)` is $R^{r}{}_{\sigma\mu\nu}$ by the formula of Section 6.17 (`sg` stands for σ).

```
def is_nonzero(expr):
    """True when expr is not identically zero.  A value clearly different from zero
    at the sample point proves it (fast); otherwise the exact test decides."""
    if abs(at_sample(expr)) > 1e-9:
        return True
    return not is_zero(expr)
```

`is_nonzero(expr)` decides whether an expression is not identically zero. If its value at the sample point is clearly different from zero, that proves it at once (a function that is not zero at one point is not the zero function); otherwise the exact test decides.

```
riemann = {}  # (r, sigma, mu, nu) -> R^r_sigma mu nu, only the nonzero ones
for r in range(8):
    for sg in range(8):
        for mu in range(8):
```

```
            for nu in range(mu + 1, 8):
                value = riemann_component(r, sg, mu, nu)
                if value != 0 and is_nonzero(value):
                    riemann[(r, sg, mu, nu)] = value
                    riemann[(r, sg, nu, mu)] = -value
report("nonzero components R^r_sigma mu nu with mu < nu", len(riemann) // 2)
```

All components with $\mu < \nu$ are computed (the others follow from the antisymmetry $R^{\rho}{}_{\sigma\nu\mu} = -R^{\rho}{}_{\sigma\mu\nu}$, which the two assignments use). `value != 0` first skips the components that are zero without any work. The RESULT line prints the number of nonzero components with $\mu < \nu$: 78 (`//` is division without remainder; the dictionary holds every component twice).

```
ricci_lower = sp.Matrix(8, 8, lambda sg, nu: sum(
    riemann.get((r, sg, r, nu), 0) for r in range(8)))  # R_sigma nu
ricci_mixed = g.inv() * ricci_lower  # R^mu_nu = g^mu sigma R_sigma nu
```

The Ricci tensor $R_{\sigma\nu} = \sum_r R^{r}{}_{\sigma r\nu}$ as an 8×8 matrix (`sp.Matrix(8, 8, function)` fills each entry with the value of the function of its row and its column; `riemann.get(key, 0)` gives 0 for a missing key), and the mixed Ricci tensor $R^{\mu}{}_{\nu} = \sum_{\sigma} g^{\mu\sigma} R_{\sigma\nu}$ as the matrix product with the inverse metric.

```
names = {"H": H, "x0": x0, "x4": x4, "a4": a4, "b4": b4, "a4p": a4p, "b4p": b4p,
         "a4pp": sp.Derivative(a4, (x4, 2)), "b4pp": sp.Derivative(b4, (x4, 2))}

def wolfram_to_sympy(text):
    for long_form, short_form in (("Derivative[1][a4][x4]", "a4p"),
                                  ("Derivative[2][a4][x4]", "a4pp"),
                                  ("Derivative[1][b4][x4]", "b4p"),
                                  ("Derivative[2][b4][x4]", "b4pp"),
                                  ("a4[x4]", "a4"), ("b4[x4]", "b4")):
        text = text.replace(long_form, short_form)
    return parse_mathematica(text).subs(
        {sp.Symbol(k): value for k, value in names.items()}, simultaneous=True)
```

`names` says which symbol or function of the notebook each plain name of the records means, and `wolfram_to_sympy(text)` reads a text of a record in Wolfram notation, as the function of the same name in Notebook 06a, In [3], here with the fixed dictionary `names`.

```
metric_b4 = json.loads(repository_file(METRIC_B4_FILE).read_text(encoding="utf-8"))
ricci_b4 = {tuple(NAMES.index(n) for n in key.split(",")): wolfram_to_sympy(text)
            for key, text in metric_b4["ricciMixed"].items()}
nonzero_mixed = {(m, n) for m in range(8) for n in range(8)
                 if not is_zero(ricci_mixed[m, n])}
check(nonzero_mixed == set(ricci_b4)
      and all(is_zero(ricci_mixed[k] - ricci_b4[k]) for k in ricci_b4)
      and is_zero(sum(ricci_mixed[a, a] for a in range(8))
                  - wolfram_to_sympy(metric_b4["ricciScalar"])),
      "the mixed Ricci tensor (10 nonzero components, 2 off the diagonal) and R equal "
      "the record with b4",
      record=f"{METRIC_B4_FILE}, keys ricciMixed and ricciScalar")
```

The record `metric-b4.json` stores the mixed Ricci tensor of the metric with b_4 under the key `ricciMixed`, as a dictionary whose keys are texts such as `"x4,x0"` (first the upper index, then the lower one) and whose values are the nonzero components; `key.split(",")` cuts a key at the comma, and `NAMES.index` turns each name into its position. `nonzero_mixed` is the set of the positions at which the computed mixed Ricci tensor is not zero. The check requires the same ten positions, the same values, and the Ricci scalar, the sum of the eight diagonal entries, equal to the record's `ricciScalar`.

```
for key in sorted(ricci_b4):
    say(f"R^{NAMES[key[0]]}_{NAMES[key[1]]} = {ricci_b4[key]}")
FORMULAS = {item["key"]: item["wl"] for item in json.loads(
    repository_file(THEORY_FILE).read_text(encoding="utf-8"))["formulas"]}
```

The loop prints the ten components in the order of their positions (`sorted` orders the pairs by the first number, then by the second): ${R^{x0}}_{x0} = -6H^2$, ${R^{0}}_{x4} = -\frac{3}{2}H \tan z\, b_4'/b_4$, the three 3-space components, ${R^{x4}}_{x0} = \frac{3}{2}H \cot z\, b_4'/b_4$, ${R^{x4}}_{x4}$ and the three extra-time components, each in sympy's form. `FORMULAS` holds the formulas of the record of $b_4 = 1$.

```
ricci_record = wolfram_to_sympy(FORMULAS["ricci_mixed_diagonal"])
ricci_scalar = sum(ricci_mixed[a, a] for a in range(8))
check(all(is_zero(at_b4_1(ricci_mixed[a, a]) - ricci_record[a]) for a in range(8))
      and is_zero(at_b4_1(ricci_scalar) - wolfram_to_sympy(FORMULAS["ricci_scalar"])),
      "at b4 = 1: the eight Ricci components and R = 6 (a4'^2 - 7 H^2) equal the record",
      record=f"{THEORY_FILE}, formulas ricci_mixed_diagonal and ricci_scalar")
```

At $b_4 = 1$ (`at_b4_1`) the eight diagonal components are compared with the record's `ricci_mixed_diagonal`, $-6H^2$, three times $-6H^2 + a_4''$, $6a_4'^2$ and three times $-6H^2 - a_4''$, and the Ricci scalar with the record's $6(a_4'^2 - 7H^2)$.

```
# multiplied out, the entries of gamma^mu Omega_mu contain neither a4 nor its derivatives
a4_free = all(not sp.expand(entry).has(a4) for entry in slash)
check(a4_free and is_zero(ricci_mixed[0, 0] + 6 * H**2)
      and is_zero(at_b4_1(ricci_mixed[4, 4]) - 6 * a4p ** 2),
      "gamma^mu Omega_mu contains no a4, but R^x4_x4 = 6 a4'^2 at b4 = 1; "
      "R^x0_x0 = -6 H^2 for every b4",
      record=f"{SCOPE_PY}, check gammaOmega_blind_to_the_deflation (b4 = 1)")
```

The last check: multiplied out (`sp.expand`), no entry of the contraction `slash` of In [4] contains a_4 (`.has(a4)` is true also for an expression with a_4', which contains a_4), while ${R^{x0}}_{x0} = -6H^2$ for every b_4 and ${R^{x4}}_{x4} = 6a_4'^2$ at $b_4 = 1$. The cell prints one RESULT line, ten component lines and three PASS lines.

In [14], figure 4.

```
rate_symbol, accel_symbol = sp.symbols("rate accel", real=True)
numeric = [sp.lambdify((rate_symbol, accel_symbol), ricci_record[a].subs(
    {H: 1, sp.Derivative(a4, (x4, 2)): accel_symbol,
     sp.Derivative(a4, x4): rate_symbol})) for a in range(8)]
```

The eight Ricci components of the record of $b_4 = 1$ as numerical functions of two plain symbols, the rate a_4' and the acceleration a_4'', with $H = 1$.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
values = [float(numeric[a](0.5, 0.0)) for a in range(8)]
colors = ["black"] + ["tab:red"] * 3 + ["gray"] + ["tab:blue"] * 3
ax_left.bar(range(8), values, color=colors, width=0.6)
ax_left.axhline(0.0, color="black", linewidth=0.8)
ax_left.set_xticks(range(8), [f"$R^{{{n}}}{{}}_{{{n}}}$" for n in NAMES], fontsize=8)
ax_left.set_ylabel("value (units of $H^2$)")
ax_left.set_title("Ricci components at $a_4' = 1/2$, $a_4'' = 0$, $b_4 = 1$")
```

The left panel: a bar chart of the eight components at $a_4' = \frac{1}{2}$, $a_4'' = 0$, coloured by kind (black hidden direction, red 3-space, gray time, blue extra times), with labels such as $R^{x1}{}_{x1}$ under the bars.

```
rates = np.linspace(-3.0, 3.0, 121)
for a, label, style in ((0, "$R^{x0}{}_{x0} = -6H^2$", "-"),
                        (4, "$R^{x4}{}_{x4} = 6a_4'^2$", "--"),
                        (1, "$R^{x1}{}_{x1} = a_4'' - 6H^2$", ":")):
    ax_right.plot(rates, np.broadcast_to(numeric[a](rates, 0.0), rates.shape),
                  style, label=label)
ax_right.axhline(0.0, color="black", linewidth=0.8)
ax_right.set_xlabel("rate $a_4'$ (units of $H$), with $a_4'' = 0$, $b_4 = 1$")
ax_right.set_ylabel("value (units of $H^2$)")
ax_right.set_title("Never flat: $R^{x0}{}_{x0} = -6H^2$")
ax_right.legend(fontsize=8)
```

The right panel: three components versus the rate a_4' from -3 to 3 with $a_4'' = 0$: $R^{x0}{}_{x0}$ (solid), $R^{x4}{}_{x4}$ (dashed) and $R^{x1}{}_{x1}$ (dotted).

```
save_figure(fig, "ricci_components",
            "The mixed Ricci components $R^\\mu{}_\\mu$ of the author's metric on the "
            "background $b_4 = 1$, in units of $H^2$. Left: all eight at $H = 1$, "
            "$a_4' = 1/2$, $a_4^{\\prime\\prime} = 0$ (black: hidden direction, red: "
            "3-space, gray: time, blue: extra times). Right: $R^{x0}{}_{x0} = -6H^2$ "
            "(solid), $R^{x4}{}_{x4} = 6a_4'^2$ (dashed) and $R^{x1}{}_{x1} = "
            ...
            "is negative for every history (and every $b_4$), so the metric is never "
            "flat, and the time component is curvature made by the expansion and "
            "deflation (the dotted line lies on the solid one because "
            "$a_4^{\\prime\\prime} = 0$).")
```

The figure is saved; the cell prints its file name.

What Figure 06b.4 shows. On the background $b_4 = 1$. On the left, the six warped bars and the hidden bar lie at -6 (with $a_4'' = 0$ the 3-space and extra-time components are both $-6H^2$), while the time bar is $6 \cdot \frac{1}{4} = 1.5$. On the right, the solid line is flat at -6 for every rate: the hidden component is negative for every history (and every b_4), so the metric is never flat. The dashed parabola $6a_4'^2$ is curvature made by the inflation and deflation alone; it vanishes only for a constant a_4. The dotted line lies on the solid one because $a_4'' = 0$.

In [15], the spinor curvature (Section 6.17).

```
def spinor_curvature(Om, mu, nu):
    return (Om[nu].diff(x[mu]) - Om[mu].diff(x[nu])
            + Om[mu] * Om[nu] - Om[nu] * Om[mu])
```

`spinor_curvature(Om, mu, nu)` is $F_{\mu\nu} = \partial_\mu \Omega_\nu - \partial_\nu \Omega_\mu + [\Omega_\mu, \Omega_\nu]$ for any list of spinor connections `Om`.

```
F = {}
theorem_ok = True
for mu in range(8):
    for nu in range(mu + 1, 8):
        F[(mu, nu)] = spinor_curvature(Omega, mu, nu)
        from_riemann = sum((ETA[a] * f[a] * riemann[(a, c, mu, nu)] / f[c] * S[a][c] / 2
                            for a in range(8) for c in range(8)
                            if (a, c, mu, nu) in riemann), Z16)
        theorem_ok = theorem_ok and matrix_is_zero(F[(mu, nu)] - from_riemann)
check(theorem_ok and record_passed(REPORT_WL_B4, "spin_curvature_equals_Riemann"),
      "F_mu nu = (1/2) R_ab mu nu S^ab in all 28 coordinate planes",
      record=f"{REPORT_WL_B4}, check spin_curvature_equals_Riemann")
```

For the 28 planes $\mu < \nu$ of the diagonal vielbein, $F_{\mu\nu}$ is computed and compared with $\frac{1}{2}\sum_{a,c} R_{ac\mu\nu} S^{ac}$, where $R_{ac\mu\nu} = \eta_{aa} f_a R^a{}_{c\mu\nu} / f_c$ (the term is added only when the Riemann component is nonzero, `if (a, c, mu, nu) in riemann`). The check requires the theorem in all 28 planes, for every b_4, and the WolframScript report with b_4 to record the same.

```
F01_boosted = spinor_curvature(Omega_6H, 0, 1)
R_6H, R_inv_6H = R.subs(six_H), R_inv.subs(six_H)
check(matrix_is_zero(F01_boosted - R_6H * F[(0, 1)] * R_inv_6H)
      and np.abs(sample_table(F01_boosted)).max() > 0.1,
      "boosted (beta = 6H): F'_x0x1 = R F_x0x1 R^-1, nonzero",
      record=f"{SCOPE_PY}, check boosted_frame_curvature_nonzero (b4 = 1)")
```

In the boosted frame with $\beta = 6H$: $F'_{x0\,x1}$ is computed from the boosted spinor connection, R and R^{-1} are taken at $\beta = 6H$, and the check requires $F'_{x0x1} = R F_{x0x1} R^{-1}$ and an entry above 0.1 at the sample point, so that it is not zero. Two PASS lines with their records.

In [16], figure 5.

```
norms = np.zeros((8, 8))
for (mu, nu), matrix in F.items():
    norms[mu, nu] = norms[nu, mu] = np.sqrt((sample_table(matrix) ** 2).sum())
```

For each plane the size $\|F_{\mu\nu}\|$, the square root of the sum of the squares of its 256 entries at the sample point (`** 2` squares every entry, `.sum()` adds them), stored symmetrically in an 8×8 array.

```
fig, ax = plt.subplots(figsize=(6.4, 5.4))
image = ax.imshow(norms, cmap="Purples")
for mu in range(8):
    for nu in range(8):
```

```
        if norms[mu, nu] > 0:
            # white digits on the dark squares (the largest sizes), black elsewhere
            dark = norms[mu, nu] > 0.6 * norms.max()
            ax.text(nu, mu, f"{norms[mu, nu]:.1f}", ha="center", va="center",
                    fontsize=7, color="white" if dark else "black")
ax.set_xticks(range(8), NAMES)
ax.set_yticks(range(8), NAMES)
ax.set_xlabel("coordinate $\\nu$")
ax.set_ylabel("coordinate $\\mu$")
ax.set_title("Size of the spinor curvature $\\|F_{\\mu\\nu}\\|$")
ax.grid(False)
fig.colorbar(image, ax=ax, shrink=0.8, label="$\\|F_{\\mu\\nu}\\|$ (units of $H^2$)")
```

A heat map in shades of purple (white is zero), with the size written into each nonzero square with one decimal, in white on the dark squares (above 60 percent of the largest size) and in black elsewhere, and a colour bar.

```
save_figure(fig, "spinor_curvature_norms",
            "The size $\\|F_{\\mu\\nu}\\|$, the square root of the sum of the squares "
            ...
            "change of frame removes.")
```

The figure is saved.

```
report("largest |F_mu nu| at the sample point (units of H^2)", f"{norms.max():.3f}")
curved = [pair for pair in F if norms[pair] > 1e-9]  # the curved planes
check(matrix_is_zero(F[(0, 4)]) and len(curved) == 27,
      "F_x0x4 = 0 exactly (every b4); the other 27 planes are curved at the sample "
      "point")
```

The RESULT line prints the largest size, 3.633 (in units of H^2). `curved` lists the planes with a size above 10^{-9}, and the check requires $F_{x0x4} = 0$ exactly and the other 27 planes to be curved at the sample point.

What Figure 06b.5 shows. At the sample point $b_4 = 1$. Every square off the diagonal is coloured except the two of the pair $(x0, x4)$. The largest sizes, about 3.6 and 3.5, lie in the planes within 3-space and between 3-space and the hidden direction; the planes of 3-space with the extra times have about 2.2, with the time about 1.7; the planes of the extra times among themselves about 0.5, with the time 0.6 and with the hidden direction 1.3. The pattern reflects the factors e^{a_4} and e^{-a_4} at $a_4 = \frac{1}{2}$. Whatever the numbers in another frame, $F' = RFR^{-1}$ can never turn a coloured square white: this curvature is a property of the metric.

In [17], the rescaling (Section 6.18).

```
w_r = sp.sin(z) ** sp.Rational(-1, 2) * b4 ** sp.Rational(-3, 4)  # the weight
bracket = sum((gup[mu] * sp.diff(w_r, x[mu]) for mu in range(8)), Z16) + w_r * slash
```

The weight $w = \sin^{-1/2}(z)\, b_4^{-3/4}$ (named `w_r` in the code) and the bracket $\sum_\mu \gamma^\mu \partial_\mu w + w \sum_\mu \gamma^\mu \Omega_\mu$ of Section 6.18.

```
chi = sp.Matrix([sp.Function(f"chi{A}")(*x) for A in range(1, 17)])
psi = w_r * chi
dirac_psi = sum((gup[mu] * (psi.diff(x[mu]) + Omega[mu] * psi) for mu in range(8)),
                sp.zeros(16, 1))
dirac_chi = sum((gup[mu] * chi.diff(x[mu]) for mu in range(8)), sp.zeros(16, 1))
check(matrix_is_zero(bracket) and all(is_zero(v) for v in dirac_psi - w_r * dirac_chi),
      "gamma^mu D_mu (w chi) = w gamma^mu d_mu chi for w = sin^(-1/2) z b4^(-3/4)",
      record=f"{SCOPE_PY}, check rescaling_removes_the_connection_term (b4 = 1)")
```

For safety the statement is also checked on sixteen completely general functions $\chi_1, \ldots, \chi_{16}$ of all eight coordinates: `dirac_psi` is $\sum_\mu \gamma^\mu D_\mu(w\chi)$ and `dirac_chi` is $\sum_\mu \gamma^\mu \partial_\mu \chi$; the check requires the bracket to vanish and $\sum_\mu \gamma^\mu D_\mu(w\chi) - w \sum_\mu \gamma^\mu \partial_\mu \chi$ to vanish in all sixteen components.

```
chi_conj = sp.Matrix([sp.conjugate(v) for v in chi])  # complex conjugates
S_psi = (w_r * chi_conj).T * C * (w_r * chi)  # Psi^dagger C Psi (w is real)
S_chi = chi_conj.T * C * chi
check(is_zero(S_psi[0, 0] - S_chi[0, 0] / (b4 ** sp.Rational(3, 2) * sp.sin(z))),
      "S[w chi] = S[chi] / (b4^(3/2) sin z), S[chi] / sin z at b4 = 1",
      record=f"{SCOPE_PY}, check rescaled_equation_quadratic_potential (b4 = 1)")
```

The bilinear: `chi_conj` is the column of the complex conjugates χ_A^*, so `(w * chi_conj).T * C * (w * chi)` is $\Psi^\dagger C \Psi$ for $\Psi = w\chi$ (the conjugate of the real w is w), a 1×1 matrix whose only entry `[0, 0]` is the number. The check requires $S[w\chi] = S[\chi]/(b_4^{3/2} \sin z)$. Two PASS lines with their records.

In [18], figure 6.

```
z_values = np.linspace(0.05, np.pi / 2 - 0.02, 300)
x0_symbol = sp.Symbol("u", positive=True)
w_1 = at_b4_1(w_r)  # the weight at b4 = 1: sin^(-1/2) z
term_derivative = sp.lambdify(x0_symbol, (sp.tan(z) * sp.diff(w_1, x0)).subs(
    {H: 1}).subs(x0, x0_symbol))
term_connection = sp.lambdify(x0_symbol, (3 * H * w_1).subs({H: 1}).subs(x0, x0_symbol))
weight = sp.lambdify(x0_symbol, w_1.subs({H: 1}).subs(x0, x0_symbol))
u_values = z_values / 6.0  # x0 = z / (6 H) with H = 1
first, second = term_derivative(u_values), term_connection(u_values)
```

300 values of z inside $(0, \pi/2)$; `w_1` is the weight at $b_4 = 1$, $\sin^{-1/2} z$; and three numerical functions of x_0 (a positive symbol `u` replaces x_0): the derivative term $\tan z\, \partial_0 w$, the connection term $3Hw$ and the weight w, all with $H = 1$ and $b_4 = 1$. With $H = 1$, $x_0 = z/6$.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
ax_left.plot(z_values, weight(u_values), label="$w_r = \\sin^{-1/2} z$ ($b_4 = 1$)")
ax_left.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax_left.set_ylabel("weight (pure number)")
ax_left.set_title("The rescaling weight")
ax_left.legend(fontsize=8)
ax_right.plot(z_values, first, label="$\\tan z\\,\\partial_{x0} w_r$")
ax_right.plot(z_values, second, "--",
              label="$3H w_r$ (from $\\gamma^\\mu\\Omega_\\mu$)")
```

```
ax_right.plot(z_values, first + second, ":", color="black", label="sum")
ax_right.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax_right.set_ylabel("coefficient of $\\gamma^{(x0)}\\chi$ (units of $H$)")
ax_right.set_title("The two terms cancel")
ax_right.legend(fontsize=8)
```

The left panel draws w; the right panel the two terms and their sum.

```
save_figure(fig, "rescaling",
            "The rescaling $\\Psi = w_r\\chi$ with $w_r = \\sin^{-1/2}(z)\\,"
            "b_4^{-3/4}$, drawn for $H = 1$ on the background $b_4 = 1$. Left: the "
            "weight $w_r$ versus the hidden angle $z$ in radians. Right: the two "
            "terms of the coefficient of $\\gamma^{(x0)}\\chi$ in the field "
            "equation of $\\chi$, the derivative term $\\tan z\\,\\partial_{x0}w_r = "
            "-3Hw_r$ (solid) and the spin-connection term $3Hw_r$ (dashed), in units "
            "of $H$, and their sum (dotted), which is zero at every $z$: in the "
            ...
            "variable $\\chi$ the equation has no term $3H\\gamma^{(x0)}$ (and, by "
            "the factor $b_4^{-3/4}$, no term $\\frac34(b_4'/b_4)\\gamma^{(x4)}$).")
```

The figure is saved.

```
check(np.max(np.abs(first + second)) < 1e-12, "the two terms cancel at all 300 points")
```

The two terms cancel at all 300 points to better than 10^{-12}. The cell prints the file name and one PASS line.

What Figure 06b.6 shows. On the background $b_4 = 1$. On the left, the weight $w = \sin^{-1/2} z$ is large near the tip $z \to 0$ and falls to 1 at the patch end. On the right, the derivative term $\tan z\, \partial_0 w = -3Hw$ (solid) is the mirror image of the connection term $3Hw$ (dashed) about the zero line, and their sum (dotted) lies on zero everywhere: in the variable χ the field equation has no term $3H\gamma^{(x0)}$ (and, by the factor $b_4^{-3/4}$ of the weight, no term $\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$).

In [19], the last checks.

```
scope_names = ["boosted_frame_reproduces_metric", "boosted_frame_canonical_connection",
               "boosted_frame_gammaOmega_formula", "boosted_frame_gammaOmega_vanishes",
               "boosted_frame_curvature_nonzero",
               "rescaling_removes_the_connection_term",
               "rescaled_equation_quadratic_potential",

check(all(record_passed(path, name) for path, names in cited.items()
          for name in names), f"the {count} cited record checks are recorded as passed")
```

`scope_names` lists the eight scope checks that this notebook reproduces; each appears in both scope reports, the sympy one and the WolframScript one. Together with two curvature checks of the sympy field-theory report and four of the WolframScript one (both of $b_4 = 1$), and three of the WolframScript report with b_4, that makes $8 + 8 + 2 + 4 + 3 = 25$ cited checks, and the check requires all of them to be recorded as passed.

```
expected = [f"06b_{k}_{name}.png" for k, name in enumerate([
    "boost_hyperbolas", "boosted_contraction", "boosted_connection_heat_maps",
    "ricci_components", "spinor_curvature_norms", "rescaling"], 1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected),
      "all six figure files exist")
all_checks_passed()
```

The six figure files must exist, and the last line is printed: ALL 26 CHECKS PASSED (notebook 06b).

6.23 Upper and lower frame indices: the mixed contraction

The issue. The spin connection comes out of its formula with the first frame index up, $\omega_\mu{}^a{}_b$ (the mixed components, Section 6.4), and the spinor connection is built from the components with both frame indices down, $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$ with $\omega_{\mu ab} = \eta_{aa}\omega_\mu{}^a{}_b$. The Revision record states (in `Revision/SPEC.md`, section 3, and in `Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`, section 4) that the author's Mathematica notebook contracts the mixed components with S^{ab} instead, that this contraction lacks one factor of the frame metric, and that the record does not use it. This book has not opened the author's notebook file; it relies on the record's statement, which Notebook 06c checks in `Revision/SPEC.md`. We call that contraction

$$\Omega^{nb}_\mu = \tfrac{1}{2}\sum_{a,b}\omega_\mu{}^a{}_b\,S^{ab}$$

("nb" for notebook) and derive exactly what the missing factor changes.

The derivation, line by line. Lowering is multiplication by η_{aa}, and $\eta_{aa}\eta_{aa} = 1$, so $\omega_\mu{}^a{}_b = \eta_{aa}\omega_{\mu ab}$ (multiply $\omega_{\mu ab} = \eta_{aa}\omega_\mu{}^a{}_b$ by η_{aa}). Hence

$$\Omega^{nb}_\mu = \tfrac{1}{2}\sum_{a,b}\eta_{aa}\,\omega_{\mu ab}\,S^{ab}.$$

The terms with $a = b$ vanish ($S^{aa} = 0$). Every other term belongs to exactly one unordered pair $\{a, b\}$ with $a < b$, which contributes two terms:

$$\eta_{aa}\,\omega_{\mu ab}S^{ab} + \eta_{bb}\,\omega_{\mu ba}S^{ba} = (\eta_{aa} + \eta_{bb})\,\omega_{\mu ab}S^{ab}$$

(both factors of the second term change sign when a and b are exchanged, $\omega_{\mu ba}S^{ba} = (-\omega_{\mu ab})(-S^{ab})$). So

$$\Omega_\mu^{nb} = \sum_{a<b} \tfrac{1}{2}(\eta_{aa}+\eta_{bb})\,\omega_{\mu ab} S^{ab}, \qquad \text{while} \qquad \Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$$

(the same steps without η, Section 6.7). The factor $\frac{1}{2}(\eta_{aa}+\eta_{bb})$ is $+1$ for a pair of two space-like directions (**space-space**), -1 for a pair of two time-like directions (**time-time**) and 0 for a boost pair. In the author's frame metric there are $\binom{4}{2} = 6$ space-space pairs among $x0, x1, x2, x3$, 6 time-time pairs among $x4, x5, x6, x7$, and $4 \cdot 4 = 16$ boost pairs. Writing Ω_μ^{ss}, Ω_μ^{tt} and Ω_μ^{st} for the parts of Ω_μ that come from the three kinds of pairs:

$$\Omega_\mu^{nb} = \Omega_\mu^{ss} - \Omega_\mu^{tt}, \qquad \Omega_\mu = \Omega_\mu^{ss} + \Omega_\mu^{tt} + \Omega_\mu^{st}.$$

The mixed contraction keeps the 6 space-space parts, reverses the sign of the 6 time-time parts and deletes all 16 boost parts. In a space whose metric is positive (every $\eta_{aa} = +1$) the factor is always $+1$ and the two contractions agree: in the polar plane of Section 6.5 both give $\Omega_\varphi = -\frac{i}{2}\sigma_3$. The mistake cannot be seen in the usual textbook examples; in signature (4,4) it deletes 16 of the 28 parts.

Where it is total: the Milne wedge. Take the flat plane with one time t and one space direction y, $ds^2 = -dt^2 + dy^2$, and in the part $t > |y|$ the coordinates $\tau = \sqrt{t^2 - y^2}$ and θ with $t = \tau\cosh\theta$, $y = \tau\sinh\theta$. Line by line, $dt = \cosh\theta\, d\tau + \tau\sinh\theta\, d\theta$ and $dy = \sinh\theta\, d\tau + \tau\cosh\theta\, d\theta$ (the product rule and $\frac{d}{d\theta}\cosh\theta = \sinh\theta$, $\frac{d}{d\theta}\sinh\theta = \cosh\theta$), so

$$-dt^2 + dy^2 = -(\cosh^2\theta - \sinh^2\theta)\, d\tau^2 + \tau^2(\cosh^2\theta - \sinh^2\theta)\, d\theta^2 = -d\tau^2 + \tau^2 d\theta^2$$

(square, add; the cross terms $\mp 2\tau\cosh\theta\sinh\theta\, d\tau\, d\theta$ cancel; $\cosh^2 - \sinh^2 = 1$). This part of the flat plane is called the **Milne wedge**. Its frame metric is $\eta = \mathrm{diag}(-1, +1)$ (frame index 0 the unit time direction, 1 the unit space direction) and its vielbein factors are $f_\tau = 1$, $f_\theta = \tau$. By the formula of Section 6.6, $\omega_{\theta\,10} = \eta_{11}\,\partial_\tau f_\theta / f_\tau = 1$, so $\omega_{\theta\,01} = -1$, and the mixed components are

$$\omega_\theta{}^0{}_1 = \eta_{00}\,\omega_{\theta 01} = (-1)(-1) = 1, \qquad \omega_\theta{}^1{}_0 = \eta_{11}\,\omega_{\theta 10} = 1 :$$

symmetric, as for every boost pair (Section 6.4). Two real 2×2 matrices with $(\gamma^0)^2 = -1$, $(\gamma^1)^2 = +1$ and $\gamma^0\gamma^1 + \gamma^1\gamma^0 = 0$ are $\gamma^0 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ and $\gamma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ (multiply out to check), with $\gamma^0\gamma^1 = \mathrm{diag}(1, -1)$. Then

$$\Omega_\theta = \omega_{\theta 01} S^{01} = -\tfrac{1}{2}\gamma^0\gamma^1, \qquad \Omega_\theta^{nb} = \tfrac{1}{2}(\omega_\theta{}^0{}_1 S^{01} + \omega_\theta{}^1{}_0 S^{10}) = \tfrac{1}{2}(S^{01} - S^{01}) = 0.$$

The plane is flat, but the frame is boosted by the rapidity θ as one moves along θ, and the correct spinor connection records this: $\Omega_\theta = -(\partial_\theta U)U^{-1}$ for the spinor boost $U(\theta) = \cosh\frac{\theta}{2} + \sinh\frac{\theta}{2}\,\gamma^0\gamma^1 = \mathrm{diag}(e^{\theta/2}, e^{-\theta/2})$ (since $\partial_\theta U = \frac{1}{2}\gamma^0\gamma^1 U$). As in the polar plane of Section 6.5, the rule $\Omega' = R\,\Omega R^{-1} - (\partial_\theta R)R^{-1}$ of Section 6.15 with $R = U$ makes this Ω_θ from the connection 0 of the frame of t and y, so U carries that frame into the Milne frame; the inverse boost $U^{-1} = \mathrm{diag}(e^{-\theta/2}, e^{\theta/2})$ removes the connection: $\gamma^0\gamma^1$ commutes with U, so $U^{-1}\Omega_\theta U = \Omega_\theta$, and $(\partial_\theta U^{-1})U = -\frac{1}{2}\gamma^0\gamma^1$, hence

$\Omega'_\theta = -\frac{1}{2}\gamma^0\gamma^1 + \frac{1}{2}\gamma^0\gamma^1 = 0$. The mixed contraction deletes the whole connection. It also violates the divergence form of Section 6.9: with $\sqrt{|g|} = \tau$, $\gamma^\tau = \gamma^0$ and $\gamma^\theta = \gamma^1/\tau$,

$$\frac{1}{2\tau}\Big(\partial_\tau(\tau\gamma^0) + \partial_\theta(\tau\cdot\tfrac{\gamma^1}{\tau})\Big) = \frac{\gamma^0}{2\tau}, \qquad \gamma^\theta\Omega_\theta = \frac{\gamma^1}{\tau}\Big(-\tfrac{1}{2}\gamma^0\gamma^1\Big) = \frac{1}{2\tau}\gamma^0\gamma^1\gamma^1 = \frac{\gamma^0}{2\tau}$$

(in the second: exchange γ^1 and γ^0 at the cost of a sign; $(\gamma^1)^2 = 1$). The correct value equals the divergence form; the mixed contraction gives 0.

The author's metric. Of the 12 components of Section 6.6 the three $(x0, x_i)$ are space-space pairs (kept), the three $(x4, x_t)$ are time-time pairs (sign reversed), and the three $(x_i, x4)$ and the three $(x0, x_t)$ are boost pairs (deleted). So, with $r = a'_4 - b'_4/(2b_4)$ and $f_t = e^{-a_4}b_4^{1/2}s$,

$$\Omega^{nb}_{x_i} = e^{a_4}s\,H\,S^{x_i\,x0}, \qquad \Omega^{nb}_{x_t} = +f_t\,r\,S^{x4\,x_t},$$

compared with $\Omega_{x_i} = e^{a_4}s(a'_4S^{x_ix4} + HS^{x_ix0})$ and $\Omega_{x_t} = -f_t(r\,S^{x4x_t} + HS^{x_tx0})$ (Section 6.7). The contraction, by the steps of Section 6.8:

$$\gamma^{x_i}\Omega^{nb}_{x_i} = \frac{\gamma^{(x_i)}}{f_i}\,f_iH\,\tfrac{1}{2}\gamma^{(x_i)}\gamma^{(x0)} = \tfrac{H}{2}\gamma^{(x0)}, \qquad \gamma^{x_t}\Omega^{nb}_{x_t} = \frac{\gamma^{(x_t)}}{f_t}\,f_t\,r\,\tfrac{1}{2}\gamma^{(x4)}\gamma^{(x_t)} = \tfrac{r}{2}\gamma^{(x4)}$$

($(\gamma^{(x_i)})^2 = 1$; and $\gamma^{(x_t)}\gamma^{(x4)}\gamma^{(x_t)} = \gamma^{(x4)}$ as in Section 6.8). Summed over the six warped directions:

$$\sum_\mu \gamma^\mu\Omega^{nb}_\mu = \tfrac{3H}{2}\gamma^{(x0)} + \tfrac{3}{2}\Big(a'_4 - \frac{b'_4}{2b_4}\Big)\gamma^{(x4)} \quad \text{instead of} \quad \sum_\mu \gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \frac{3}{4}\,\frac{b'_4}{b_4}\,\gamma^{(x4)};$$

at $b_4 = 1$, $\frac{3H}{2}\gamma^{(x0)} + \frac{3a'_4}{2}\gamma^{(x4)}$ instead of $3H\gamma^{(x0)}$. Half of the hidden term is lost, and the a'_4 terms along the time no longer cancel: with the mixed contraction the deflation would appear in this term.

The gammas are no longer covariantly constant. Replace Ω_μ by Ω^{nb}_μ in $D_\mu\gamma^\nu$:

$$D^{nb}_\mu\gamma^\nu = \partial_\mu\gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega^{nb}_\mu, \gamma^\nu] = D_\mu\gamma^\nu + [\Omega^{nb}_\mu - \Omega_\mu, \gamma^\nu] = [\Omega^{nb}_\mu - \Omega_\mu, \gamma^\nu]$$

(add and subtract $[\Omega_\mu, \gamma^\nu]$; then $D_\mu\gamma^\nu = 0$, Section 6.7). By the vector rule, $[S^{ab}, \gamma^c]$ is nonzero only when c is a or b. (The counting below is written at $b_4 = 1$; for a general b_4 replace a'_4 in the extra-time parts by $r = a'_4 - b'_4/(2b_4)$, which changes no count.) For $\mu = x1$ the difference is $\Omega^{nb}_{x1} - \Omega_{x1} = -f_1a'_4S^{x1x4}$, the deleted boost part, and

$$[\Omega^{nb}_{x1} - \Omega_{x1}, \gamma^{x1}] = -a'_4[S^{x1x4}, \gamma^{(x1)}] = -a'_4(\eta^{x4\,x1}\gamma^{(x1)} - \eta^{x1x1}\gamma^{(x4)}) = a'_4\gamma^{(x4)}$$

(the factor f_1 of the difference cancels against the $1/f_1$ of γ^{x1}; then the vector rule $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b$ with $\eta^{x4x1} = 0$ and $\eta^{x1x1} = 1$), and in the same way, with $\eta^{x4x4} = -1$,

$$[\Omega^{nb}_{x1} - \Omega_{x1}, \gamma^{x4}] = -f_1a'_4(\eta^{x4x4}\gamma^{(x1)} - \eta^{x1x4}\gamma^{(x4)}) = f_1a'_4\gamma^{(x1)}.$$

So for each 3-space direction two pairs (μ,ν) are violated. For $\mu = x5$ the difference is $2f_5 a_4' S^{x4x5} + f_5 H S^{x5x0}$ (the time-time part counted twice, because its sign was reversed, and the deleted boost part), and the same rule gives $[\ldots,\gamma^{x5}] = -2a_4'\gamma^{(x4)} + H\gamma^{(x0)}$, $[\ldots,\gamma^{x4}] = 2f_5 a_4'\gamma^{(x5)}$ and $[\ldots,\gamma^{x0}] = \tan z\, f_5 H\gamma^{(x5)}$: three violated pairs for each extra time. Altogether $3\cdot 2 + 3\cdot 3 = 15$ of the 64 pairs. Each violated matrix is a multiple of one gamma (16 nonzero entries), except $-2a_4'\gamma^{(x4)} + H\gamma^{(x0)}$, which has 32 because $\gamma^{(x4)}$ and $\gamma^{(x0)}$ have their nonzero entries in different places (the tables of Chapter 5); so there are $6\cdot 16 + 3(16+32+16) = 288$ nonzero entries. Notebook 06c finds exactly these numbers (In [13]; COMPUTED exactly by the notebook, not a Revision record).

statement	**status**	**where it is verified**
$\Omega^{nb}_\mu = \sum_{a<b} \frac{1}{2}(\eta_{aa} + \eta_{bb})\omega_{\mu ab} S^{ab} = \Omega^{ss}_\mu - \Omega^{tt}_\mu$	PROVED (above)	Notebook 06c, In [4] and In [8] (its own exact checks)
polar plane: the contractions agree; Milne wedge: $\Omega_\theta = -\frac{1}{2}\gamma^0\gamma^1$, $\Omega^{nb} = 0$	PROVED (above)	Notebook 06c, In [6]
the record does not use the mixed contraction	the record's statement	`Revision/SPEC.md`, section 3 (checked as text by Notebook 06c, In [2])
$\gamma^\mu \Omega^{nb}_\mu = \frac{3H}{2}\gamma^{(x0)} + \frac{3}{2}(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$; 15 violated pairs, 288 entries	PROVED above and COMPUTED exactly by Notebook 06c; not a Revision result (it describes the contraction the record does not use)	Notebook 06c, In [10] and In [13]

6.24 Why only the value $3H$ is right

Two facts single out the correct value $3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ ($3H\gamma^{(x0)}$ at $b_4 = 1$) among all candidates.

The divergence form. Section 6.9 showed that the correct contraction equals $\frac{1}{2\sqrt{|g|}}\sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)$, a quantity built from the volume factor and the vielbein alone. The mixed contraction, $\frac{3H}{2}\gamma^{(x0)} + \frac{3}{2}(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$, does not equal it.

The hidden-direction operator. For fields that depend on x_0 only, the part of the Dirac operator along the hidden direction is $\tan z\,\gamma^{(x0)}\partial_0 + c\,\gamma^{(x0)}$, where c is the coefficient of $\gamma^{(x0)}$ in the contraction ($c = 3H$ for the correct one, $c = \frac{3}{2}H$ for the mixed one). Write $A_c q = \tan z\,\partial_0 q + c\,q$ for a function $q(x_0)$. An operator A is called **antisymmetric for the weight** $w(x_0)$ when $\int w\,p\,(Aq)\,dx_0 = -\int w\,(Ap)\,q\,dx_0$ for all functions p, q, up to **boundary terms** (values at the ends of the interval). This is the property that makes iA a Hermitian operator in quantum theory (Chapter 10), and the natural weight is the volume factor $\sqrt{|g|} = b_4^{3/2}\cos z$; along the hidden direction $b_4^{3/2}$ is a constant factor, which multiplies every line below and is left out, so the weight is $\cos z$. Compute, line by line, for two functions $p(x_0)$, $q(x_0)$ (primes are derivatives by x_0 here):

$$\partial_0(\sin z\, p\, q) = 6H\cos z\; p\, q + \sin z\,(p' q + p\, q')$$

(the product rule; $\partial_0 \sin z = 6H \cos z$),

$$\cos z\,(p\,A_c q + (A_c p)\,q) = \cos z \tan z\,(p\,q' + p' q) + 2c \cos z\; p\,q = \sin z\,(p\,q' + p' q) + 2c \cos z\; p\,q$$

(insert A_c; $\cos z \tan z = \sin z$). Subtracting the first line from the second:

$$\cos z\,(p\,A_c q + (A_c p)\,q) - \partial_0(\sin z\,p\,q) = (2c - 6H)\cos z\; p\,q.$$

For $c = 3H$ the right side vanishes: integrated over x_0, $\int \cos z\,p\,A_{3H} q\,dx_0 = -\int \cos z\,(A_{3H} p)\,q\,dx_0 + [\sin z\,p\,q]$, so A_{3H} is antisymmetric for the weight $\cos z$ up to the boundary term. This is the record's formula `hidden_direction_hermiticity`. For the mixed value $c = \frac{3}{2}H$ the term $-3H \cos z\,p\,q$ remains, which is not a boundary term (it has no derivative in front), so no boundary condition can remove it. For $c = 0$ (no spin-connection term at all) the leftover would be $-6H \cos z\,p\,q$.

Scope of this argument. The boundary term $[\sin z\,p\,q]$ vanishes at the tip $z \to 0$ but not at the patch end $z = \pi/2$, where $\sin z = 1$; there a boundary condition is needed, which Chapter 14 supplies by the ASSUMED Z_2 mirror (the choice of boundary condition is the one point of this chapter that is left OPEN here). And the role of $3H$ depends on the variables: in the rescaled field χ of Section 6.18, with the proper distance y of Chapter 3 as coordinate and the weight dy, the operator ∂_y has the same antisymmetry without any H term (the record says so in the same formula). PROVED; `field-theory.json`, formula `hidden_direction_hermiticity` (written at $b_4 = 1$); `wolfram-field-theory.json`, check `good_sector_hermiticity_curved`; both scope reports, check `good_sector_hermiticity_up_to_the_brane_flux`; Notebook 06c, In [15].

6.25 Example: Notebook 06c

Notebook 06c checks Sections 6.23 and 6.24 with exact algebra, for arbitrary functions $a_4(x_4)$ and $b_4(x_4)$. It reads the author's gammas and the formulas of the records (with b_4, and at $b_4 = 1$), and checks that `Revision/SPEC.md` contains the record's statement about the mixed contraction. It defines the general formulas again, now with the MIXED spin connection, a separate lowering function and a contraction over all ordered pairs. It sorts the 28 frame pairs into their three kinds and checks the key step of the derivation for all of them; works the polar plane and the Milne wedge; computes, for the author's metric, the correct and the mixed spinor connections and their contractions direction by direction; counts where the covariant constancy of the gammas breaks; and checks the divergence form and the antisymmetry of the hidden-direction operator for two arbitrary functions. Every correct result is compared with the Revision records; the results about the mixed contraction are the notebook's own and are labelled so. It draws six figures, needs no Rust, runs in less than a minute and ends with the line ALL 27 CHECKS PASSED (notebook 06c).

6.26 How to run Notebook 06c

Step 1. What this notebook does and what it needs.

Notebook 06c (One missing metric factor: the mixed contraction of the spin connection) is the file `Revision/textbook/notebooks/06c_mixed_contraction.ipynb` of the repository Dirac_claude.

The Revision record builds the spinor connection from the spin connection with its first frame index lowered by the frame metric eta, and records that the author's Mathematica notebook contracts the mixed components instead, which lacks this metric factor. This notebook proves exactly, with sympy, what the missing factor does: it deletes the 16 boost components of every spin connection and reverses the sign of the 6 time-time components; it changes nothing in a space with a positive metric (the polar plane) and deletes the whole connection of a flat plane with one time (the Milne wedge); in the author's metric it would give gamma^mu Omega_mu = (3 H/2) gamma^(x0) + (3/2)(a4' - b4'/(2 b4)) gamma^(x4) instead of 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4), break the covariant constancy of the gammas in 15 of the 64 pairs, and spoil the antisymmetry of the hidden-direction operator that the Revision record proves for the correct value 3 H. It checks the correct results against the Revision records and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 06c_mixed_contraction.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 45 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06c_mixed_contraction.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 06c_mixed_contraction.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/06c.captions.json`
- `Revision/textbook/figures/06c_1_pair_kinds.png`
- `Revision/textbook/figures/06c_2_milne_frame_and_spin_boost.png`
- `Revision/textbook/figures/06c_3_per_direction_comparison.png`
- `Revision/textbook/figures/06c_4_contraction_heat_maps.png`
- `Revision/textbook/figures/06c_5_constancy_violation.png`
- `Revision/textbook/figures/06c_6_hermiticity_defect.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 27 CHECKS PASSED (notebook 06c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/06c_mixed_contraction.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 06c_mixed_contraction.ipynb
python -m nbconvert --execute --inplace 06c_mixed_contraction.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json, Revision/SPEC.md or a report: the notebook reads Revision records from the repository; open it inside the folder Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single downloaded notebook file is not enough).
- a cell runs for several minutes: the exact algebra of sympy is slow on old computers; the whole notebook needs less than a minute on a 2024 laptop, and up to about two minutes while other programs use the processor. Wait, or close the other programs.

6.27 Notebook 06c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/06c_mixed_contraction.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The spin connection $\omega$ carries one coordinate index and two frame indices.
The Revision record builds the spinor connection from the components with BOTH
frame indices down,

$$\Omega_\mu = \tfrac12 \sum_{a,b} \omega_{\mu ab} S^{ab}, \qquad
\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b ,$$

and it records (Revision/SPEC.md, section 3) that the author's Mathematica
notebook contracts the **mixed** components $\omega_\mu{}^a{}_b$ (first frame index
up) with $S^{ab}$ instead; that contraction lacks one factor of the frame metric
$\eta$ and is not used. This notebook shows, exactly, what the missing factor does.
We call the notebook's contraction

$$\Omega^{nb}_\mu = \tfrac12 \sum_{a,b} \omega_\mu{}^a{}_b S^{ab}$$

("nb" for notebook). The notebook

- proves that $\Omega^{nb}_\mu$ keeps the 6 space-space parts of $\Omega_\mu$,
  reverses the sign of the 6 time-time parts and DELETES the 16 boost parts;
- shows that the two contractions agree in a space whose metric is positive (the
  flat plane in polar coordinates), and that in a flat plane with one time (the
  **Milne wedge**) the notebook's contraction deletes the whole connection;
- computes, for the author's metric with $a_4(x_4)$ and $b_4(x_4)$, what the
  notebook's contraction would give: $\gamma^\mu\Omega^{nb}_\mu =
  \frac{3H}{2}\gamma^{(x0)} + \frac32(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$
  instead of the correct $3H\gamma^{(x0)} + \frac34\frac{b_4'}{b_4}\gamma^{(x4)}$
  (at $b_4 = 1$: $\frac{3H}{2}\gamma^{(x0)} + \frac{3a_4'}{2}\gamma^{(x4)}$
  instead of $3H\gamma^{(x0)}$);
- counts where it breaks the covariant constancy $D_\mu\gamma^\nu = 0$ of the
  gammas (15 of the 64 pairs $(\mu, \nu)$);
- shows the physical reason why only the value $3H$ is right: it makes the
  hidden-direction operator antisymmetric for the volume weight
  $\sqrt{|g|} = b_4^{3/2}\cos z$, as the Revision record proves (at $b_4 = 1$);
- draws six teaching plots.

Every correct result is compared with the Revision record. The results about
$\Omega^{nb}$ are computed by this notebook itself; they describe what the
notebook's contraction WOULD give, and the book uses them nowhere else.
```

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 06c (One missing metric factor: the mixed contraction of the spin connection) is the file ‘Revision/textbook/notebooks/06c_mixed_contraction.ipynb‘ of the repository Dirac_claude. The Revision record builds the spinor connection from the spin connection with its first frame index lowered by the frame metric eta, and records that the author’s Mathematica notebook contracts the mixed components instead, which lacks this metric factor. This notebook proves exactly, with sympy, what the missing factor does: it deletes the 16 boost components of every spin connection and reverses the sign of the 6 time-time components; it changes nothing in a space with a positive metric (the polar plane) and deletes the whole connection of a flat plane with one time (the Milne wedge); in the author’s metric it would give gamma^mu Omega_mu = (3 H/2) gamma^(x0) + (3/2)(a4’ - b4’/(2 b4)) gamma^(x4) instead of 3 H gamma^(x0) + (3/4)(b4’/b4) gamma^(x4), break the covariant constancy of the gammas in 15 of the 64 pairs, and spoil the antisymmetry of the hidden-direction operator that the Revision record proves for the correct value 3 H. It checks the correct results against the Revision records and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation

does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
```

```
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 06c_mixed_contraction.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 45 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the

notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 06c_mixed_contraction.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 06c_mixed_contraction.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/06c.captions.json‘
- ‘Revision/textbook/figures/06c_1_pair_kinds.png‘
- ‘Revision/textbook/figures/06c_2_milne_frame_and_spin_boost.png‘
- ‘Revision/textbook/figures/06c_3_per_direction_comparison.png‘
- ‘Revision/textbook/figures/06c_4_contraction_heat_maps.png‘
- ‘Revision/textbook/figures/06c_5_constancy_violation.png‘
- ‘Revision/textbook/figures/06c_6_hermiticity_defect.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 27 CHECKS PASSED (notebook 06c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it

again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/06c_mixed_contraction.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 06c_mixed_contraction.ipynb
python -m nbconvert --execute --inplace 06c_mixed_contraction.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for Revision/algebra/gammas.json, Revision/SPEC.md or a report: the notebook reads Revision records from the repository; open it inside the folder Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a single downloaded notebook file is not enough).
- a cell runs for several minutes: the exact algebra of sympy is slow on old computers; the whole notebook needs less than a minute on a 2024 laptop, and up to about two minutes while other programs use the processor. Wait, or close the other programs.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 06c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 06c (One missing metric factor: the mixed contraction of the spin connection)
# is the file Revision/textbook/notebooks/06c_mixed_contraction.ipynb of the repository
# Dirac_claude. The Revision record builds the spinor connection from the spin connection
# with its first frame index lowered by the frame metric eta, and records that the
# author's Mathematica notebook contracts the mixed components instead, which lacks this
# metric factor. This notebook proves exactly, with sympy, what the missing factor does:
# it deletes the 16 boost components of every spin connection and reverses the sign of
# the 6 time-time components; it changes nothing in a space with a positive metric (the
# polar plane) and deletes the whole connection of a flat plane with one time (the Milne
# wedge); in the author's metric it would give gamma^mu Omega_mu = (3 H/2) gamma^(x0) +
# (3/2)(a4' - b4'/(2 b4)) gamma^(x4) instead of 3 H gamma^(x0) + (3/4)(b4'/b4)
# gamma^(x4), break the covariant constancy of the gammas in 15 of the 64 pairs, and
# spoil the antisymmetry of the hidden-direction operator that the Revision record proves
# for the correct value 3 H. It checks the correct results against the Revision records
# and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run

#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
```

```
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

```
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 06c_mixed_contraction.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 45
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 06c_mixed_contraction.ipynb
```

```
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 06c_mixed_contraction.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/06c.captions.json
# - Revision/textbook/figures/06c_1_pair_kinds.png
# - Revision/textbook/figures/06c_2_milne_frame_and_spin_boost.png
# - Revision/textbook/figures/06c_3_per_direction_comparison.png
# - Revision/textbook/figures/06c_4_contraction_heat_maps.png
# - Revision/textbook/figures/06c_5_constancy_violation.png
# - Revision/textbook/figures/06c_6_hermiticity_defect.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 27 CHECKS PASSED (notebook 06c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/06c_mixed_contraction.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
```

```
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 06c_mixed_contraction.ipynb
#     python -m nbconvert --execute --inplace 06c_mixed_contraction.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json, Revision/SPEC.md or a report:
#   the notebook reads Revision records from the repository; open it inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository Dirac_claude (a
#   single downloaded notebook file is not enough).
# - a cell runs for several minutes: the exact algebra of sympy is slow on old computers;
#   the whole notebook needs less than a minute on a 2024 laptop, and up to about two
#   minutes while other programs use the processor. Wait, or close the other programs.
#

Text cell:

```
## 3. The words used in this notebook

- **Coordinates** $x0, \dots, x7$ with the author's names: $x0$ the **hidden
```

```
  direction**; $x1, x2, x3$ 3-space; $x4$ the time; $x5, x6, x7$ the three
  **extra times**; $z = 6Hx_0$. In Python lists they have the positions 0 to 7 in
  the same order.
- **Frame metric** $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order
  $x0, \dots, x7$: $\eta_{aa} = +1$ for a **space-like** frame direction, $-1$ for a
  **time-like** one. Because $\eta$ is diagonal with entries $\pm1$,
  $\eta_{aa}\eta_{aa} = 1$.
- **Upper and lower frame index.** The spin connection comes out of its formula
  with the first frame index UP, $\omega_\mu{}^a{}_b$: these are the **mixed
  components**. **Lowering** the index means multiplying by $\eta$:
  $\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b$ (no sum). The lowered
  components are **antisymmetric**, $\omega_{\mu ba} = -\omega_{\mu ab}$.
- $S^{ab} = \frac14[\gamma^a, \gamma^b]$: the 28 generators (one for each pair
  $a < b$); $S^{ba} = -S^{ab}$ and $S^{aa} = 0$.
- **Kinds of pairs** $\{a, b\}$ of two different frame directions:
  **space-space** (both space-like), **time-time** (both time-like) and
  **boost pair** (one space-like and one time-like). A boost pair generates a
  boost, the other two kinds generate rotations.
- **Spinor connection** $\Omega_\mu$ (correct) and $\Omega^{nb}_\mu$ (the
  notebook's contraction). $\Omega^{ss}_\mu$, $\Omega^{tt}_\mu$, $\Omega^{st}_\mu$:
  the parts of $\Omega_\mu$ that come from the space-space, time-time and boost
  pairs.
- **Defining property** of a spinor connection: $[\Omega_\mu, \gamma^a] =
  -\sum_b \omega_\mu{}^a{}_b\gamma^b$; **covariant constancy** of the curved gammas
  $\gamma^\mu = \sum_a e_a{}^\mu\gamma^a$: $D_\mu\gamma^\nu = \partial_\mu\gamma^\nu
  + \sum_\lambda\Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu, \gamma^\nu]
  = 0$.
- **Milne wedge**: the part $t > |y|$ of the flat plane with one time $t$ and one
  space direction $y$, $ds^2 = -dt^2 + dy^2$, described by $\tau =
  \sqrt{t^2 - y^2}$ and $\theta$ with $t = \tau\cosh\theta$, $y = \tau\sinh\theta$;
  its metric is $ds^2 = -d\tau^2 + \tau^2 d\theta^2$.
- **Spinor boost**: a matrix $U$ that turns spinors when the frame is boosted.
- **Antisymmetric for a weight**: an operator $A$ acting on functions of $x_0$ is
  antisymmetric for the weight $w(x_0)$ when $\int w\,p\,(Aq)\,dx_0 = -\int
  w\,(Ap)\,q\,dx_0$ for all functions $p, q$, up to boundary terms.
- **Exact** check: sympy proves that an expression is zero for ALL values of its
  symbols. **Heat map**: a picture of a matrix, one coloured square per entry.
```

Text cell:

```
## 4. The physical and mathematical situation

**The derivation, line by line.** Start from the notebook's contraction,

$$\Omega^{nb}_\mu = \tfrac12 \sum_{a,b} \omega_\mu{}^a{}_b S^{ab} .$$

Lowering is multiplication by $\eta_{aa}$, and $\eta_{aa}\eta_{aa} = 1$, so
$\omega_\mu{}^a{}_b = \eta_{aa}\,\omega_{\mu ab}$ (multiply
$\omega_{\mu ab} = \eta_{aa}\omega_\mu{}^a{}_b$ by $\eta_{aa}$):

$$\Omega^{nb}_\mu = \tfrac12 \sum_{a,b} \eta_{aa}\,\omega_{\mu ab} S^{ab} .$$

The terms with $a = b$ vanish ($S^{aa} = 0$). Every other term belongs to exactly
```

```
one unordered pair $\{a, b\}$ with $a < b$, which contributes two terms:

$$\eta_{aa}\,\omega_{\mu ab}S^{ab} + \eta_{bb}\,\omega_{\mu ba}S^{ba} =
(\eta_{aa} + \eta_{bb})\,\omega_{\mu ab}S^{ab} ,$$

because $\omega_{\mu ba}S^{ba} = (-\omega_{\mu ab})(-S^{ab}) = \omega_{\mu ab}
S^{ab}$ (both factors change sign). Hence

$$\Omega^{nb}_\mu = \sum_{a<b} \tfrac12(\eta_{aa} + \eta_{bb})\,
\omega_{\mu ab}S^{ab} ,$$

while the same steps without $\eta$ give the correct $\Omega_\mu = \sum_{a<b}
\omega_{\mu ab}S^{ab}$. The factor $\frac12(\eta_{aa} + \eta_{bb})$ is $+1$ for a
space-space pair, $-1$ for a time-time pair and $0$ for a boost pair. So

$$\Omega^{nb}_\mu = \Omega^{ss}_\mu - \Omega^{tt}_\mu, \qquad
\Omega_\mu = \Omega^{ss}_\mu + \Omega^{tt}_\mu + \Omega^{st}_\mu .$$

In a space whose metric is positive (every $\eta_{aa} = +1$) the factor is always
$+1$ and the two contractions are the same: the mistake cannot be seen in the usual
textbook examples. In signature (4,4) it deletes 16 of the 28 parts.

**Status.** The identity above is PROVED here (exact algebra). The values of
$\Omega^{nb}$ below are COMPUTED exactly by this notebook for the author's metric
and describe the contraction that the Revision record does NOT use. The correct
values ($\Omega_\mu$, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} +
\frac34(b_4'/b_4)\gamma^{(x4)}$, $D_\mu\gamma^\nu = 0$, the antisymmetry of the
hidden-direction operator) reproduce the Revision records.
```

Text cell:

```
## 5. The tools: sympy, the author's gammas and the record

The next cell imports numpy (numbers for the plots) and sympy (exact algebra),
reads the author's eight gamma matrices from `Revision/algebra/gammas.json`, checks
the 64 Clifford relations and that they are eight real 16 x 16 matrices, builds
the matrices $S^{ab}$, and defines the exact zero test `is_zero` (first a fast route
through exponential functions, then sympy's `simplify`; it never calls a nonzero
expression zero), `matrix_is_zero` and `record_passed` (does a Revision report
record a check as passed?). It reads the formulas of
`Revision/theory/field-theory.json` and checks that `Revision/SPEC.md` (section 3)
contains the statement about the notebook's contraction.

The first lines of the next cell change one setting of Jupyter: printed text is
sent to the screen when a cell has finished (or just before a figure is shown),
not every 0.2 seconds. This changes no result; it makes the printed text arrive in
the same pieces in every run, which the book's checking tool needs.
```

In [2]:

```
import sys  # the Python system module (here: the stream of printed text)
```

```
# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
import numpy as np  # decimal numbers (only for the plots)

Text cell:

The next cell defines the general formulas as Python functions. They work in any number of dimensions, for any vielbein matrix ‘e‘ (row = frame index, column = coordinate; its inverse ‘E = e.inv()‘ has ‘E[nu, b]‘ $= e_b{}^\nu$).

- ‘christoffel(g, coords)‘: $\Gamma^l{}_{mn}$, computed once for each pair $m \le n$.
- ‘mixed_spin_connection(e, Gam, coords)‘: the MIXED components $\omega_\mu{}^a{}_b = \sum_\nu e^a{}_\nu(\partial_\mu e_b{}^\nu + \sum_\lambda\Gamma^\nu{}_{\mu\lambda}e_b{}^\lambda)$, exactly as the formula gives them.
- ‘lower_first_index(mixed, eta)‘: $\omega_{\mu ab} = \eta_{aa}\, \omega_\mu{}^a{}_b$.
- ‘contract(coefficients, gens)‘: $\frac12\sum_{a,b}c_{\mu ab}\,S^{ab}$ for every μ, summed over ALL ordered pairs (a, b). (Notebook 06a summed over $a < b$ only, which is allowed for the antisymmetric lowered components; the mixed components are not antisymmetric, so here the full sum is needed.)
- ‘curved_gammas(e, gammas)‘: $\gamma^\mu = \sum_a e_a{}^\mu\gamma^a$.
- ‘generators(gammas)‘: the matrices $S^{ab} = \frac14[\gamma^a, \gamma^b]$.

## 6. The three kinds of frame pairs

The next cell computes the factor $\frac12(\eta_{aa} + \eta_{bb})$ of Section 4 for
every pair of frame directions of the author's frame metric, counts the 28 pairs
$a < b$ by kind (the expected counts are 6 space-space pairs among $x0, x1, x2,
x3$, 6 time-time pairs among $x4, x5, x6, x7$, and $4 \cdot 4 = 16$ boost pairs),
and checks the key step of the derivation as a matrix identity for all 28 pairs:
$\eta_{aa}\,w\,S^{ab} + \eta_{bb}\,(-w)\,S^{ba} = (\eta_{aa} + \eta_{bb})\,w\,S^{ab}$
for a symbol $w$ (which stands for $\omega_{\mu ab}$; $-w$ is $\omega_{\mu ba}$).
```

In [4]:

```
KIND = {1: "space-space", -1: "time-time", 0: "boost"}  # the factor and its name
factor = [[sp.Rational(ETA[a] + ETA[b], 2) for b in range(8)] for a in range(8)]
pairs = [(a, b) for a in range(8) for b in range(a + 1, 8)]  # the 28 pairs a < b
counts = {k: sum(1 for a, b in pairs if factor[a][b] == k) for k in KIND}
for k, name in KIND.items():
    report(f"number of {name} pairs (factor {k})", counts[k])
check(len(pairs) == 28 and counts == {1: 6, -1: 6, 0: 16},
      "28 pairs: 6 space-space (+1), 6 time-time (-1), 16 boost pairs (0)")
w = sp.Symbol("w")  # stands for omega_mu ab; then omega_mu ba = -w
check(all(matrix_is_zero(ETA[a] * w * S[a][b] + ETA[b] * (-w) * S[b][a]
                         - (ETA[a] + ETA[b]) * w * S[a][b]) for a, b in pairs),
      "eta_aa w S^ab + eta_bb (-w) S^ba = (eta_aa + eta_bb) w S^ab, all 28 pairs")
```

Out [4]:

```
RESULT number of space-space pairs (factor 1) = 6
RESULT number of time-time pairs (factor -1) = 6
RESULT number of boost pairs (factor 0) = 16
PASS 28 pairs: 6 space-space (+1), 6 time-time (-1), 16 boost pairs (0)
PASS eta_aa w S^ab + eta_bb (-w) S^ba = (eta_aa + eta_bb) w S^ab, all 28 pairs
```

Text cell:

```
The next cell draws the factor as an 8 x 8 grid: the square in row $a$ and column
$b$ shows what the notebook's contraction does to the part of the pair $\{a, b\}$:
green for KEPT (factor $+1$, space-space), orange for SIGN REVERSED (factor $-1$,
time-time) and gray for DELETED (factor $0$, boost pairs); the diagonal ($a = b$)
is white, because $S^{aa} = 0$. The gray squares form two rectangles: every
space-like direction paired with every time-like direction.
```

```
## 7. Two flat planes: where the mistake is invisible, and where it is total

**The polar plane** ($ds^2 = dr^2 + r^2d\varphi^2$, $\eta = \mathrm{diag}(1, 1)$,
vielbein $\mathrm{diag}(1, r)$, gammas $\sigma_1, \sigma_2$). Both frame directions
are space-like, so lowering changes nothing and the two contractions must agree;
the cell checks that both give $\Omega_\varphi = -\frac i2\sigma_3$, the result of
Notebook 06a.

**The Milne wedge** ($ds^2 = -d\tau^2 + \tau^2d\theta^2$, $\eta =
\mathrm{diag}(-1, +1)$, vielbein $\mathrm{diag}(1, \tau)$). Two REAL 2 x 2 gammas
with $(\gamma^0)^2 = -1$, $(\gamma^1)^2 = +1$, $\gamma^0\gamma^1 +
\gamma^1\gamma^0 = 0$ are $\gamma^0 = \begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}$
and $\gamma^1 = \begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$ (the cell checks the
three relations). The only Christoffel symbols are $\Gamma^\tau{}_{\theta\theta} =
\tau$ and $\Gamma^\theta{}_{\tau\theta} = 1/\tau$, and the formula gives the mixed
components $\omega_\theta{}^0{}_1 = \omega_\theta{}^1{}_0 = 1$: SYMMETRIC, as for
every boost pair. Lowered, $\omega_{\theta 01} = -1 = -\omega_{\theta 10}$. The
plane is flat, but the frame is BOOSTED by the rapidity $\theta$ as one moves
along $\theta$ (left picture of the next figure); the correct spinor connection
$\Omega_\theta = -\frac12\gamma^0\gamma^1$ records this, and equals
$-(\partial_\theta U)U^{-1}$ for the spinor boost $U(\theta) = \cosh\frac\theta2 +
\sinh\frac\theta2\,\gamma^0\gamma^1$. A change of frame by a spin transformation
$R(\theta)$ changes the spinor connection into $R\,\Omega_\theta R^{-1} -
(\partial_\theta R)R^{-1}$; with $R = U$ applied to the connection 0 of the
Cartesian frame $(t, y)$ this gives $\Omega_\theta$, so $U$ carries the Cartesian
frame into the Milne frame, and with $R = U^{-1}$ it gives $U^{-1}\Omega_\theta U -
(\partial_\theta U^{-1})U = 0$: the inverse boost $U^{-1}$ removes the connection
(the cell checks both). The notebook's contraction gives
$\Omega^{nb} = 0$: it deletes the whole connection. The cell also checks the
divergence form $\gamma^\mu\Omega_\mu = \frac{1}{2\sqrt{|g|}}\sum_\mu
\partial_\mu(\sqrt{|g|}\gamma^\mu) = \gamma^0/(2\tau)$ (here $\sqrt{|g|} = \tau$),
which the notebook's value $0$ violates.
```

Text cell:

The next cell draws the Milne wedge. On the left, in the flat plane with the space coordinate y horizontal and the time t vertical, the two curves $\tau = 1$ and $\tau = 2$ (hyperbolas $t^2 - y^2 = \tau^2$) and, at five values of θ, the frame: the unit time direction $e_{(0)} = (\sinh\theta, \cosh\theta)$ (blue) and the unit space direction $e_{(1)} = (\cosh\theta, \sinh\theta)$ (orange), in (y, t) components. Moving along θ the frame is boosted: both arrows tilt towards the light lines $t = \pm y$. On the right, the two diagonal entries of the spinor boost $U(\theta)$; since $\gamma^0\gamma^1 = \mathrm{diag}(1, -1)$ they are $e^{\theta/2}$ and $e^{-\theta/2}$, with $\cosh\frac\theta2$ and $\sinh\frac\theta2$ for comparison. Unlike the spinor rotation of Notebook 06a they are real and never come back: a boost has no full turn.

Text cell:

8. The author's metric: the correct and the notebook's spinor connection

The next cell builds the author's metric with its diagonal vielbein $f =
(\cot z,\ e^{a_4}s\ (\times 3),\ 1,\ e^{-a_4}b_4^{1/2}s\ (\times 3))$,
$s = \sin^{1/6}z$, for arbitrary functions $a_4(x_4)$ and $b_4(x_4) > 0$, computes
the Christoffel symbols, the MIXED spin connection and its lowered form, and
compares the 12 nonzero lowered components with the records (‘omega_nonzero‘ of
the record with b_4, and at $b_4 = 1$ of the record of $b_4 = 1$; the records
number the directions from 1 in the order $x0, \dots, x7$). Then it builds the
correct
Ω_μ, the notebook's Ω^{nb}_μ and the three parts
Ω^{ss}_μ, Ω^{tt}_μ, Ω^{st}_μ, and checks the identity
of Section 4, $\Omega^{nb}_\mu = \Omega^{ss}_\mu - \Omega^{tt}_\mu$, for all eight
μ. It prints, for each of the 12 lowered components, the kind of its pair and
what the notebook's contraction does to it.

## 9. What the notebook's contraction would put into the field equation

The field equation contains the 16 x 16 matrix $\gamma^\mu\Omega_\mu$ (summed over
$\mu$). The next cell computes each term $\gamma^\mu\Omega_\mu$ (no sum) for both
```

```
contractions and writes it as $\alpha_\mu\gamma^{(x4)} + \beta_\mu\gamma^{(x0)}$
(the coefficients are found with traces, as in Notebook 06a:
$\alpha_\mu = -\mathrm{tr}(M\gamma^{(x4)})/16$ and $\beta_\mu =
\mathrm{tr}(M\gamma^{(x0)})/16$, and the cell checks that nothing else is left).
By hand: $\gamma^{x1}\Omega^{nb}_{x1} = \frac{1}{f_1}\gamma^{(x1)}\cdot f_1 H\cdot
\frac12\gamma^{(x1)}\gamma^{(x0)} = \frac H2\gamma^{(x0)}$ (because
$(\gamma^{(x1)})^2 = 1$), and $\gamma^{x5}\Omega^{nb}_{x5} =
\frac{1}{f_5}\gamma^{(x5)}\cdot f_5 r_t\cdot\frac12\gamma^{(x4)}\gamma^{(x5)} =
-\frac{r_t}{2}\gamma^{(x4)}(\gamma^{(x5)})^2 = \frac{r_t}{2}\gamma^{(x4)}$ with
$r_t = a_4' - b_4'/(2b_4)$ (because $\gamma^{(x5)}$ anticommutes with
$\gamma^{(x4)}$ and $(\gamma^{(x5)})^2 = -1$). Summed:

$$\gamma^\mu\Omega^{nb}_\mu = \tfrac{3H}{2}\gamma^{(x0)} + \tfrac32\big(a_4' -
\tfrac{b_4'}{2b_4}\big)\gamma^{(x4)} \quad\text{instead of}\quad
\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \tfrac34\tfrac{b_4'}{b_4}\gamma^{(x4)} .$$

Half of the hidden term is lost, and the $a_4'$ terms along the time no longer
cancel: with the wrong contraction the deflation would appear in this term. The
cell compares the correct total with the records (‘gammaOmega_total‘ with $b_4$,
and at $b_4 = 1$).
```

```
## 10. The gammas are no longer covariantly constant
```

```
With the correct $\Omega_\mu$ the curved gammas are covariantly constant,
$D_\mu\gamma^\nu = 0$ for all 64 pairs $(\mu, \nu)$ (Notebook 06a; the Revision
record). Replace $\Omega_\mu$ by $\Omega^{nb}_\mu$:

$$D^{nb}_\mu\gamma^\nu = \partial_\mu\gamma^\nu +
\sum_\lambda\Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega^{nb}_\mu, \gamma^\nu]
= D_\mu\gamma^\nu + [\Omega^{nb}_\mu - \Omega_\mu, \gamma^\nu] =
[\Omega^{nb}_\mu - \Omega_\mu, \gamma^\nu] .$$

The first step adds and subtracts $[\Omega_\mu, \gamma^\nu]$; the second uses
$D_\mu\gamma^\nu = 0$. The next cell computes both versions for all 64 pairs,
checks the correct one against the record, checks this identity, counts the pairs
$(\mu, \nu)$ in which $D^{nb}_\mu\gamma^\nu$ is not zero and the number of its
nonzero entries (exact counts of this notebook), and checks that the defining
property $[\Omega_\mu, \gamma^a] = -\sum_b\omega_\mu{}^a{}_b\gamma^b$ fails for
$\Omega^{nb}$.
```

Text cell:

```
## 11. Why only the value $3H$ is right: the half-density term
```

```
Two facts of the Revision record single out the correct value.

**The divergence form.** Because $\{\gamma^\mu, \Omega_\mu\} = 0$ for each $\mu$
and $D_\mu\gamma^\nu = 0$, the correct contraction equals
$\frac{1}{2\sqrt{|g|}}\sum_\mu\partial_\mu(\sqrt{|g|}\,\gamma^\mu)$ (Notebook 06a),
a quantity built from the metric and the vielbein alone. The cell checks that it
equals the correct value and not the notebook's.

**The hidden-direction operator.** For fields that depend on $x_0$ only, the
derivative part of the field equation along $x0$ is the operator $A_c q =
\tan z\,\partial_{x0}q + c\,q$, where $c$ is the coefficient of $\gamma^{(x0)}$ in
$\gamma^\mu\Omega_\mu$. The volume weight is $\sqrt{|g|} = b_4^{3/2}\cos z$; along
the hidden direction the factor $b_4^{3/2}$ is a constant, which multiplies both
sides below and is left out, so the weight is $\cos z$ (the record's formula is
written at $b_4 = 1$). Compute, with the product rule and
$\partial_{x0}\sin z = 6H\cos z$:

$$\partial_{x0}(\sin z\,p\,q) = 6H\cos z\,p\,q + \sin z\,(p'q + p\,q') ,$$

$$\cos z\,\big(p\,A_cq + (A_cp)\,q\big) = \sin z\,(p\,q' + p'q) + 2c\cos z\,p\,q$$

(using $\cos z\tan z = \sin z$). Subtracting,

$$\cos z\,\big(p\,A_cq + (A_cp)\,q\big) - \partial_{x0}(\sin z\,p\,q) =
(2c - 6H)\cos z\,p\,q .$$

For $c = 3H$ the right side vanishes: integrated over $x_0$, $\int\cos z\,p\,A_cq
= -\int\cos z\,(A_cp)\,q$ plus a boundary term, so $A_{3H}$ is antisymmetric for
the weight $\cos z$; this is the record's formula 'hidden_direction_hermiticity',
and it is what makes the operator of the quantum theory Hermitian (up to boundary
conditions). For the notebook's $c = \frac{3H}{2}$ the term $-3H\cos z\,p\,q$
remains: no boundary term can absorb it. The next cell checks all of this exactly
for two arbitrary functions $p(x_0)$, $q(x_0)$.
```

## 13. What this notebook showed

- The notebook's contraction $\Omega^{nb}_\mu = \frac12\sum_{a,b}
  \omega_\mu{}^a{}_b S^{ab}$ of the MIXED components equals $\sum_{a<b}
  \frac12(\eta_{aa} + \eta_{bb})\,\omega_{\mu ab}S^{ab}$: it keeps the 6
```

```
  space-space parts, reverses the sign of the 6 time-time parts and deletes the 16
  boost parts of every spin connection (PROVED, exact).
- With a positive metric (the polar plane) the two contractions agree, so the
  mistake cannot show up there; in the Milne wedge, a flat plane with one time, the
  frame is boosted along $\theta$ and the notebook's contraction deletes the whole
  connection $\Omega_\theta = -\frac12\gamma^0\gamma^1$ (PROVED).
- For the author's metric the correct spin connection reproduces the records
  (`omega_nonzero`, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} +
  \frac34(b_4'/b_4)\gamma^{(x4)}$, $D_\mu\gamma^\nu = 0$), while the notebook's
  contraction would give $\gamma^\mu\Omega^{nb}_\mu = \frac{3H}{2}\gamma^{(x0)} +
  \frac32(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$ (at $b_4 = 1$:
  $\frac{3H}{2}\gamma^{(x0)} + \frac{3a_4'}{2}\gamma^{(x4)}$) and would break the
  covariant constancy of the gammas in 15 of the 64 pairs $(\mu, \nu)$, with 288
  nonzero entries (COMPUTED exactly here; not a Revision result).
- Only the correct value $3H$ equals the divergence form
  $\frac{1}{2\sqrt{|g|}}\partial_\mu(\sqrt{|g|}\gamma^\mu)$ and makes the
  hidden-direction operator $\tan z\,\partial_{x0} + 3H$ antisymmetric for the
  volume weight $\cos z$ (times the constant $b_4^{3/2}$ along $x0$) up to the
  boundary term $\partial_{x0}(\sin z\,p\,q)$
  (reproduces the record's formula `hidden_direction_hermiticity`); the
  notebook's value leaves the term $-3H\cos z\,p\,q$.
- This is why the Revision record, and this book, use the lowered components
  $\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b$ in the spinor connection.
```

6.28 Line-by-line walk-through of Notebook 06c

The notebook has 17 code cells, In [1] to In [17]; this section explains every line of every one of them. A line `...` in a quoted figure cell stands for the remaining lines of a long caption, printed in full in Section 6.27.

In [1], the set-up cell. Its comment lines are the run instructions of Section 6.26. Its code is the set-up code of Notebook 06a explained at the beginning of Section 6.14, with the single difference

```
NOTEBOOK_ID = "06c"  # this notebook: chapter 06, example c
```

It prints one line, Set-up of notebook 06c complete: repository folder found, helpers defined.

In [2], the tools and the record.

```
import sys  # the Python system module (here: the stream of printed text)

# Jupyter sends printed text to the screen in pieces, about every 0.2 seconds.  The
# book's checking tool reads each PASS line together with its "reproduces" line, so
# the pieces must be the same in every run: send the printed text of a cell in one
# piece when the cell ends (or just before a figure), at the latest after 600 s.
if hasattr(sys.stdout, "flush_interval"):  # true inside Jupyter only
    sys.stdout.flush_interval = 600.0
```

The setting of the output channel explained in Section 6.14 (Notebook 06a, In [2]).

```
import numpy as np  # decimal numbers (only for the plots)
import sympy as sp  # exact algebra and calculus with symbols
```

numpy for the plots and sympy for the exact algebra.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
NAMES = fixture["coordinates"]  # ["x0", ..., "x7"]
ETA = fixture["eta"]  # +1 space-like, -1 time-like
gamma = [sp.Matrix(rows) for rows in fixture["gamma"]]  # gamma[a] = gamma^(xa)
I16, Z16 = sp.eye(16), sp.zeros(16, 16)  # identity and zero matrix
```

The record of the gammas is read as in Notebook 06a: the names, the signs of η, the eight exact matrices, the identity and the zero matrix.

```
check(all(gamma[a] * gamma[b] + gamma[b] * gamma[a]
          == (2 * ETA[a] if a == b else 0) * I16
          for a in range(8) for b in range(8)),
      "the 64 Clifford relations of the author's gammas",
      record="Revision/theory/reports/python-field-theory.json, "
             "check clifford_relations")
check(len(gamma) == 8 and all(M.shape == (16, 16) for M in gamma)
      and all(entry.is_real for M in gamma for entry in M),
      "the eight gammas are 16 x 16 matrices with real entries",
      record="Revision/theory/reports/python-field-theory.json, check gammas_real")
```

The two checks of Notebook 06a, In [2]: the 64 Clifford relations, and eight real 16×16 matrices, each with its record.

```
S = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
     for a in range(8)]  # S[a][b] = S^ab
```

The 64 generators S^{ab}.

```
def is_zero(expr):
    """True when expr is exactly zero for all values of its symbols."""
    expr = sp.sympify(expr)
    if expr == 0:

statement = "contraction of the mixed omega_mu^a_b, which lacks a metric factor"
check(statement in spec_text,
      "Revision/SPEC.md section 3 records the missing metric factor")
```

The notebook checks that the statement on which it is built is in the record. `" ".join(text.split())` replaces every run of blanks and line breaks by one blank (`split()` cuts the text at all blanks and line breaks, `" ".join` glues the pieces with single blanks), so that a sentence that the file breaks across two lines is found as one line. The check requires `Revision/SPEC.md` to contain the words "contraction of the mixed omega_mu^a_b, which lacks a metric factor" (`in` tests whether one text occurs inside another). The cell prints three PASS lines.

In [3], the general formulas, now with the mixed connection (Sections 6.4 and 6.23).

```
def christoffel(g, coords):
    """Gam[l][m][n] = (1/2) sum_r g^lr (d_m g_rn + d_n g_rm - d_r g_mn)."""
    n = len(coords)
    g_inv = g.inv()  # the inverse metric
    Gam = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for l in range(n):
        for m in range(n):
            for k in range(m, n):  # Gamma^l_mk = Gamma^l_km: compute it once
                value = sum(g_inv[l, r] * (sp.diff(g[r, k], coords[m])
```

```
                                        + sp.diff(g[r, m], coords[k])
                                        - sp.diff(g[m, k], coords[r]))
                                for r in range(n) if g_inv[l, r] != 0) / 2
                Gam[l][m][k] = Gam[l][k][m] = sp.simplify(value)
    return Gam
```

The Christoffel symbols, as in Notebook 06b, In [3].

```
def mixed_spin_connection(e, Gam, coords):
    """mixed[mu][a][b] = omega_mu^a_b (first frame index up)."""
    n = len(coords)
    E = e.inv()  # E[nu, b] = e_b^nu, the inverse vielbein
    mixed = [[[sp.Integer(0)] * n for _ in range(n)] for _ in range(n)]
    for mu in range(n):
        for a in range(n):
            for b in range(n):
                value = 0
                for nu in range(n):
                    if e[a, nu] == 0:
                        continue  # this term is zero
                    value += e[a, nu] * (sp.diff(E[nu, b], coords[mu]) + sum(
                        Gam[nu][mu][lam] * E[lam, b] for lam in range(n)))
                mixed[mu][a][b] = sp.simplify(value)
    return mixed
```

`mixed_spin_connection` is the spin connection of Notebook 06a, In [4], without the last step: it returns the MIXED components $\omega_\mu{}^a{}_b$ exactly as the formula of Section 6.4 gives them, without multiplying by η_{aa}.

```
def lower_first_index(mixed, eta):
    """omega[mu][a][b] = eta_aa omega_mu^a_b (eta is diagonal)."""
    n = len(mixed)
    return [[[eta[a] * mixed[mu][a][b] for b in range(n)] for a in range(n)]
            for mu in range(n)]
```

`lower_first_index` does the lowering separately: $\omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b$ for all μ, a, b.

```
def contract(coefficients, gens):
    """(1/2) sum over ALL ordered pairs (a, b) of coefficients[mu][a][b] S^ab."""
    n = len(coefficients)
    size = gens[0][0].shape[0]  # 16 for the author's gammas, 2 in a plane
    return [sum((coefficients[mu][a][b] * gens[a][b] / 2 for a in range(n)
                 for b in range(n) if coefficients[mu][a][b] != 0),
                sp.zeros(size, size)) for mu in range(n)]
```

`contract(coefficients, gens)` is $\frac{1}{2}\sum_{a,b} c_{\mu ab} S^{ab}$ for every μ, summed over ALL ordered pairs (a, b) (the term is skipped when the coefficient is zero). Notebook 06a summed over $a < b$ only, which is allowed for the antisymmetric lowered components; the mixed components are not antisymmetric, so here the full sum is needed, and the same function serves both contractions.

```
def curved_gammas(e, gammas):
    """gamma^mu = sum_a e_a^mu gamma^a for every coordinate mu."""
    E = e.inv()
    n = len(gammas)
    return [sum((E[mu, a] * gammas[a] for a in range(n)),
                sp.zeros(*gammas[0].shape)) for mu in range(n)]
```

The curved gammas, as before.

```
def generators(gammas):
    """S[a][b] = (1/4)(gamma^a gamma^b - gamma^b gamma^a)."""
    n = len(gammas)
    return [[(gammas[a] * gammas[b] - gammas[b] * gammas[a]) / 4 for b in range(n)]
            for a in range(n)]
```

`generators(gammas)` builds the matrices $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b]$ for any list of gammas; it is used for the 2×2 gammas of the two planes.

```
say("defined: christoffel, mixed_spin_connection, lower_first_index, contract, "
    "curved_gammas, generators")
```

One output line names the six functions.

In [4], the three kinds of frame pairs.

```
KIND = {1: "space-space", -1: "time-time", 0: "boost"}  # the factor and its name
factor = [[sp.Rational(ETA[a] + ETA[b], 2) for b in range(8)] for a in range(8)]
pairs = [(a, b) for a in range(8) for b in range(a + 1, 8)]  # the 28 pairs a < b
counts = {k: sum(1 for a, b in pairs if factor[a][b] == k) for k in KIND}
for k, name in KIND.items():
    report(f"number of {name} pairs (factor {k})", counts[k])
```

`KIND` names the three values of the factor. `factor[a][b]` is $\frac{1}{2}(\eta_{aa} + \eta_{bb})$ as an exact fraction (`sp.Rational(n, 2)`); `pairs` lists the 28 pairs $a < b$, and `counts` counts the pairs of each kind (`sum(1 for ... if ...)` counts the cases in which the condition holds). Three RESULT lines print 6, 6 and 16.

```
check(len(pairs) == 28 and counts == {1: 6, -1: 6, 0: 16},
      "28 pairs: 6 space-space (+1), 6 time-time (-1), 16 boost pairs (0)")
```

The check of the counts: 28 pairs, 6 with the factor $+1$, 6 with -1, 16 with 0.

```
w = sp.Symbol("w")  # stands for omega_mu ab; then omega_mu ba = -w
check(all(matrix_is_zero(ETA[a] * w * S[a][b] + ETA[b] * (-w) * S[b][a]
                         - (ETA[a] + ETA[b]) * w * S[a][b]) for a, b in pairs),
      "eta_aa w S^ab + eta_bb (-w) S^ba = (eta_aa + eta_bb) w S^ab, all 28 pairs")
```

The key step of the derivation of Section 6.23 as a matrix identity, for all 28 pairs: with a symbol w standing for $\omega_{\mu ab}$ (so that $\omega_{\mu ba} = -w$), $\eta_{aa}\, w\, S^{ab} + \eta_{bb}(-w) S^{ba} = (\eta_{aa} + \eta_{bb})\, w\, S^{ab}$. The cell prints three RESULT lines and two PASS lines.

In [5], figure 1.

```
from matplotlib.colors import ListedColormap  # a colour map with a few colours
```

`ListedColormap` makes a colour map out of a short list of colours: the number 0 gets the first colour, 1 the second, and so on.

```
grid = np.full((8, 8), 3)  # 3 = the diagonal (white)
for a in range(8):
    for b in range(8):
        if a != b:
            grid[a, b] = {1: 0, -1: 1, 0: 2}[int(factor[a][b])]  # colour number
```

`grid` is an 8×8 array filled with 3 (white, for the diagonal); off the diagonal the factor $+1$, -1, 0 is translated into the colour numbers 0, 1, 2 by the small dictionary `{1: 0, -1: 1, 0: 2}`.

```
colours = ListedColormap(["tab:green", "tab:orange", "lightgray", "white"])
fig, ax = plt.subplots(figsize=(6.4, 5.6))
ax.imshow(grid, cmap=colours, vmin=-0.5, vmax=3.5)
```

The four colours green, orange, light gray and white; `imshow` draws the grid with them (the limits -0.5 and 3.5 put each whole number in the middle of its colour).

```
for a in range(8):
    for b in range(8):
        if a != b:
            ax.text(b, a, f"{int(factor[a][b]):+d}" if factor[a][b] else "0",
                    ha="center", va="center", fontsize=9)
```

Each off-diagonal square gets its factor written in it, `+1`, `-1` or `0` (`:+d` writes a whole number with its sign).

```
ax.set_xticks(range(8), NAMES)
ax.set_yticks(range(8), NAMES)
ax.set_xlabel("frame direction $b$")
ax.set_ylabel("frame direction $a$")
ax.set_title("Factor $(\\eta_{aa} + \\eta_{bb})/2$ of the notebook's contraction")
ax.grid(False)
```

Labels and title; no grid lines.

```
for colour, label in (("tab:green", "kept: space-space (+1)"),
                      ("tab:orange", "sign reversed: time-time (-1)"),
                      ("lightgray", "deleted: boost pair (0)")):
    ax.plot([], [], "s", color=colour, markersize=9, label=label)  # legend only
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.13), ncol=2, fontsize=8)
```

Three empty plots with square markers (`"s"`) only make the legend entries, and the legend is placed below the picture in two columns (`bbox_to_anchor` gives its position relative to the panel).

```
save_figure(fig, "pair_kinds",
            "What the missing metric factor does to each pair of frame directions "
            ...
            "reversed and 16 deleted.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.1 shows. Green squares (+1, kept) fill the pairs among $x0, x1, x2, x3$, orange squares (-1, sign reversed) the pairs among $x4, x5, x6, x7$, and gray squares (0, deleted) form two 4×4 rectangles: every space-like direction paired with every time-like direction. Counting the upper half: 6 green, 6 orange, 16 gray. The mixed contraction deletes more than half of the spin connection.

In [6], the two flat planes (Section 6.23).

```
r, phi = sp.symbols("r phi", positive=True)  # the polar plane
sigma1 = sp.Matrix([[0, 1], [1, 0]])
sigma2 = sp.Matrix([[0, -sp.I], [sp.I, 0]])
sigma3 = sp.Matrix([[1, 0], [0, -1]])
polar_S = generators([sigma1, sigma2])
polar_e = sp.diag(1, r)  # unit radial and unit angular direction
polar_mixed = mixed_spin_connection(polar_e, christoffel(sp.diag(1, r**2), [r, phi]),
                                    [r, phi])
polar_Omega = contract(lower_first_index(polar_mixed, [1, 1]), polar_S)
polar_Omega_nb = contract(polar_mixed, polar_S)
check(polar_Omega == polar_Omega_nb and polar_Omega[1] == -sp.I / 2 * sigma3,
      "polar plane (eta = +1, +1): both contractions give Omega_phi = -(i/2) sigma3")
```

The polar plane: the Pauli matrices, their generators, the vielbein $\mathrm{diag}(1, r)$, the mixed connection of the metric $\mathrm{diag}(1, r^2)$, and both contractions, the correct one from the lowered components (with $\eta = (1, 1)$) and the mixed one. The check requires them to be equal and $\Omega_\varphi = -\frac{i}{2}\sigma_3$, as in Notebook 06a.

```
tau = sp.Symbol("tau", positive=True)  # the Milne wedge: tau > 0
theta = sp.Symbol("theta", real=True)  # the rapidity coordinate
g0 = sp.Matrix([[0, 1], [-1, 0]])  # real, squares to -1 (the time direction)
g1 = sp.Matrix([[0, 1], [1, 0]])  # real, squares to +1 (the space direction)
I2, Z2 = sp.eye(2), sp.zeros(2, 2)
check(g0 * g0 == -I2 and g1 * g1 == I2 and g0 * g1 + g1 * g0 == Z2,
      "Milne: real gammas with (g0)^2 = -1, (g1)^2 = +1, g0 g1 + g1 g0 = 0")
```

The Milne wedge: the positive symbol τ, the real symbol θ (the rapidity can be negative), the two real gammas of Section 6.23 and the check of their three relations.

```
milne_S = generators([g0, g1])
milne_e = sp.diag(1, tau)  # unit time direction and unit space direction
```

```
milne_Gam = christoffel(sp.diag(-1, tau**2), [tau, theta])
milne_mixed = mixed_spin_connection(milne_e, milne_Gam, [tau, theta])
milne_lowered = lower_first_index(milne_mixed, [-1, 1])
```

The generators, the vielbein $\mathrm{diag}(1, \tau)$, the Christoffel symbols of the metric $\mathrm{diag}(-1, \tau^2)$, the mixed connection, and its lowered form with $\eta = (-1, +1)$.

```
say(f"Gamma^tau_thetatheta = {milne_Gam[0][1][1]}, "
    f"Gamma^theta_tautheta = {milne_Gam[1][0][1]}")
say(f"mixed: omega_theta^0_1 = {milne_mixed[1][0][1]}, "
    f"omega_theta^1_0 = {milne_mixed[1][1][0]}")
say(f"lowered: omega_theta01 = {milne_lowered[1][0][1]}, "
    f"omega_theta10 = {milne_lowered[1][1][0]}")
check(milne_mixed[1][0][1] == 1 and milne_mixed[1][1][0] == 1
      and milne_lowered[1][0][1] == -1 and milne_lowered[1][1][0] == 1,
      "Milne: mixed components symmetric (1, 1), lowered antisymmetric (-1, +1)")
```

Three output lines print $\Gamma^{\tau}{}_{\theta\theta} = \tau$, $\Gamma^{\theta}{}_{\tau\theta} = 1/\tau$, the mixed components $1, 1$ and the lowered ones $-1, 1$; the check requires exactly these: mixed symmetric, lowered antisymmetric.

```
milne_Omega = contract(milne_lowered, milne_S)
milne_Omega_nb = contract(milne_mixed, milne_S)
X2 = g0 * g1  # gamma^0 gamma^1, the boost generator of the plane (X2^2 = 1)
check(milne_Omega[0] == Z2 and milne_Omega[1] == -X2 / 2
      and milne_Omega_nb == [Z2, Z2],
      "Milne: Omega_theta = -(1/2) g0 g1, but the notebook's contraction gives 0")
```

The two contractions. `X2` is $\gamma^0\gamma^1$, the boost generator of the plane times 2. The check requires $\Omega_\tau = 0$, $\Omega_\theta = -\frac{1}{2}\gamma^0\gamma^1$, and the mixed contraction to be zero in both directions (a list of two zero matrices).

```
U = sp.cosh(theta / 2) * I2 + sp.sinh(theta / 2) * X2  # the spinor boost
removed = U.inv() * milne_Omega[1] * U - U.inv().diff(theta) * U  # frame change U^-1
check(matrix_is_zero(-U.diff(theta) * U.inv() - milne_Omega[1])
      and matrix_is_zero(removed),
      "Milne: Omega_theta = -(dU/dtheta) U^-1 for the spinor boost U; U^-1 removes it")
```

The spinor boost $U(\theta) = \cosh\frac{\theta}{2} + \sinh\frac{\theta}{2}\,\gamma^0\gamma^1$. `removed` is the rule $R\,\Omega_\theta R^{-1} - (\partial_\theta R)R^{-1}$ of a change of frame (Section 6.15) with $R = U^{-1}$, whose inverse is U. The check requires $\Omega_\theta = -(\partial_\theta U)U^{-1}$ (the same rule with $R = U$ applied to the connection 0 of the frame of t and y: U carries that frame into the Milne frame) and `removed` to be zero (the inverse boost U^{-1} removes the connection), as worked by hand in Section 6.23.

```
milne_gup = curved_gammas(milne_e, [g0, g1])  # gamma^tau = g0, gamma^theta = g1/tau
slash_milne = (milne_gup[0] * milne_Omega[0] + milne_gup[1] * milne_Omega[1])
divergence_milne = ((tau * milne_gup[0]).diff(tau)
                    + (tau * milne_gup[1]).diff(theta)) / (2 * tau)
check(matrix_is_zero(slash_milne - g0 / (2 * tau))
      and matrix_is_zero(divergence_milne - slash_milne),
      "Milne: gamma^mu Omega_mu = g0/(2 tau) = the divergence form (notebook: 0)")
```

The curved gammas $\gamma^\tau = \gamma^0$, $\gamma^\theta = \gamma^1/\tau$, the correct contraction, and the divergence form with $\sqrt{|g|} = \tau$; the check requires both to be $\gamma^0/(2\tau)$, which the mixed value 0 violates. The cell prints three lines and six PASS lines.

In [7], figure 2.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.8))
curve = np.linspace(-1.3, 1.3, 200)  # values of theta for the hyperbolas
for radius in (1.0, 2.0):
    ax_left.plot(radius * np.sinh(curve), radius * np.cosh(curve), ":",
                 color="gray", linewidth=1.0)
    for rapidity in (-1.0, -0.5, 0.0, 0.5, 1.0):
        py, pt = radius * np.sinh(rapidity), radius * np.cosh(rapidity)  # the point
        ax_left.quiver(py, pt, np.sinh(rapidity), np.cosh(rapidity),
                       color="tab:blue", angles="xy", scale_units="xy", scale=2.5,
                       width=0.006)  # e_(0), the unit time direction
        ax_left.quiver(py, pt, np.cosh(rapidity), np.sinh(rapidity),
                       color="tab:orange", angles="xy", scale_units="xy",
                       scale=2.5, width=0.006)  # e_(1), the unit space direction
```

Two panels. On the left, for $\tau = 1$ and $\tau = 2$, the dotted curve $(y, t) = (\tau \sinh\theta, \tau\cosh\theta)$ for 200 values of θ, and at five rapidities $\theta = -1, -0.5, 0, 0.5, 1$ the frame: the unit time direction $(\sinh\theta, \cosh\theta)$ in blue and the unit space direction $(\cosh\theta, \sinh\theta)$ in orange, both in (y, t) components, drawn with `quiver` as in Notebook 06a.

```
light = np.linspace(0.0, 3.6, 2)
ax_left.plot(light, light, "--", color="black", linewidth=0.8)  # t = y
ax_left.plot(-light, light, "--", color="black", linewidth=0.8,
             label="light lines $t = \\pm y$")  # t = -y
ax_left.plot([], [], color="tab:blue", label="unit time direction $e_{(0)}$")
ax_left.plot([], [], color="tab:orange", label="unit space direction $e_{(1)}$")
```

The two dashed light lines $t = y$ and $t = -y$ from the origin, and two empty plots for the legend.

```
ax_left.set_xlim(-3.6, 3.6)
ax_left.set_ylim(0.0, 4.6)
ax_left.set_aspect("equal")
ax_left.set_xlabel("space coordinate $y = \\tau\\sinh\\theta$")
ax_left.set_ylabel("time $t = \\tau\\cosh\\theta$")
ax_left.set_title("The Milne frame is boosted along $\\theta$")
ax_left.legend(loc="upper center", fontsize=7)
```

Axis ranges, equal units, labels, title and legend.

```
rapidities = np.linspace(-4.0, 4.0, 401)
ax_right.plot(rapidities, np.exp(rapidities / 2),
              label="$U_{11} = e^{\\theta/2}$")
ax_right.plot(rapidities, np.exp(-rapidities / 2), "--",
              label="$U_{22} = e^{-\\theta/2}$")
```

```
ax_right.plot(rapidities, np.cosh(rapidities / 2), ":", color="black",
              label="$\\cosh(\\theta/2)$")
ax_right.plot(rapidities, np.sinh(rapidities / 2), "-.", color="gray",
              label="$\\sinh(\\theta/2)$")
ax_right.set_xlabel("rapidity $\\theta$")
ax_right.set_ylabel("entry of the spinor boost (pure number)")
ax_right.set_title("A spinor boost is real and grows")
ax_right.legend(fontsize=8)
```

The right panel: for θ from -4 to 4 the two diagonal entries of the spinor boost, $e^{\theta/2}$ and $e^{-\theta/2}$ (because $\gamma^0\gamma^1 = \mathrm{diag}(1,-1)$, $U = \mathrm{diag}(\cosh\frac{\theta}{2} + \sinh\frac{\theta}{2}, \cosh\frac{\theta}{2} - \sinh\frac{\theta}{2})$), and for comparison $\cosh\frac{\theta}{2}$ and $\sinh\frac{\theta}{2}$.

```
save_figure(fig, "milne_frame_and_spin_boost",
            "The Milne wedge, a flat plane with one time in which the notebook's "
            ...
            "$\\theta$: real and unbounded, unlike a spinor rotation.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.2 shows. On the left, the frame at $\theta = 0$ is upright (time up, space to the right); moving along θ the blue and orange arrows tilt symmetrically towards the dashed light lines, as in figure 1 of Notebook 06b: the frame is boosted along θ, and the correct spin connection $\omega_{\theta 01} = -1$ records this rate, although the plane is flat. On the right, the entries $e^{\pm\theta/2}$ of the spinor boost $U(\theta)$, which carries the frame of t and y into the Milne frame (its inverse removes the connection), grow or fall without bound and never return, unlike the spinor rotation of figure 1 of Notebook 06a, which came back after 4π. The mixed contraction would delete this whole connection.

In [8], the author's metric: the correct and the mixed spinor connection (Section 6.23).

```
from sympy.parsing.mathematica import parse_mathematica  # reads Wolfram notation
```

The reader of Wolfram notation.

```
x = sp.symbols("x0:8", real=True)  # x[0] = x0, ..., x[4] = x4, ..., x[7] = x7
x0, x4 = x[0], x[4]  # the hidden direction and the time
H = sp.Symbol("H", positive=True)  # the author's constant H > 0
a4 = sp.Function("a4")(x4)  # any function of the time
b4 = sp.Function("b4", positive=True)(x4)  # any positive function of the time
a4p, b4p = sp.Derivative(a4, x4), sp.Derivative(b4, x4)  # a4' and b4'
rate_t = a4p - b4p / (2 * b4)  # the rate of the extra times, a4' - b4'/(2 b4)
z = 6 * H * x0  # the hidden angle
s = sp.sin(z) ** sp.Rational(1, 6)
f = ([sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
     + [sp.exp(-a4) * sp.sqrt(b4) * s] * 3)  # f_0, ..., f_7
g = sp.diag(*[ETA[a] * f[a] ** 2 for a in range(8)])  # the author's metric
e = sp.diag(*f)  # the diagonal vielbein
```

The symbols, the factors, the metric with b_4, the diagonal vielbein and the helper `at_b4_1`, as in Notebook 06a, In [7]; `a4p` and `b4p` are short names for a_4' and b_4', and `rate_t` is the rate $a_4' - b_4'/(2b_4)$ of the extra times.

```
Gam = christoffel(g, x)
mixed = mixed_spin_connection(e, Gam, x)  # omega_mu^a_b
omega = lower_first_index(mixed, ETA)  # omega_mu ab
```

The Christoffel symbols, the mixed connection $\omega_\mu{}^a{}_b$ and the lowered connection $\omega_{\mu ab}$.

```
names = {sp.Symbol("H"): H, sp.Symbol("x0"): x0, sp.Symbol("x4"): x4,
         sp.Symbol("a4"): a4, sp.Symbol("b4"): b4, sp.Symbol("a4p"): a4p,
         sp.Symbol("b4p"): b4p}

def record_omega(formulas):
    text = formulas["omega_nonzero"]
    for long_form, short_form in (("Derivative[1][a4][x4]", "a4p"),
                                  ("Derivative[1][b4][x4]", "b4p"),
                                  ("a4[x4]", "a4"), ("b4[x4]", "b4")):
        text = text.replace(long_form, short_form)
    return {(int(m) - 1, int(a) - 1, int(b) - 1): v.subs(names, simultaneous=True)
            for m, a, b, v in parse_mathematica(text)}

omega_record = record_omega(FORMULAS_B4)
omega_record_1 = record_omega(FORMULAS)
```

`record_omega(formulas)` reads the list `omega_nonzero` of a record: its Wolfram names for a_4', b_4', a_4 and b_4 are shortened, the text is parsed, the plain symbols are replaced by the notebook's, and the directions are renumbered (the records number them from 1 in the order $x0, \ldots, x7$, Python from 0). Both records are read, the one with b_4 and the one of $b_4 = 1$.

```
nonzero = {(mu, a, b): omega[mu][a][b] for mu in range(8) for a, b in pairs
           if omega[mu][a][b] != 0}
check(set(nonzero) == set(omega_record) == set(omega_record_1)
      and all(is_zero(nonzero[k] - omega_record[k])
              and is_zero(at_b4_1(nonzero[k]) - omega_record_1[k]) for k in nonzero),
      "the 12 nonzero lowered components omega_mu ab equal the records (with b4, and "
      "at b4 = 1)",
      record=f"{THEORY_B4_FILE} and {THEORY_FILE}, formula omega_nonzero")
```

The nonzero lowered components with $a < b$, compared with both records: the same twelve keys, and the same values as the record with b_4 and, at $b_4 = 1$, as the record of $b_4 = 1$.

```
ACTION = {1: "kept", -1: "sign reversed", 0: "deleted"}
for (mu, a, b) in sorted(nonzero):
    k = int(factor[a][b])
    say(f"omega_{NAMES[mu]},{NAMES[a]}{NAMES[b]}: {KIND[k]} pair, {ACTION[k]}")
```

For each of the twelve components (sorted by their keys) one line is printed with the kind of its pair and what the mixed contraction does to it, for example `omega_x1,x1x4:  boost pair, deleted` and `omega_x5,x4x5:  time-time pair, sign reversed`.

```
Omega = contract(omega, S)  # the correct spinor connection
Omega_nb = contract(mixed, S)  # the notebook's contraction
```

The correct spinor connection is the contraction of the lowered components, the mixed one the contraction of the mixed components; the same function `contract` makes both.

```
def part(kind):
    """The part of Omega that comes from the pairs of one kind."""
    return contract([[[omega[mu][a][b] if factor[a][b] == kind else 0
                       for b in range(8)] for a in range(8)] for mu in range(8)], S)
```

`part(kind)` keeps only the lowered components whose pair is of the given kind (all others are set to 0) and contracts them: the parts Ω^{ss}, Ω^{tt} and Ω^{st}.

```
Omega_ss, Omega_tt, Omega_st = part(1), part(-1), part(0)
check(all(matrix_is_zero(Omega[mu] - Omega_ss[mu] - Omega_tt[mu] - Omega_st[mu])
          and matrix_is_zero(Omega_nb[mu] - Omega_ss[mu] + Omega_tt[mu])
          for mu in range(8)),
      "Omega^nb_mu = Omega^ss_mu - Omega^tt_mu for all eight mu (boosts deleted)")
```

The check of the identity of Section 6.23 for all eight μ: Ω_μ is the sum of its three parts, and $\Omega^{nb}_\mu = \Omega^{ss}_\mu - \Omega^{tt}_\mu$. The cell prints twelve lines and two PASS lines.

In [9], the closed forms.

```
closed_ok = True
for i in (1, 2, 3):  # the 3-space directions x1, x2, x3
    closed_ok = closed_ok and matrix_is_zero(
        Omega_nb[i] - sp.exp(a4) * s * H * S[i][0])  # pair (x0, xi) kept
    closed_ok = closed_ok and matrix_is_zero(
        Omega[i] - sp.exp(a4) * s * (a4p * S[i][4] + H * S[i][0]))
f_t = sp.exp(-a4) * sp.sqrt(b4) * s  # the factor of the extra times
for t in (5, 6, 7):  # the extra times x5, x6, x7
    closed_ok = closed_ok and matrix_is_zero(
        Omega_nb[t] - f_t * rate_t * S[4][t])  # pair (x4, xt) reversed
    closed_ok = closed_ok and matrix_is_zero(
        Omega[t] + f_t * (rate_t * S[4][t] + H * S[t][0]))
check(closed_ok, "the closed forms of Omega_mu and Omega^nb_mu for x1 ... x3, "
      "x5 ... x7")
```

For the three 3-space directions (positions 1, 2, 3) the check requires $\Omega^{nb}_{x_i} = e^{a_4} s\, H\, S^{x_i x0}$ and $\Omega_{x_i} = e^{a_4} s\, (a'_4 S^{x_i x4} + H S^{x_i x0})$ (`S[i][0]` is $S^{x_i x0}$, `S[i][4]` is $S^{x_i x4}$); for the three extra times (positions 5, 6, 7), with `f_t` $= e^{-a_4} b_4^{1/2} s$ and $r =$ `rate_t`, $\Omega^{nb}_{x_t} = f_t\, r\, S^{x4 x_t}$ and $\Omega_{x_t} = -f_t\, (r\, S^{x4 x_t} + H S^{x_t x0})$. One PASS line.

In [10], the two contractions direction by direction.

```
gup = curved_gammas(e, gamma)  # gamma^mu = gamma^a / f_a for mu = a
```

The curved gammas.

```
def split(M):
    """(alpha, beta, rest is zero) for M = alpha gamma^(x4) + beta gamma^(x0)."""
    alpha = sp.simplify(-(M * gamma[4]).trace() / 16)  # coefficient of gamma^(x4)
    beta = sp.simplify((M * gamma[0]).trace() / 16)  # coefficient of gamma^(x0)
    return alpha, beta, matrix_is_zero(M - alpha * gamma[4] - beta * gamma[0])
```

`split(M)` returns the coefficients α of $\gamma^{(x4)}$ and β of $\gamma^{(x0)}$, found with traces as in Section 6.8, and whether nothing else is left.

```
correct_terms = [split(gup[mu] * Omega[mu]) for mu in range(8)]
notebook_terms = [split(gup[mu] * Omega_nb[mu]) for mu in range(8)]
for mu in range(8):
    say(f"{NAMES[mu]}: correct ({correct_terms[mu][0]}, {correct_terms[mu][1]}), "
        f"notebook ({notebook_terms[mu][0]}, {notebook_terms[mu][1]})")
```

Both contractions are split for each direction and printed side by side, eight lines such as `x5: correct (-Derivative(a4(x4), x4)/2, H/2), notebook (Derivative(a4(x4), x4)/2, 0)`.

```
want_nb = [(0, 0)] + [(0, H / 2)] * 3 + [(0, 0)] + [(rate_t / 2, 0)] * 3
check(all(term[2] for term in correct_terms + notebook_terms)
      and all(is_zero(notebook_terms[mu][0] - want_nb[mu][0])
              and is_zero(notebook_terms[mu][1] - want_nb[mu][1]) for mu in range(8)),
      "notebook's terms: (H/2) gamma^(x0) for x1, x2, x3; ((a' - b4'/(2 b4))/2) "
      "gamma^(x4) for x5, x6, x7")
```

The check requires every split to leave nothing over and the mixed terms to be $(0,0)$ for $x0$, $(0,\frac{H}{2})$ for $x1, x2, x3$, $(0,0)$ for $x4$ and $(\frac{1}{2}(a_4' - \frac{b_4'}{2b_4}),0)$ for $x5, x6, x7$, as derived in Section 6.23.

```
slash = sum((gup[mu] * Omega[mu] for mu in range(8)), Z16)
slash_nb = sum((gup[mu] * Omega_nb[mu] for mu in range(8)), Z16)

def record_total(formulas):
    text = formulas["gammaOmega_total"].replace(chr(34), "")  # gamma[x0], gamma[x4]
    for long_form, short_form in (("Derivative[1][b4][x4]", "b4p"),
                                  ("b4[x4]", "b4"), ("gamma[x0]", "G0"),
                                  ("gamma[x4]", "G4")):
        text = text.replace(long_form, short_form)
    total = parse_mathematica(text).subs(names, simultaneous=True)
    G0, G4 = sp.Symbol("G0"), sp.Symbol("G4")
    return total.coeff(G0) * gamma[0] + total.coeff(G4) * gamma[4]

check(matrix_is_zero(slash - record_total(FORMULAS_B4))
      and matrix_is_zero(at_b4_1(slash) - record_total(FORMULAS))
      and record_passed(REPORT_PY, "gamma_mu_Omega_mu_equals_3H_gamma_x0"),
      "correct: gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4); "
      "3 H gamma^(x0) at b4 = 1",
      record=f"{THEORY_B4_FILE} and {THEORY_FILE}, formula gammaOmega_total")
```

The two totals. `sum(..., Z16)` adds the eight matrices $\gamma^\mu\Omega_\mu$, one for each direction μ, starting from the zero matrix `Z16`: `slash` is the correct total $\sum_\mu \gamma^\mu\Omega_\mu$ and `slash_nb` the total of the notebook's contraction. `record_total(formulas)` turns the formula `gammaOmega_total` of a record into a matrix. In the record with b_4 it is the text `3*H*gamma["x0"] + (3*gamma["x4"]*Derivative[1][b4][x4])/(4*b4[x4])`, in the record of $b_4 = 1$ the text `3*H*gamma["x0"]`. `chr(34)` is the double-quote character (34 is its number in the ASCII table), and `.replace(chr(34), "")` removes every double quote, as the comment says. (The code avoids writing the quoted name `gamma["x0"]` inside a Python string: that would need a string in single quotes, and the book prints straight single quotes in code as curly ones, which Python does not accept.) The loop then replaces the Wolfram names of b_4' and b_4 by short names and `gamma[x0]`, `gamma[x4]` by the plain names `G0`, `G4`, and `parse_mathematica` (In [8]) reads the text as a sympy expression; `.subs` replaces its plain symbols by the notebook's (its `H` is a new symbol that knows nothing about its sign). `.coeff(G0)` and `.coeff(G4)` pick out the factors of the two names, and the function returns that combination of $\gamma^{(x0)}$ and $\gamma^{(x4)}$. The check requires the correct total to be the record's with b_4, and at $b_4 = 1$ the record's $3H\gamma^{(x0)}$, and, through `record_passed`, the sympy report `python-field-theory.json` (the name `REPORT_PY` of In [2]) to record its check `gamma_mu_Omega_mu_equals_3H_gamma_x0` as passed. Its second printed line names the record formulas it reproduces.

```
report("notebook: coefficient of gamma^(x0)", sum(t[1] for t in notebook_terms))
report("notebook: coefficient of gamma^(x4)",
       sp.simplify(sum(t[0] for t in notebook_terms)))
check(matrix_is_zero(slash_nb - 3 * H / 2 * gamma[0] - 3 * rate_t / 2 * gamma[4]),
      "notebook: gamma^mu Omega^nb_mu = (3H/2) gamma^(x0) + (3/2)(a4' - b4'/(2 b4)) "
      "gamma^(x4)")
```

Two RESULT lines print the mixed coefficients $\frac{3H}{2}$ and $\frac{3}{2}a_4' - \frac{3}{4}b_4'/b_4$, and the last check requires the mixed total to be exactly $\frac{3H}{2}\gamma^{(x0)} + \frac{3}{2}(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$. The cell prints eight lines, three PASS lines and two RESULT lines.

In [11], figure 3.

```
positions = np.arange(8)
width = 0.38  # the width of one bar; two bars side by side per direction
alpha_c = [float(sp.simplify(at_b4_1(t[0]) / a4p)) for t in correct_terms]  # b4 = 1
alpha_n = [float(sp.simplify(at_b4_1(t[0]) / a4p)) for t in notebook_terms]
beta_c = [float(sp.simplify(t[1] / H)) for t in correct_terms]  # units of H
beta_n = [float(sp.simplify(t[1] / H)) for t in notebook_terms]
```

The places of the bars, the width of one bar (two bars side by side for each direction), and the coefficients in units of a_4' (on the background $b_4 = 1$, `at_b4_1`) and of H for both contractions.

```
fig, (ax_left, ax_right) = plt.subplots(1, 2, figsize=(10.0, 4.2), sharey=True)
ax_left.bar(positions - width / 2, alpha_c, width, color="tab:blue",
            label=f"correct (total {sum(alpha_c):g})")
ax_left.bar(positions + width / 2, alpha_n, width, color="lightskyblue",
            label=f"notebook (total {sum(alpha_n):g})")
ax_right.bar(positions - width / 2, beta_c, width, color="tab:red",
             label=f"correct (total {sum(beta_c):g})")
ax_right.bar(positions + width / 2, beta_n, width, color="lightsalmon",
             label=f"notebook (total {sum(beta_n):g})")
```

Two bar charts with a common vertical axis: the correct bars dark (blue on the left, red on the right) and shifted half a bar to the left, the mixed bars light and shifted to the right; each label shows the total.

```
ax_left.set_title("coefficient of $\\gamma^{(x4)}$, units of $a_4'$")
ax_right.set_title("coefficient of $\\gamma^{(x0)}$, units of $H$")
for ax in (ax_left, ax_right):
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xticks(positions, NAMES)
    ax.set_xlabel("direction $\\mu$ of the term $\\gamma^\\mu\\Omega_\\mu$")
    ax.set_ylim(-0.8, 0.8)
    ax.legend(fontsize=8, loc="lower left")
ax_left.set_ylabel("coefficient")
```

Titles, a zero line, the direction names, the axis range from -0.8 to 0.8 and the legends.

```
save_figure(fig, "per_direction_comparison",
            "The eight terms $\\gamma^\\mu\\Omega_\\mu$ (no sum) of the author's "
            ...
            "to $3$, the notebook keeps only three of them, total $3/2$.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.3 shows. On the left, the dark bars are $+\frac{1}{2}$ for $x1, x2, x3$ and $-\frac{1}{2}$ for $x5, x6, x7$ and cancel (total 0), while the light bars are zero for 3-space and $+\frac{1}{2}$ for the extra times (total $\frac{3}{2}$): the deleted boost parts of 3-space and the reversed time-time parts of the extra times destroy the cancellation. On the right, the six dark bars of height $\frac{1}{2}$ add to 3, while the mixed contraction keeps only the three of 3-space (total $\frac{3}{2}$): the boost parts $(x_t, x0)$ of the extra times are deleted.

In [12], figure 4.

```
SAMPLE = {H: 1, x0: sp.pi / 24}  # H = 1 and z = 6 H x0 = pi/4

def at_sample(expr):
    """The decimal value of expr at H = 1, z = pi/4, a4 = 1/2, a4' = 1/2, b4 = 1."""
    expr = at_b4_1(expr).subs(a4p, sp.Rational(1, 2))  # a4' first, then a4
    expr = expr.subs(a4, sp.Rational(1, 2))
    return float(sp.N(expr.subs(SAMPLE)))

def sample_table(matrix):
    """The matrix as an array of decimal numbers at the sample point."""
    return np.array([[at_sample(v) for v in row] for row in matrix.tolist()])
```

The sample point of Notebook 06a on the background $b_4 = 1$ ($H = 1$, $z = \pi/4$, $a_4 = a_4' = \frac{1}{2}$, $b_4 = 1$; here no a_4'' occurs), with $b_4 = 1$ put in first (`at_b4_1`) and then a_4' before a_4; and `sample_table`, as in Notebook 06b.

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.2))
for ax, (title, matrix) in zip(axes, (
```

```
        ("correct: $\\gamma^\\mu\\Omega_\\mu$", slash),
        ("notebook: $\\gamma^\\mu\\Omega^{nb}_\\mu$", slash_nb))):
    image = ax.imshow(sample_table(matrix), cmap="RdBu_r", vmin=-3.2, vmax=3.2)
    ax.set_title(title)
    ax.set_xticks([])
    ax.set_yticks([])
    ax.grid(False)
fig.colorbar(image, ax=axes, shrink=0.85, label="entry value")
```

Two heat maps on one common colour scale from -3.2 to 3.2: the correct total and the mixed total.

```
save_figure(fig, "contraction_heat_maps",
            "The total $\\gamma^\\mu\\Omega_\\mu$ as a 16 x 16 heat map at the sample "
            ...
            "deflation.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.4 shows. On the left, the correct $3H\gamma^{(x0)}$: the value 3 (dark red) on two diagonal lines in the off-diagonal blocks, nothing else. On the right, the same two lines with half the value, 1.5, and in addition the pattern of $\gamma^{(x4)}$ with entries ± 0.75: with the mixed contraction the field equation would contain a term proportional to the rate a_4' of the deflation.

In [13], the covariant constancy (Section 6.23).

```
violation = {}  # (mu, nu) -> D^nb_mu gamma^nu, for the pairs where it is not zero
correct_ok, identity_ok, entries = True, True, 0
for mu in range(8):
    for nu in range(8):
        common = gup[nu].diff(x[mu]) + sum((Gam[nu][mu][lam] * gup[lam]
                                            for lam in range(8)), Z16)
        D_correct = common + Omega[mu] * gup[nu] - gup[nu] * Omega[mu]
        D_nb = common + Omega_nb[mu] * gup[nu] - gup[nu] * Omega_nb[mu]
        difference = Omega_nb[mu] - Omega[mu]
        correct_ok = correct_ok and matrix_is_zero(D_correct)
        identity_ok = identity_ok and matrix_is_zero(
            D_nb - (difference * gup[nu] - gup[nu] * difference))
        nonzero_entries = sum(1 for v in D_nb if not is_zero(v))
        if nonzero_entries:
            violation[(mu, nu)] = D_nb
            entries += nonzero_entries
```

For all 64 pairs (μ, ν): `common` is the part $\partial_\mu\gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda$ that both versions share; `D_correct` adds $[\Omega_\mu, \gamma^\nu]$ and `D_nb` adds $[\Omega^{nb}_\mu, \gamma^\nu]$. Three things are recorded: whether `D_correct` is zero, whether `D_nb` equals $[\Omega^{nb}_\mu - \Omega_\mu, \gamma^\nu]$, and how many entries of `D_nb` are not zero; the nonzero matrices are kept in the dictionary `violation`, and their nonzero entries are counted in `entries`.

```
check(correct_ok and record_passed(REPORT_WL_B4, "gamma_covariantly_constant"),
      "correct: D_mu gamma^nu = 0 for all 64 pairs",
      record=f"{REPORT_WL_B4}, check gamma_covariantly_constant")
check(identity_ok, "D^nb_mu gamma^nu = [Omega^nb_mu - Omega_mu, gamma^nu], all 64")
```

Two checks: the correct version vanishes for all 64 pairs (with the record's check), and the identity of Section 6.23 holds for all 64.

```
report("pairs (mu, nu) with D^nb_mu gamma^nu not zero", len(violation))
report("nonzero entries of these 16 x 16 matrices", entries)
say("violated pairs: " + ", ".join(f"({NAMES[m]},{NAMES[n]})"
                                   for m, n in sorted(violation)))
check(len(violation) == 15 and entries == 288,
      "notebook: D^nb_mu gamma^nu is not zero in 15 of 64 pairs (288 entries)")
```

Two RESULT lines print 15 pairs and 288 entries, one line lists the violated pairs, `(x0,x0), (x0,x3), ..., (x6,x7)`, and the check requires exactly 15 and 288, the numbers derived in Section 6.23.

```
failures = [(mu, a) for mu in range(8) for a in range(8) if not matrix_is_zero(
    Omega_nb[mu] * gamma[a] - gamma[a] * Omega_nb[mu]
    + sum((mixed[mu][a][b] * gamma[b] for b in range(8)), Z16))]
report("pairs (mu, a) where the defining property fails for Omega^nb", len(failures))
check(len(failures) > 0 and all(matrix_is_zero(
    Omega[mu] * gamma[a] - gamma[a] * Omega[mu]
    + sum((mixed[mu][a][b] * gamma[b] for b in range(8)), Z16))
    for mu in range(8) for a in range(8)),
      "the defining property holds for Omega and fails for Omega^nb",
      record=f"{REPORT_WL}, check S_rotates_gamma_with_omega")
```

`failures` lists the pairs (μ, a) in which the defining property $[\Omega, \gamma^a] = -\sum_b \omega_\mu{}^a{}_b \gamma^b$ fails for Ω^{nb}; a RESULT line prints their number, 15. The check requires at least one failure for Ω^{nb} and none for the correct Ω (all 64 pairs), with the WolframScript report's check. The cell prints three PASS lines, three RESULT lines and the list.

In [14], figure 5.

```
size = np.zeros((8, 8))
for (mu, nu), matrix in violation.items():
    size[mu, nu] = np.abs(sample_table(matrix)).max()  # the largest entry
```

For each violated pair, the largest absolute entry of $D^{nb}_\mu \gamma^\nu$ at the sample point.

```
fig, ax = plt.subplots(figsize=(6.4, 5.4))
image = ax.imshow(size, cmap="Oranges", vmin=0.0)
for (mu, nu) in violation:
    dark = size[mu, nu] > 0.6 * size.max()  # white digits on dark squares
    ax.text(nu, mu, f"{size[mu, nu]:.2f}", ha="center", va="center", fontsize=7,
            color="white" if dark else "black")
ax.set_xticks(range(8), NAMES)
ax.set_yticks(range(8), NAMES)
ax.set_xlabel("upper index $\\nu$ of $\\gamma^\\nu$")
ax.set_ylabel("derivative index $\\mu$")
ax.set_title("Largest entry of $D^{nb}_\\mu\\gamma^\\nu$ at the sample point")
ax.grid(False)
fig.colorbar(image, ax=ax, shrink=0.8, label="largest absolute entry")
```

A heat map in shades of orange with the values written into the squares (white digits on the dark squares), the derivative index μ as rows and the upper index ν as columns, and a colour bar.

```
save_figure(fig, "constancy_violation",
            "Where the notebook's contraction breaks the covariant constancy of the "
            ...
            "connection all 64 matrices vanish exactly.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.5 shows. Only the rows of the six warped directions have coloured squares; the rows $x4$ and $x0$ are white because $\Omega_{x4} = \Omega_{x0} = 0$ in both versions. Each 3-space row has two squares: $(x_i, x_i) = 0.50$, which is $a'_4 = \frac{1}{2}$, and $(x_i, x4) = 0.78$, which is $f_1 a'_4 = 1.556 \cdot \frac{1}{2}$. Each extra-time row has three: $(x_t, x_t) = 1.00$, the larger of $2a'_4 = 1$ and $H = 1$, and $(x_t, x4) = (x_t, x0) = 0.57$, which is $2f_5 a'_4 = f_5 H = 0.572$ at $z = \pi/4$ ($\tan z = 1$). All values are those derived in Section 6.23. With the correct connection the whole grid would be white.

In [15], why only $3H$ is right (Section 6.24).

```
sqrt_g = b4 ** sp.Rational(3, 2) * sp.cos(z)  # sqrt|det g| of the author's metric
divergence = sum(((sqrt_g * gup[mu]).diff(x[mu]) for mu in range(8)), Z16) / (2 * sqrt_g)
check(matrix_is_zero(divergence - slash) and not matrix_is_zero(divergence - slash_nb),
      "the divergence form equals the correct contraction, not the notebook's",
      record=f"{REPORT_WL_B4}, check gammaOmega_divergence_form")
```

The divergence form with $\sqrt{|g|} = b_4^{3/2} \cos z$; the check requires it to equal the correct contraction and NOT the mixed one (`not matrix_is_zero(...)`), and the WolframScript report with b_4 to record the divergence form as passed.

```
p = sp.Function("p")(x0)  # two arbitrary functions of x0
q = sp.Function("q")(x0)
c = sp.Symbol("c", real=True)  # the coefficient of gamma^(x0)
```

Two arbitrary functions $p(x_0)$, $q(x_0)$ and a real symbol c for the coefficient of $\gamma^{(x0)}$.

```
def A(u):
    """The hidden-direction operator A_c u = tan z du/dx0 + c u."""
    return sp.tan(z) * u.diff(x0) + c * u
```

The hidden-direction operator $A_c u = \tan z \, \partial_0 u + c\, u$.

```
leftover = sp.cos(z) * (p * A(q) + A(p) * q) - sp.diff(sp.sin(z) * p * q, x0)
check(is_zero(leftover - (2 * c - 6 * H) * sp.cos(z) * p * q),
      "cos z (p A_c q + (A_c p) q) - d0(sin z p q) = (2c - 6H) cos z p q")
```

`leftover` is $\cos z\,(p\,A_c q + (A_c p)\,q) - \partial_0(\sin z\, p\, q)$, and the check requires it to be $(2c - 6H)\cos z\, p\, q$ exactly, for every c and all functions p, q.

```
record_text = FORMULAS["hidden_direction_hermiticity"]
check(is_zero(leftover.subs(c, 3 * H)) and "Tan[z] d0 + 3 H" in record_text
      and "= d0 (Sin[z] p q)" in record_text,
      "c = 3H: A_c is antisymmetric for the weight cos z up to d0(sin z p q)",
      record=f"{THEORY_FILE}, formula hidden_direction_hermiticity")
```

For $c = 3H$ the leftover vanishes; and the record's text of `hidden_direction_hermiticity` must contain the operator `Tan[z] d0 + 3 H` and the boundary term `= d0 (Sin[z] p q)`.

```
check(is_zero(leftover.subs(c, 3 * H / 2) + 3 * H * sp.cos(z) * p * q),
      "c = 3H/2 (notebook): the leftover -3 H cos z p q remains")
```

For the mixed value $c = \frac{3}{2}H$ the leftover is $-3H\cos z\,p\,q$. The cell prints four PASS lines, two with records.

In [16], figure 6.

```
zz = np.linspace(0.0, np.pi / 2, 300)  # the hidden angle z from 0 to pi/2
fig, ax = plt.subplots(figsize=(7.0, 4.2))
ax.axhline(0.0, color="gray", linewidth=0.6, zorder=1)  # the zero line, underneath
for value, style, width, label in ((3.0, "-", 2.5, "correct $c = 3H$"),
                                   (1.5, "--", 1.5, "notebook $c = 3H/2$"),
                                   (0.0, ":", 1.5, "no connection term, $c = 0$")):
    ax.plot(zz, (2 * value - 6) * np.cos(zz), style, linewidth=width, label=label,
            zorder=3)  # drawn above the zero line
ax.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax.set_ylabel("leftover coefficient $(2c/H - 6)\\cos z$")
ax.set_title("Only $c = 3H$ makes the hidden operator antisymmetric")
ax.legend(fontsize=8)
```

300 values of z from 0 to $\pi/2$. A thin gray zero line is drawn first (`zorder=1` puts it underneath), then the leftover coefficient $(2c/H - 6)\cos z$ for $c = 3H$ (thick solid), $c = \frac{3}{2}H$ (dashed) and $c = 0$ (dotted), above it (`zorder=3`).

```
save_figure(fig, "hermiticity_defect",
            "The term that spoils the antisymmetry of the hidden-direction operator "
            ...
            "term; the solid line lies on the zero line.")
```

The figure is saved; the cell prints its file name.

What Figure 06c.6 shows. The thick solid line of the correct value $c = 3H$ lies on the zero line for every z: nothing is left but the boundary term. The dashed line of the mixed value starts at -3 at the tip and rises to 0 at the patch end, and the dotted line of $c = 0$ starts at -6. Only the correct coefficient makes the hidden-direction operator antisymmetric for the volume weight $\cos z$.

In [17], the last checks.

```
cited = {
    REPORT_PY: ["clifford_relations", "gammas_real", "vielbein_postulate",
```

```
                "spin_connection_antisymmetric", "covariant_constancy_D_mu_gamma_nu",

}
count = sum(len(names) for names in cited.values())
check(all(record_passed(path, name) for path, names in cited.items()
          for name in names),
      f"the {count} cited record checks are recorded as passed")
```

The 17 cited checks, 7 of the sympy field-theory report and 6 of the WolframScript one (both of $b_4 = 1$) and 4 of the WolframScript report with b_4, each stating a correct result reproduced here; the check requires all of them to be recorded as passed.

```
expected = [f"06c_{k}_{name}.png" for k, name in enumerate([
    "pair_kinds", "milne_frame_and_spin_boost", "per_direction_comparison",
    "contraction_heat_maps", "constancy_violation", "hermiticity_defect"], 1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected),
      "all six figure files exist")
all_checks_passed()
```

The six figure files must exist, and the last line is printed: ALL 27 CHECKS PASSED (notebook 06c).

6.29 The exact scope of the statement that gravity enters the field equations

The author asked that the field equations of both fields "always possess non-zero contributions from gravity (through the canonical spin-connection, unless we are in flat 4+4 spacetime)". This chapter has proved several exact statements, and they must be read together. The Revision record states the conclusion in its own correction (in `Revision/README.md`): the non-triviality tests [1] and [2] hold in a qualified sense. Here is that sense, statement by statement.

What is true in the diagonal vielbein. $\sum_\mu \gamma^\mu D_\mu\Psi - \sum_\mu \gamma^\mu \partial_\mu\Psi = \big(3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}\big)\Psi$, which is nonzero for every $H > 0$, every function a_4 and every field that is not zero, except at times where $|b_4'/b_4| = 4H$; for a constant b_4, as on the backgrounds $b_4 = 1$, it is $3H\gamma^{(x0)}\Psi$ and never zero for a nonzero field (Sections 6.8 and 6.10). The record's non-triviality checks are made at $b_4 = 1$; the exception for a changing b_4 is recorded by the check `gravity_term_square_b4` of `python-field-theory-b4.json`.

Where the term comes from. The Lagrangian of Chapter 7 contains the symmetric kinetic term $\frac{1}{2}\sum_\mu \big(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi\big)$. Insert $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$ (Section 6.7):

$$\tfrac{1}{2}\sum_\mu \big(\bar\Psi\gamma^\mu\partial_\mu\Psi - (\partial_\mu\bar\Psi)\gamma^\mu\Psi\big) + \tfrac{1}{2}\sum_\mu \bar\Psi\big(\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu\big)\Psi$$

(multiply out; the two Ω terms collect into one). By Fact 1 of Section 6.9 the last bracket vanishes for each μ separately. **In the author's metric and the diagonal vielbein the canonical**

spin connection drops out of the Lagrangian completely. The term $3H\gamma^{(x0)}$ comes back in the field equation from the volume factor and the vielbein: vary the connection-free term $\sqrt{|g|}\,\frac{1}{2}\sum_\mu(\bar\Psi\gamma^\mu\partial_\mu\Psi-(\partial_\mu\bar\Psi)\gamma^\mu\Psi)$ with respect to $\bar\Psi$ by the Euler-Lagrange rule of Chapter 7 (the derivative by $\bar\Psi$ minus $\sum_\mu\partial_\mu$ of the derivative by $\partial_\mu\bar\Psi$, the two treated as independent):

$$\tfrac{1}{2}\sqrt{|g|}\sum_\mu\gamma^\mu\partial_\mu\Psi-\sum_\mu\partial_\mu\Big(-\tfrac{1}{2}\sqrt{|g|}\,\gamma^\mu\Psi\Big)=\sqrt{|g|}\sum_\mu\gamma^\mu\partial_\mu\Psi+\tfrac{1}{2}\sum_\mu\partial_\mu(\sqrt{|g|}\,\gamma^\mu)\Psi$$

(the product rule on the second term). Divided by $\sqrt{|g|}$ the last term is the divergence form of Section 6.9, $\sum_\mu\gamma^\mu\Omega_\mu\Psi=\big(3H\gamma^{(x0)}+\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}\big)\Psi$. The record calls it the **half-density term** (volume and vielbein divergence). Chapter 7 carries out the variation for both statistics with every sign. Records (at $b_4=1$; Fact 1 and the divergence form hold for every b_4, Section 6.9): both scope reports, check `connection_free_lagrangian_same_equations`; `wolfram-field-theory.json`, checks `L_spin_connection_drops_out_G` and `L_spin_connection_drops_out_C`.

What depends on choices. The value of $\gamma^\mu\Omega_\mu$ belongs to the diagonal vielbein: in the frame boosted with the rate $\beta=6H$ the contraction vanishes identically for a constant b_4 (Section 6.16). It also belongs to the field variable Ψ: for $\chi=\sin^{1/2}(z)\,b_4^{3/4}\,\Psi$ the term is absent for $U=0$ and becomes the coupling $\lambda S[\chi]/(b_4^{3/2}\sin z)$ for $U=\frac{\lambda}{2}S^2$ (Section 6.18). It contains no trace of the deflation a_4 (Section 6.8).

What does not depend on any choice.

- The spin connection vanishes in no frame: its curvature is the Riemann curvature, $F_{\mu\nu}=\frac{1}{2}R_{ab\mu\nu}S^{ab}$, and $R^{x0}{}_{x0}=-6H^2\neq0$ for every $H>0$ and every b_4 (Section 6.17). The metric is curved for every member of the family.
- The vielbein enters every derivative term of the field equation through the factors $e^{-a_4}s^{-1}$, $e^{a_4}b_4^{-1/2}s^{-1}$ and $\tan z$; this is where the inflation of 3-space and the exponential deflation of the extra times act on the fields (Section 6.10).
- The spin connection reaches the energy-momentum tensor of the fields: for a configuration that depends on the time only, the off-diagonal kinetic term $K^{x4}{}_{x1}$ has the connection part $\frac{1}{2}e^{a_4}s\,H\,\bar\Phi\gamma^{(x4)}\gamma^{(x1)}\gamma^{(x0)}\Phi$, which is not identically zero (both scope reports, check `spin_connection_in_the_energy_momentum_tensor`, at $b_4=1$; Chapter 9 treats the energy-momentum tensor).

In one sentence. Gravity enters the field equations of both fields in every frame and every choice of field variables, through the vielbein factors and through a spin connection whose curvature cannot be removed; the particular matrix $3H\gamma^{(x0)}+\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ ($3H\gamma^{(x0)}$ on the backgrounds $b_4=1$) is the form this takes in the diagonal vielbein with the variable Ψ, and it is a property of these choices, not of the physics alone. Chapter 8 returns to this scope and adds the question of well-posedness.

statement	status	where it is verified
the connection drops out of the symmetric Lagrangian; the field equations are those of the connection-free symmetric Lagrangian, with the half-density term	PROVED	both scope reports, check `connection_free_lagrangian_same_equations`; `wolfram-field-theory.json`, checks `L_spin_connection_drops_out_G`, `L_spin_connection_drops_out_C`
the value of $\gamma^\mu\Omega_\mu$ is frame-dependent and removable by a rescaling	PROVED	Sections 6.16 and 6.18 (Notebook 06b; scope reports at $b_4 = 1$)
the spin connection vanishes in no frame; the metric is never flat	PROVED	Section 6.17
the connection enters the energy-momentum tensor	PROVED	both scope reports, check `spin_connection_in_the_energy_momentum_tensor`

6.30 What we proved, what we computed, what we assumed

PROVED (exact; derived in this chapter line by line, confirmed by exact checks of the notebooks named, and, where stated, by the Revision record):

- The diagonal vielbein $f = (\cot z,\ e^{a_4}s\ (\times 3),\ 1,\ e^{-a_4}b_4^{1/2}s\ (\times 3))$ reproduces the author's metric; $\sqrt{|\det g|} = b_4^{3/2}\cos z$ depends on the time only through b_4; the curved gammas obey $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}$; every Λe with $\Lambda^T\eta\Lambda = \eta$ is another vielbein (Section 6.2; Notebook 06a, In [7]; `metric-b4.json`, keys `metricDiagonal`, `sqrtAbsDetG`; at $b_4 = 1$ `field-theory.json`, formulas `metric`, `vielbein_diagonal`, and `python-field-theory.json`, check `sqrt_det_g_equals_cos_z`).
- The 25 independent nonzero Christoffel symbols (Section 6.3; Notebook 06a, In [9]; formula `christoffel_nonzero` of both records, check `christoffel_count`).
- The vielbein postulate has exactly one solution, the canonical spin connection, and its lowered form is antisymmetric; for the author's metric it has exactly 12 independent nonzero components, each a rate (a_4', $a_4' - b_4'/(2b_4)$ or H) times a nonvanishing factor (Sections 6.4 and 6.6; Notebook 06a, In [11]; formula `omega_nonzero` of both records; checks `vielbein_postulate`, `spin_connection_antisymmetric`, `omega_components`, and at $b_4 = 1$ `Omega_vanishes_iff_a4prime_and_H_vanish`).
- $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$ is the unique traceless solution of the defining property; it makes the curved gammas covariantly constant; $\Omega_{x0} = \Omega_{x4} = 0$ (Section 6.7; Notebook 06a, In [13]; checks `S_rotates_gamma_with_omega`, `covariant_constancy_D_mu_gamma_nu`, `Omega_x0_and_Omega_x4_vanish`).
- $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ in the diagonal vielbein, for every $H > 0$, a_4 and b_4, and $3H\gamma^{(x0)}$ for a constant b_4: the time-direction terms $\pm\frac{1}{2}a_4'$ of the three inflating

and the three deflating directions cancel, the extra times leave $\frac{3}{4}b_4'/b_4$, the six hidden terms $\frac{1}{2}H$ add; equivalently, the divergence form (Sections 6.8 and 6.9; Notebook 06a, In [15] and In [18]; formulas `gammaOmega_per_direction`, `gammaOmega_total`; checks `gammaOmega_per_direction`, `gammaOmega_total`, `gammaOmega_divergence_form` with b_4, and at $b_4 = 1$ `gammaOmega_x4_terms_cancel`, `gamma_mu_Omega_mu_equals_3H_gamma_x0`, `gamma_Omega_equals_3H_gamma0`).

- The Dirac operator written out, all sixteen components; the term $M\Psi$ with $MM = (9H^2 - \frac{9}{16}(b_4'/b_4)^2)\,1$ vanishes only for $\Psi = 0$ unless $|b_4'/b_4| = 4H$, and for a constant b_4 never, for both fields (Section 6.10; Notebook 06a, In [20]; checks `Dirac_operator_explicit_G`, `Dirac_operator_explicit_C`, `gravity_term_square_b4`, and at $b_4 = 1$ `nontriviality_1_dirac16complex`, `nontriviality_2_dirac16complex00`).

- The negative control (at $b_4 = 1$): with inflating extra times the contraction is $3a_4'\gamma^{(x4)} + 3H\gamma^{(x0)}$; the cancellation of the a_4' terms is caused by the deflation (Section 6.10; Notebook 06a, In [22]; lead report, check `negative_control_inflating_extra_times`).

- Local spin covariance $\Omega_\mu' = R\Omega_\mu R^{-1} - (\partial_\mu R)R^{-1}$, $\gamma'^\mu = R\gamma^\mu R^{-1}$, $F' = RFR^{-1}$ (Sections 6.15 and 6.17; Notebook 06b, In [12] and In [15]).

- In the frame boosted with $b = \beta x_4 + b_0$, $\gamma'^\mu\Omega_\mu' = \frac{6H-\beta}{2}(\cosh b\,\gamma^{(x0)} - \sinh b\,\gamma^{(x4)}) + \frac{3}{4}\frac{b_4'}{b_4}(\cosh b\,\gamma^{(x4)} - \sinh b\,\gamma^{(x0)})$, zero for $\beta = 6H$ and a constant b_4, while $\Omega_\mu' \neq 0$ for $x1, \ldots, x7$ (Section 6.16; Notebook 06b, In [8] and In [10]; at $b_4 = 1$ both scope reports, checks `boosted_frame_gammaOmega_formula`, `boosted_frame_gammaOmega_vanishes`).

- The Ricci tensor (all components by hand in Section 3.25): with b_4 ten nonzero mixed components, two of them off the diagonal and proportional to b_4', and $R = 6a_4'^2 - 3a_4'b_4'/b_4 + 3b_4''/b_4 - 42H^2$; at $b_4 = 1$, $R = 6(a_4'^2 - 7H^2)$. By hand in Section 6.17, $R^{x0}{}_{x0} = -6H^2$ for every b_4 and $R^{x4}{}_{x4} = 3(a_4'^2 + a_4'') + 3(\alpha_t^2 + \alpha_t')$, which is $6a_4'^2$ at $b_4 = 1$: the metric is never flat, and the contraction is blind to the deflation while the metric is not; $F_{\mu\nu} = \frac{1}{2}R_{ab\mu\nu}S^{ab}$ in all 28 planes; $F'_{x0x1} \neq 0$ in the boosted frame (Section 6.17, whose table names the records that prove the same; Notebook 06b, In [13] and In [15]).

- The rescaling $\Psi = \sin^{-1/2}(z)\,b_4^{-3/4}\,\chi$ removes the term; with $U = \frac{\lambda}{2}S^2$ it becomes $\lambda S[\chi]/(b_4^{3/2}\sin z)$ (Section 6.18; Notebook 06b, In [17]; at $b_4 = 1$ checks `rescaling_removes_the_connection_term`, `rescaled_equation_quadratic_potential`).

- The mixed contraction equals $\Omega^{ss} - \Omega^{tt}$: it keeps 6, reverses 6 and deletes 16 of the 28 parts; it agrees with the correct one in the polar plane and deletes the whole connection in the Milne wedge (Section 6.23; Notebook 06c, In [4], In [6], In [8]).

- Only $c = 3H$ makes the hidden-direction operator antisymmetric for the weight $\cos z$ (times the constant $b_4^{3/2}$ along $x0$), up to the boundary term $[\sin z\, p\, q]$ (Section 6.24; Notebook 06c, In [15]; formula `hidden_direction_hermiticity`; check `good_sector_hermiticity_curved`).

- In the diagonal vielbein the canonical connection drops out of the symmetric Lagrangian, and $\gamma^\mu\Omega_\mu$ is the half-density term of its field equation (Section 6.29; check `connection_free_lagrangian_same_equations`, at $b_4 = 1$).

COMPUTED (by the notebooks):

- The central differences of Notebook 06a, In [19], reproduce the constant $3H$ to 1.9×10^{-9}, the size $18h^2$ expected for the step $h = 10^{-5}$, and $\frac{3}{4}b_4'/b_4$ for the illustrative $b_4 = 1 + \frac{1}{2}\sin x_4$ to 2.5×10^{-11}.
- The figures at the sample points: in Notebook 06a $H = 1$, $z = \pi/4$, $a_4 = a_4' = \frac{1}{2}$, $b_4 = 1$, $b_4' = \frac{1}{2}$, for example $\omega_{x1\,x1x4} = 0.78$, $\omega_{x5\,x5x0} = -0.57$, $\omega_{x5\,x4x5} = -0.14$; in Notebook 06b the same with $b_4' = 0$, the largest spinor curvature $\|F_{\mu\nu}\| = 3.633$ (in units of H^2; In [16]) with 27 of 28 planes curved there.
- Exact counts made by the notebooks themselves, not stated in the Revision record: 13 nonzero components of the boosted spin connection (Notebook 06b, In [7]); 78 nonzero Riemann components with $\mu < \nu$ (Notebook 06b, In [13]); for the mixed contraction, $\frac{3H}{2}\gamma^{(x0)} + \frac{3}{2}(a_4' - \frac{b_4'}{2b_4})\gamma^{(x4)}$, 15 violated pairs with 288 nonzero entries, and 15 pairs in which its defining property fails (Notebook 06c, In [10] and In [13]). These describe a contraction that the record does not use.

ASSUMED: the author's metric with b_4 and the roles of his coordinates (the input of the theory); the illustrative histories $a_4 = x_4$, $b_4 = 1$ with $H = 1$ in figures 2 and 9 of Notebook 06a (the prescribed background of Chapter 3) and $b_4 = 1 + \frac{1}{2}\sin x_4$ in figure 8 (no result depends on them); two standard theorems quoted without proof: Jacobi's formula for the derivative of a determinant (Section 6.15) and the general identity $F_{\mu\nu} = \frac{1}{2}R_{ab\mu\nu}S^{ab}$, which is however checked exactly for the author's metric (Section 6.17); and the record's statement about the author's notebook contraction (Section 6.23), which this book takes from `Revision/SPEC.md`.

HYPOTHESIS and OPEN: this chapter states no hypothesis. The boundary condition at the patch end $z = \pi/2$, needed for the antisymmetry of the hidden-direction operator, is not fixed here (Section 6.24); Chapter 14 assumes the Z_2 mirror. Nothing in this chapter concerns the creation of universes or matter and antimatter.

6.31 Exercises

Exercise 1 (the sphere). The unit sphere has the metric $ds^2 = d\theta^2 + \sin^2\theta\, d\varphi^2$ $(0 < \theta < \pi)$, the frame metric $\eta = \mathrm{diag}(1, 1)$, the vielbein factors $f_\theta = 1$, $f_\varphi = \sin\theta$, and the gammas $\gamma^0 = \sigma_1$, $\gamma^1 = \sigma_2$. Compute the Christoffel symbols, the spin connection, Ω_μ, $\sum_\mu \gamma^\mu\Omega_\mu$ (check it with the divergence form) and $F_{\theta\varphi}$. Is the sphere flat?

Answer. Case (c) of Section 6.3: $\Gamma^\theta{}_{\varphi\varphi} = -f_\varphi\partial_\theta f_\varphi/f_\theta^2 = -\sin\theta\cos\theta$; case (b): $\Gamma^\varphi{}_{\varphi\theta} = \partial_\theta \ln\sin\theta = \cot\theta$; all others vanish. By Section 6.6 the only nonzero component is $\omega_{\varphi\,10} = \eta_{11}\,\partial_\theta f_\varphi/f_\theta = \cos\theta$, so $\omega_{\varphi\,01} = -\cos\theta$. With $S^{01} = \frac{1}{2}\sigma_1\sigma_2 = \frac{i}{2}\sigma_3$: $\Omega_\varphi = -\cos\theta\, S^{01} = -\frac{i}{2}\cos\theta\,\sigma_3$ and $\Omega_\theta = 0$. With $\gamma^\varphi = \sigma_2/\sin\theta$: $\sum_\mu \gamma^\mu\Omega_\mu = \frac{\sigma_2}{\sin\theta}\big(-\frac{i}{2}\cos\theta\,\sigma_3\big) = -\frac{i\cot\theta}{2}\sigma_2\sigma_3 = -\frac{i\cot\theta}{2}\,i\sigma_1 = \frac{\cot\theta}{2}\sigma_1$. Divergence form with $\sqrt{|g|} = \sin\theta$: $\frac{1}{2\sin\theta}(\partial_\theta(\sin\theta\,\sigma_1) + \partial_\varphi(\sin\theta\cdot\sigma_2/\sin\theta)) = \frac{\cos\theta}{2\sin\theta}\sigma_1$, the same. Finally $F_{\theta\varphi} = \partial_\theta\Omega_\varphi - \partial_\varphi\Omega_\theta + [\Omega_\theta, \Omega_\varphi] = \partial_\theta\big(-\frac{i}{2}\cos\theta\,\sigma_3\big) = \frac{i}{2}\sin\theta\,\sigma_3 \neq 0$. The sphere is curved: unlike the polar plane of Section 6.5, here no change of frame can remove the spin connection (Section 6.17). (Check with the theorem of Section 6.17: $R^\theta{}_{\varphi\theta\varphi} = \sin^2\theta$ for the unit sphere, so $R_{01\theta\varphi} = \eta_{00}f_\theta R^\theta{}_{\varphi\theta\varphi}/f_\varphi = \sin\theta$ and $\frac{1}{2}(R_{01\theta\varphi}S^{01} + R_{10\theta\varphi}S^{10}) = \sin\theta\, S^{01} = \frac{i}{2}\sin\theta\,\sigma_3$.)

Exercise 2 (an extra time by hand). Compute $\omega_{x6\,ab}$ for the author's metric with the formula of Section 6.6 and then $\gamma^{x6}\Omega_{x6}$, without looking at Section 6.8. Why is the coefficient of $\gamma^{(x4)}$ negative?

Answer. Take b_4 constant, so that $f_6 = e^{-a_4} b_4^{1/2} s$ has $\partial_4 f_6 = -a_4' f_6$ (for a changing b_4 replace $-a_4'$ by α_t throughout); and $\partial_0 f_6 = H \cot z \, f_6$. With $\omega_{\mu\,\mu b} = \eta_{\mu\mu} \partial_b f_\mu / f_b$ and $\eta_{66} = -1$: $\omega_{x6\,x6\,x4} = (-1)(-a_4' f_6)/1 = a_4' f_6$, hence $\omega_{x6\,x4\,x6} = -a_4' f_6$; and $\omega_{x6\,x6\,x0} = (-1) H \cot z \, f_6 / \cot z = -H f_6$. So $\Omega_{x6} = -f_6 (a_4' S^{x4x6} + H S^{x6x0})$ and $\gamma^{x6} \Omega_{x6} = \frac{\gamma^{(x6)}}{f_6}(-f_6)(\frac{a_4'}{2}\gamma^{(x4)}\gamma^{(x6)} + \frac{H}{2}\gamma^{(x6)}\gamma^{(x0)}) = -\frac{a_4'}{2}\gamma^{(x6)}\gamma^{(x4)}\gamma^{(x6)} - \frac{H}{2}\gamma^{(x6)}\gamma^{(x6)}\gamma^{(x0)}$. Since $\gamma^{(x6)}\gamma^{(x4)}\gamma^{(x6)} = -\gamma^{(x4)}(\gamma^{(x6)})^2 = \gamma^{(x4)}$ and $(\gamma^{(x6)})^2 = -1$, $\gamma^{x6}\Omega_{x6} = -\frac{a_4'}{2}\gamma^{(x4)} + \frac{H}{2}\gamma^{(x0)}$. The coefficient of $\gamma^{(x4)}$ is negative because the extra time shrinks ($\partial_4 f_6 = -a_4' f_6$) while a 3-space direction grows; this is the sign that cancels the 3-space terms.

Exercise 3 (a general deflation rate). Take $b_4 = 1$ and replace the extra-time factors by $e^{-k a_4} s$ with a constant k (the author's metric has $k = 1$, the negative control $k = -1$). Use the divergence form to find the coefficient of $\gamma^{(x4)}$ in $\sum_\mu \gamma^\mu \Omega_\mu$. For which k does it vanish?

Answer. With $f_4 = 1$ the product of the other seven factors is the whole volume factor: $\sqrt{|g|} = e^{3a_4} s^3 \cdot e^{-3k a_4} s^3 \cdot \cot z = e^{3(1-k)a_4} \cos z$ ($s^6 \cot z = \sin z \cot z = \cos z$). The time contribution of the divergence form is $\frac{1}{2\sqrt{|g|}} \partial_4 \sqrt{|g|}\, \gamma^{(x4)} = \frac{3(1-k)a_4' e^{3(1-k)a_4} \cos z}{2 e^{3(1-k)a_4} \cos z} \gamma^{(x4)} = \frac{3}{2}(1-k) a_4' \gamma^{(x4)}$ (the chain rule). For $k = 1$ (the author's deflation) it is 0; for $k = -1$ it is $3a_4'$, the negative control of Section 6.10. It vanishes only for $k = 1$, exactly when the 7-volume does not change with time. (The hidden term is $3H$ for every k, because $\prod_{c \neq x0} f_c = e^{3(1-k)a_4} \sin z$ and the factor $e^{3(1-k)a_4}$ cancels in the division.)

Exercise 4 (the boosted contraction in numbers). Take $H = 1$, $b_0 = 0$ and the rate $\beta = 3$. Give the coefficients of $\gamma^{(x0)}$ and $\gamma^{(x4)}$ in $\gamma'^\mu \Omega'_\mu$ at $x_4 = 0$ and at $x_4 = \frac{1}{3}$. Which rate β gives $-3\gamma^{(x0)}$ at $x_4 = 0$?

Answer. By Section 6.16, for a constant b_4, the coefficients are $\frac{6-\beta}{2}\cosh b$ and $-\frac{6-\beta}{2}\sinh b$ with $b = \beta x_4$. Here $\frac{6-3}{2} = 1.5$. At $x_4 = 0$: $b = 0$, coefficients 1.5 and 0. At $x_4 = \frac{1}{3}$: $b = 1$, $\cosh 1 = 1.5431$, $\sinh 1 = 1.1752$, so the coefficients are $1.5 \cdot 1.5431 = 2.3146$ and $-1.5 \cdot 1.1752 = -1.7628$. At $x_4 = 0$ the coefficient of $\gamma^{(x0)}$ is $\frac{6-\beta}{2}$, which equals -3 for $\beta = 12$. A frame can thus give the contraction any multiple of $\gamma^{(x0)}$ at one instant; the value is not a property of the metric.

Exercise 5 (rescaling with a general power). Take b_4 constant and let $\Psi = \sin^\alpha(z)\, \chi$ with a constant α in the diagonal vielbein. Show that $\sum_\mu \gamma^\mu D_\mu \Psi = \sin^\alpha z \, (\sum_\mu \gamma^\mu \partial_\mu \chi + 3H(2\alpha+1)\gamma^{(x0)}\chi)$. Which α removes the term, and which leaves it unchanged?

Answer. By the product rule, and because only x_0 appears in $\sin^\alpha z$,

$$\sum_\mu \gamma^\mu D_\mu (\sin^\alpha z\, \chi) = \sin^\alpha z \sum_\mu \gamma^\mu \partial_\mu \chi + (\gamma^{x0} \partial_0 \sin^\alpha z + 3H \sin^\alpha z\, \gamma^{(x0)})\chi.$$

With $\gamma^{x0} = \tan z\, \gamma^{(x0)}$ and $\partial_0 \sin^\alpha z = 6H\alpha \sin^{\alpha-1} z \cos z$ (the power rule and the chain rule),

$$\tan z\, \partial_0 \sin^\alpha z = \frac{\sin z}{\cos z}\, 6H\alpha \sin^{\alpha-1} z \cos z = 6H\alpha \sin^\alpha z.$$

The bracket is $(6H\alpha + 3H)\sin^\alpha z\, \gamma^{(x0)} = 3H(2\alpha+1)\sin^\alpha z\, \gamma^{(x0)}$, which gives the formula. $\alpha = -\frac{1}{2}$ removes the term (Section 6.18), and $\alpha = 0$ leaves it unchanged. This is the factor $3H(2\alpha+1)$ that the record's exact solution family contains (`field-theory.json`, formula `exact_solutions`).

Exercise 6 (mixed components). Using $\omega_\mu{}^b{}_a = -\eta_{aa}\eta_{bb}\,\omega_\mu{}^a{}_b$ (Section 6.4), show that the mixed components of a time-time pair are antisymmetric and those of a boost pair symmetric. Then

compute Ω^{nb}_{x2} and Ω^{nb}_{x7} for the author's metric.

Answer. For a time-time pair $\eta_{aa}\eta_{bb} = (-1)(-1) = +1$, so $\omega_\mu{}^b{}_a = -\omega_\mu{}^a{}_b$: antisymmetric. For a boost pair $\eta_{aa}\eta_{bb} = -1$, so $\omega_\mu{}^b{}_a = +\omega_\mu{}^a{}_b$: symmetric, and in $\frac{1}{2}\sum_{a,b}\omega_\mu{}^a{}_b S^{ab}$ its two terms cancel because $S^{ba} = -S^{ab}$. For $x2$ the pair $(x2, x4)$ is a boost pair (deleted) and $(x2, x0)$ a space-space pair (kept): $\Omega^{nb}_{x2} = e^{a_4} s\, H\, S^{x2x0}$. For $x7$ the pair $(x4, x7)$ is time-time (sign reversed) and $(x0, x7)$ a boost pair (deleted): $\Omega^{nb}_{x7} = -\omega_{x7\,x4x7} S^{x4x7} = +e^{-a_4} b_4^{1/2} s\,(a_4' - \frac{b_4'}{2b_4}) S^{x4x7}$.

Exercise 7 (the hidden operator in numbers). Take $p = q = 1$ (constant functions) and integrate the identity of Section 6.24 over the whole patch $0 \le x_0 \le \pi/(12H)$. Compare the left side with the boundary term for $c = 3H$ and for $c = \frac{3}{2}H$.

Answer. With $p = q = 1$, $A_c 1 = c$, so the left side is $\int \cos z \cdot 2c\, dx_0 = 2c \int_0^{\pi/(12H)} \cos(6Hx_0)\, dx_0 = 2c \cdot \frac{1}{6H} = \frac{c}{3H}$ (the 7-volume integral of Chapter 3; the constant factor $b_4^{3/2}$ is left out on both sides). The boundary term is $[\sin z\, p\, q]_{z=0}^{z=\pi/2} = 1 - 0 = 1$. For $c = 3H$ the left side is 1, equal to the boundary term: nothing else is left. For $c = \frac{3}{2}H$ it is $\frac{1}{2}$, and the difference $\frac{1}{2} - 1 = -\frac{1}{2}$ is the integral of the leftover $-3H\cos z$, $-3H \cdot \frac{1}{6H} = -\frac{1}{2}$, which no boundary term can absorb.

Exercise 8 (which pairs break). Without a computer, explain why $D^{nb}_{x1}\gamma^{x2} = 0$ although $\Omega^{nb}_{x1} \neq \Omega_{x1}$, and why the row $x0$ of figure 5 of Notebook 06c is white.

Answer. By Section 6.23, $D^{nb}_{x1}\gamma^{x2} = [\Omega^{nb}_{x1} - \Omega_{x1}, \gamma^{x2}] = -f_1 a_4' [S^{x1x4}, \gamma^{(x2)}]/f_2$. By the vector rule $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b$, which vanishes when c is neither a nor b; here $c = x2$ is neither $x1$ nor $x4$, so the commutator is zero. The row $x0$ is white because $\Omega_{x0} = 0$ (Section 6.6) and also $\Omega^{nb}_{x0} = 0$ (it is built from the same components, all zero for $\mu = x0$), so their difference vanishes and $D^{nb}_{x0}\gamma^\nu = D_{x0}\gamma^\nu = 0$ for every ν.

7 The two fields and their Lagrangians; Grassmann numbers; Euler-Lagrange equations

This chapter writes down the laws that the two fields of the book obey in the author's primordial gravitational field. A law of this kind is not guessed equation by equation. One writes down a single function, the **Lagrangian**, and a single principle, the **principle of stationary action**, and the field equations follow from them by a fixed recipe, the **Euler-Lagrange equations**. The chapter teaches the recipe from zero, then the strange numbers (Grassmann numbers) of which the field dirac16complex is made, then the Lagrangian of the two fields, its field equations written out in the author's metric, and finally what happens to real fields and why charge conjugation is a matrix.

7.1 What this chapter does

The two fields. The book studies two fields that live on the author's eight-dimensional space-time. Both attach to every point of space-time a column of 16 complex numbers $\Psi = (\Psi_1, \ldots, \Psi_{16})$, and both change under the turnings of the eight directions in the same way, as a **spinor** of the group Pin(4,4) (Chapter 5). They differ in one respect only, the kind of numbers their 16 components are:

- **dirac16complex** has components that **anticommute**: for two of its components $\Psi_A \Psi_B = -\Psi_B \Psi_A$. Ordinary numbers cannot do this; the numbers that can are called **Grassmann**

numbers, and Sections 7.10 to 7.13 build them from nothing. The Revision record defines the components of dirac16complex as Grassmann numbers (Revision/SPEC.md, section 3); this field is later turned into a quantum field (Chapter 10).

- **dirac16complex00** has ordinary commuting complex components. It is a classical field, the 16-component analogue in eight dimensions of the four-component wave function that Dirac wrote down in 1928; it is not quantised.

The coordinates. As everywhere in this book, the eight coordinates carry the author's names $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates; x_4 is the time; x_5, x_6, x_7 are three **extra times**, time-like directions which **deflate exponentially** as 3-space inflates; x_0 is the hidden space direction. With $z = 6Hx_0$, $0 < z < \pi/2$, the author's constant $H > 0$ and a function $a_4(x_4)$ of the time, the author's metric is (Chapter 3)

$$ds^2 = e^{2a_4} \sin^{1/3} z \, (dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2 - e^{-2a_4} \sin^{1/3} z \, (dx_5^2 + dx_6^2 + dx_7^2) + \cot^2 z \, dx_0^2.$$

3-space has the scale factor $e^{a_4} \sin^{1/6} z$, the three extra times the scale factor $e^{-a_4} \sin^{1/6} z$: when a_4 grows, 3-space inflates and the extra times deflate. The signature is (4,4): x_0, x_1, x_2, x_3 are space-like (positive entries), x_4, x_5, x_6, x_7 time-like (negative entries).

What the chapter derives, in order.

- Sections 7.2 to 7.5: the action, the principle of stationary action, and the Euler-Lagrange equation, from one-variable calculus only; what changes for fields; and the first sign that the extra times are unusual: a wave along an extra time grows instead of oscillating. Notebook 07d computes every step (30 checks, 8 figures).
- Sections 7.10 to 7.13: Grassmann numbers from zero, the rules for their products, conjugation and derivatives, which bilinear forms survive for real columns, the powers of the scalar density $S = \bar{\Psi}\Psi$ (defined in Section 7.12; $S^{17} = 0$), and field equations with Grassmann numbers. Notebook 07a builds a Grassmann algebra in a few lines of Python (38 checks, 7 figures).
- Sections 7.18 to 7.23: the geometry the fields live in, the common Lagrangian of the two fields, its reality, the total divergence, why the spin connection drops out of the Lagrangian but not out of the field equation, the Euler-Lagrange equations of both fields, their explicit, block and evolution forms in the author's metric, non-triviality [1] and [2] with their exact scope, the six exact senses in which the field equations are self-consistent, and an exact family of solutions. Notebook 07b derives all of it exactly and compares it with the Revision record (47 checks, 6 figures).
- Sections 7.28 and 7.29: real fields; the author's Majorana-type Lagrangian, which is empty for real Grassmann fields (the negative control of the Revision record); and why **charge conjugation is a matrix**: for a real field, plain complex conjugation changes nothing. Notebook 07c computes the charge-conjugation matrices $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$ and the mass reversal by the real matrix Γ (23 checks, 4 figures).
- Section 7.34 lists what was proved, computed and assumed; Section 7.35 has exercises with complete answers.

The notebooks. The four notebooks appear in the order d, a, b, c, because Notebook 07d derives the recipe that the other three use. Each is complete in itself and may be run in any order. Before each notebook the book prints the complete instructions to run it, then the complete text of the notebook with its outputs and figures, then a section that explains every line of its code.

Statuses. Every statement carries one of five labels. PROVED: exact, derived here line by line and, where the Revision record contains it, verified there by a named check of a named report. COMPUTED: a number produced by a program, with its uncertainty. ASSUMED: used, not derived. HYPOTHESIS: a proposal that is being investigated and is not claimed. OPEN: a question that is not answered. The Revision reports cited in this chapter are `Revision/theory/reports/python-field-theory.json` (the sympy verifier, 70 of 70 checks pass), `Revision/theory/reports/wolfram-field-theory.json` (the Wolfram verifier, 84 of 84 checks pass), `Revision/theory/reports/python-scope.json` (14 of 14) and `Revision/theory/reports/wolfram-scope.json` (15 of 15) for the scope of the statements, the formula record `Revision/theory/field-theory.json`, and `Revision/lead_checks/reports/charge-conjugation-and-u1.json` (12 of 12) for charge conjugation. These counts are those that the reports state at the time of writing; each notebook reads the checks it relies on from the reports themselves and stops if one is missing or does not pass.

7.2 Paths, the action and the first variation

We begin with the simplest possible system, a particle that moves along a line, and learn the principle there. Everything carries over to fields in Section 7.5.

A path. A **path** (or motion) is a function $q(t)$ that gives the position q of the particle at every time t between a start time 0 and an end time T. Its **velocity** is $\dot{q} = dq/dt$ and its **acceleration** $\ddot{q} = d^2q/dt^2$ (a dot over a letter is the derivative with respect to the time t).

The Lagrangian. A **Lagrangian** is a function $L(q, \dot{q})$ of the position and the velocity. For the **oscillator**, a particle of mass 1 on a spring, it is the kinetic energy minus the potential energy:

$$L(q, \dot{q}) = \tfrac{1}{2}\dot{q}^2 - \tfrac{1}{2}\omega^2 q^2,$$

where $\omega > 0$ is a fixed number, the **angular frequency** of the spring. Here L is a function of two ordinary variables; we call them q and $\dot{q}$ because along a path we shall put the position and the velocity of the path into them. The two **partial derivatives** of L (Chapter 2) are $\partial L/\partial q = -\omega^2 q$ (the velocity held fixed) and $\partial L/\partial \dot{q} = \dot{q}$ (the position held fixed).

The action. The **action** of a path is one number for the whole path:

$$S[q] = \int_0^T L\big(q(t), \dot{q}(t)\big)\, dt.$$

At every time we put the position and the velocity of the path into L and add up (integrate) the values over the time interval. The square brackets in $S[q]$ say that S depends on the whole function q, not on one number; a rule that takes a function and gives a number is called a **functional**.

The principle of stationary action (ASSUMED: it is the starting principle of classical mechanics and of classical field theory, not derived from anything simpler). Among all paths with the same end values $q(0) = q_A$ and $q(T) = q_B$, the particle follows one whose action does not change to first

order when the path is changed a little. To make "changed a little" precise, take a fixed **shape** $\xi(t)$ with $\xi(0) = \xi(T) = 0$ (so that the changed path keeps the end values) and a small number ϵ, and form the **varied path** $q + \epsilon\xi$. Its action $S[q + \epsilon\xi]$ is an ordinary function of the one number ϵ. The **first variation** is its slope at $\epsilon = 0$:

$$S_1 = \frac{d}{d\epsilon} S[q + \epsilon\xi]\Big|_{\epsilon=0}.$$

A path is **stationary** if $S_1 = 0$ for every shape ξ; the principle says that the true motion is stationary.

For the oscillator the action is a polynomial in ϵ. Put the varied path into the Lagrangian:

$$L(q + \epsilon\xi, \dot{q} + \epsilon\dot{\xi}) = \tfrac{1}{2}(\dot{q} + \epsilon\dot{\xi})^2 - \tfrac{1}{2}\omega^2(q + \epsilon\xi)^2$$

(the velocity of the varied path is $\dot{q} + \epsilon\dot{\xi}$, because the derivative of a sum is the sum of the derivatives and the constant ϵ comes out of the derivative);

$$= \tfrac{1}{2}\dot{q}^2 + \epsilon\,\dot{q}\dot{\xi} + \tfrac{1}{2}\epsilon^2\dot{\xi}^2 - \tfrac{1}{2}\omega^2 q^2 - \epsilon\,\omega^2 q\xi - \tfrac{1}{2}\epsilon^2\omega^2\xi^2$$

(the square of a sum, $(a+b)^2 = a^2 + 2ab + b^2$, applied twice);

$$= \Big[\tfrac{1}{2}\dot{q}^2 - \tfrac{1}{2}\omega^2 q^2\Big] + \epsilon\Big[\dot{q}\dot{\xi} - \omega^2 q\xi\Big] + \epsilon^2\Big[\tfrac{1}{2}\dot{\xi}^2 - \tfrac{1}{2}\omega^2\xi^2\Big]$$

(the terms collected by the power of ϵ). Integrating from 0 to T term by term:

$$S[q + \epsilon\xi] = S_0 + S_1\,\epsilon + S_2\,\epsilon^2, \qquad S_1 = \int_0^T (\dot{q}\dot{\xi} - \omega^2 q\xi)\,dt, \qquad S_2 = \int_0^T (\tfrac{1}{2}\dot{\xi}^2 - \tfrac{1}{2}\omega^2\xi^2)\,dt,$$

with $S_0 = S[q]$. The coefficient S_1 of ϵ is exactly the first variation (the slope of a polynomial at 0 is its coefficient of the first power), and the coefficient S_2 contains only the shape ξ, not the path: it is the same for every path (PROVED; Notebook 07d checks both facts exactly, In [3]).

The example of Notebook 07d. Take $\omega = 1$, $T = 1$, $q(0) = 0$, $q(1) = 1$. The **true path** is $q(t) = \sin t / \sin 1$: it has $\ddot{q} = -\sin t/\sin 1 = -q$ (the second derivative of $\sin t$ is $-\sin t$), which is Newton's law $\ddot{q} = -\omega^2 q$ for the spring, and $q(0) = 0$, $q(1) = \sin 1/\sin 1 = 1$. Two wrong paths with the same end values are the **line** $q = t$ and the **parabola** $q = t^2$. The shapes are $\xi_n(t) = \sin(n\pi t)$ for $n = 1, 2, 3$; each vanishes at $t = 0$ and at $t = 1$, because $\sin 0 = \sin(n\pi) = 0$.

One first variation by hand. For the line, $\dot{q} = 1$, and for $\xi_1 = \sin\pi t$, $\dot{\xi}_1 = \pi\cos\pi t$:

$$S_1 = \int_0^1 (\pi\cos\pi t - t\sin\pi t)\,dt$$

(the formula for S_1 with $\omega = 1$);

$$= \big[\sin\pi t\big]_0^1 - \int_0^1 t\sin\pi t\,dt = 0 - \int_0^1 t\sin\pi t\,dt$$

(an antiderivative of $\pi\cos\pi t$ is $\sin\pi t$, which is 0 at both ends). The last integral is done by **integration by parts** (Section 7.3 derives it; here it is used with $f = t$ and $g = -\cos(\pi t)/\pi$): $\int_0^1 t\sin\pi t\,dt = \big[-t\cos(\pi t)/\pi\big]_0^1 + \int_0^1 \cos(\pi t)/\pi\,dt = 1/\pi + 0 = 1/\pi$, since $\cos\pi = -1$ and $\sin\pi = \sin 0 = 0$. So

$$S_1 = -\frac{1}{\pi} = -0.318310,$$

the value that Notebook 07d prints for the line and $n = 1$ (In [2]). The line is not stationary: its action changes to first order. For the true path the notebook finds $S_1 = 0$ exactly for all three shapes, and for the two wrong paths $S_1 \neq 0$ for all three (In [2] and In [3]; PROVED by exact integration with sympy).

A minimum, or only stationary? The coefficient S_2 decides what kind of stationary point the true path is. Take the shape $\xi_1 = \sin(\pi t/T)$ on an interval of length T. Then $\dot\xi_1 = (\pi/T)\cos(\pi t/T)$ (the chain rule), and

$$S_2 = \int_0^T \Big(\frac{\pi^2}{2T^2}\cos^2\frac{\pi t}{T} - \frac{\omega^2}{2}\sin^2\frac{\pi t}{T}\Big)dt$$

(the definition of S_2 with this shape);

$$= \frac{\pi^2}{2T^2}\cdot\frac{T}{2} - \frac{\omega^2}{2}\cdot\frac{T}{2}$$

(each of the two integrals is $T/2$: the double-angle formula $\cos 2x = 2\cos^2 x - 1$ gives $\cos^2(\pi t/T) = \frac{1}{2}(1 + \cos(2\pi t/T))$; the interval from 0 to T is one full period of $\cos(2\pi t/T)$, and indeed $\int_0^T \cos(2\pi t/T)\,dt = \big[\frac{T}{2\pi}\sin(2\pi t/T)\big]_0^T = 0$ because $\sin 2\pi = \sin 0 = 0$; so $\int_0^T \cos^2(\pi t/T)\,dt = \frac{1}{2}T = T/2$, and because $\sin^2 = 1 - \cos^2$, $\int_0^T \sin^2(\pi t/T)\,dt = T - T/2 = T/2$);

$$= \frac{T}{4}\Big(\frac{\pi^2}{T^2} - \omega^2\Big)$$

(the common factor $T/4$ taken out). For $T < \pi/\omega$ the bracket is positive, so $S_2 > 0$ and the action of $q + \epsilon\xi_1$ is $S_0 + S_2\epsilon^2$ with a positive S_2: the true path is a **minimum** along this shape. For $T > \pi/\omega$ the coefficient is negative: the true path is still stationary ($S_1 = 0$), but along ξ_1 the action is a maximum, while along faster shapes (ξ_n with large n) it is still a minimum; such a point is called a **saddle**. This is why the principle is called the principle of STATIONARY action and not of least action (PROVED; Notebook 07d checks the formula with T as a symbol and its sign at $T = 1$ and $T = 4$, In [4], and draws Figure 07d.1). With $T = 1$, $\omega = 1$ the formula gives $S_2 = (\pi^2 - 1)/4 = 2.217401$ for ξ_1; the notebook prints this value and $S_2 = \pi^2 - 1/4 = 9.619604$ for ξ_2 and $9\pi^2/4 - 1/4 = 21.956610$ for ξ_3 (In [3]).

7.3 From the principle to the Euler-Lagrange equation

Computing the action of every path is not how one finds the true path. Instead the principle is turned into an equation that the true path must satisfy at every time. This takes three lines and one lemma.

Integration by parts. The **product rule** of differentiation says $\frac{d}{dt}(fg) = \dot{f}g + f\dot{g}$ for two functions $f(t)$, $g(t)$. Integrate both sides from 0 to T. The left side is the integral of a derivative, so by the fundamental theorem of calculus it is the difference of the end values, which we write $[fg]_0^T = f(T)g(T) - f(0)g(0)$:

$$[fg]_0^T = \int_0^T \dot{f}g\,dt + \int_0^T f\dot{g}\,dt \qquad \Longrightarrow \qquad \int_0^T f\dot{g}\,dt = [fg]_0^T - \int_0^T \dot{f}g\,dt.$$

The second form moves the derivative from g to f at the price of a minus sign and the **boundary term** $[fg]_0^T$.

Line 1. Differentiate the action of the varied path with respect to ϵ:

$$\frac{d}{d\epsilon} S[q+\epsilon\xi]\Big|_{\epsilon=0} = \int_0^T \Big(\frac{\partial L}{\partial q}\,\xi + \frac{\partial L}{\partial \dot{q}}\,\dot{\xi}\Big)dt.$$

Rule: the derivative may be taken inside the integral (true for the smooth functions of this book on a finite interval; a standard theorem of calculus, ASSUMED here), and inside, L depends on ϵ through its first argument $q+\epsilon\xi$, whose derivative with respect to ϵ is ξ, and through its second argument $\dot{q}+\epsilon\dot{\xi}$, whose derivative is $\dot{\xi}$; the chain rule for a function of two variables (Chapter 2) adds the two contributions.

Line 2. Integrate the second term by parts with $f = \partial L/\partial\dot{q}$ and $g = \xi$:

$$= \int_0^T \frac{\partial L}{\partial q}\,\xi\,dt + \Big[\frac{\partial L}{\partial \dot{q}}\,\xi\Big]_0^T - \int_0^T \frac{d}{dt}\Big(\frac{\partial L}{\partial \dot{q}}\Big)\xi\,dt.$$

Line 3. The boundary term vanishes, because $\xi(0) = \xi(T) = 0$; collect the two integrals:

$$= \int_0^T E(t)\,\xi(t)\,dt, \qquad E = \frac{\partial L}{\partial q} - \frac{d}{dt}\frac{\partial L}{\partial \dot{q}}.$$

The function $E(t)$ is the **Euler-Lagrange expression** of the path. In $\partial L/\partial q$ and $\partial L/\partial\dot{q}$ the path's own position and velocity are put in after differentiating, and then $\frac{d}{dt}$ is an ordinary time derivative along the path.

The fundamental lemma. If a continuous function $E(t)$ has $\int_0^T E\xi\,dt = 0$ for every shape ξ that vanishes at the ends, then $E(t) = 0$ at every time. *Proof.* Suppose $E(t_0) > 0$ at some time t_0 between 0 and T. Because E is continuous, it stays positive on a small interval $t_0 - w < t < t_0 + w$ (if it were zero or negative arbitrarily close to t_0, its values there would not approach $E(t_0) > 0$). Take a **bump**: a smooth shape that is positive on that interval and zero outside, for example $\xi = \cos^2(\pi(t-t_0)/(2w))$ inside and 0 outside. Then $E\xi$ is positive inside the interval and zero outside, so $\int_0^T E\xi\,dt > 0$, which contradicts the assumption. The case $E(t_0) < 0$ is the same with every sign reversed. So $E(t_0) = 0$ for every t_0. □

The Euler-Lagrange equation. Putting the three lines and the lemma together: the true path satisfies

$$\frac{\partial L}{\partial q} - \frac{d}{dt}\frac{\partial L}{\partial \dot{q}} = 0$$

at every time (PROVED, from the principle of stationary action). For the oscillator, $\partial L/\partial q = -\omega^2 q$ and $\partial L/\partial \dot q = \dot q$, so $E = -\omega^2 q - \ddot q$ and the equation is $\ddot q = -\omega^2 q$: Newton's law for the spring. The true path of our example satisfies it; the line has $\ddot q = 0$ and so $E = -t$; the parabola has $\ddot q = 2$ and so $E = -2 - t^2$. Notebook 07d computes these three functions with a function `euler_lagrange` of its own and with sympy's `euler_equations` (In [5]) and checks that the first variation of every wrong path equals $\int_0^1 E\xi_n\,dt$ (for example, for the line and $n = 1$: $\int_0^1 (-t)\sin\pi t\,dt = -1/\pi$, the value of Section 7.2).

The boundary term, seen. If the shape does not vanish at the end, the boundary term of Line 2 stays. For the oscillator $\partial L/\partial \dot q = \dot q$, so $S_1 = \int_0^1 E\xi\,dt + [\dot q\,\xi]_0^1$. Take the line and the shape $\xi = t$, which is 0 at $t = 0$ but 1 at $t = 1$. By the definition, $S_1 = \int_0^1 (\dot q\dot\xi - q\xi)\,dt = \int_0^1 (1 - t^2)\,dt = 1 - \frac13 = \frac23$. The integral part is $\int_0^1 (-t)\,t\,dt = -\frac13$, and the boundary term is $\dot q(1)\xi(1) - \dot q(0)\xi(0) = 1\cdot 1 - 1\cdot 0 = 1$. Indeed $-\frac13 + 1 = \frac23$ (Notebook 07d prints these three numbers in In [5]; it does the same for the parabola: $\frac34 = -\frac54 + 2$).

The lemma made visible with narrow bumps. The ratio $\int E\xi\,dt / \int \xi\,dt$ is an **average** of E over the bump. For a bump of half-width w centred at t_0 it tends to $E(t_0)$ as w shrinks. For the parabola, whose $E(t) = -2 - t^2$ is a polynomial of degree 2, the error of the average can be computed exactly. Write $t = t_0 + s$:

$$E(t_0 + s) = E(t_0) + E'(t_0)\,s + \tfrac12 E''(t_0)\,s^2$$

(Taylor's formula, Chapter 2, which is exact for a polynomial of degree 2; here $E' = -2t_0$ and $E'' = -2$). The bump is symmetric around t_0, so the average of s over it is 0 (the contributions of s and $-s$ cancel), and

$$\text{average of } E - E(t_0) = \tfrac12 E'' \cdot (\text{average of } s^2) = -(\text{average of } s^2).$$

With $s = wu$, where u runs from -1 to 1, the average of s^2 is w^2 times the number

$$c = \frac{\int_{-1}^1 u^2\cos^2(\pi u/2)\,du}{\int_{-1}^1 \cos^2(\pi u/2)\,du}.$$

Using $\cos^2(\pi u/2) = \frac12(1 + \cos\pi u)$ (the double-angle formula), the denominator is $\int_{-1}^1 \frac12(1 + \cos\pi u)\,du = 1$ (the cosine integrates to $[\sin\pi u/\pi]_{-1}^1 = 0$). The numerator is

$$\tfrac12\int_{-1}^1 u^2\,du + \tfrac12\int_{-1}^1 u^2\cos\pi u\,du = \tfrac13 + \tfrac12\cdot\Big(-\frac{4}{\pi^2}\Big),$$

where the last integral follows from two integrations by parts: $\int_{-1}^1 u^2\cos\pi u\,du = -\frac{2}{\pi}\int_{-1}^1 u\sin\pi u\,du$ and $\int_{-1}^1 u\sin\pi u\,du = \frac{2}{\pi}$. So

$$\text{average of } E - E(t_0) = -\Big(\frac13 - \frac{2}{\pi^2}\Big)w^2 = -0.130691\,w^2,$$

independent of t_0 and exactly proportional to w^2: halving w divides the error by 4 (PROVED here). Of these steps only the replacement of $\frac12 E''$ by -1 used the parabola's $E'' = -2$: for any polynomial

E of degree 2 the same steps give the error $\frac{1}{2}E''(\frac{1}{3}-\frac{2}{\pi^2})w^2$. For the parabola and $w=0.2$ the error is $-0.130691\times 0.04=-5.228\times 10^{-3}$, the number that Notebook 07d computes numerically for all three centres $t_0=0.3,0.5,0.7$, with the ratio 4.0000 between successive half-widths (In [7], Figure 07d.3; COMPUTED with the trapezoidal rule on 200001 points, whose own error is far below the printed digits).

The action on a grid. A computer stores a path as its values $q_0,q_1,\dots,q_N$ at the **grid** times $t_n=nh$, $h=T/N$, and replaces the integral by a sum. With the velocity of each step written as the difference quotient $(q_{n+1}-q_n)/h$ and the potential energy averaged over the two ends of the step,

$$S_N=\sum_{n=0}^{N-1} h\Big[\frac{1}{2}\Big(\frac{q_{n+1}-q_n}{h}\Big)^2-\frac{\omega^2}{4}(q_n^2+q_{n+1}^2)\Big].$$

An inner value q_n $(0<n<N)$ appears in two terms of the sum: the step that ends at t_n (number $n-1$) and the step that starts there (number n). Differentiating with respect to q_n:

$$\frac{\partial S_N}{\partial q_n}=h\Big[\frac{q_n-q_{n-1}}{h^2}-\frac{q_{n+1}-q_n}{h^2}-\frac{\omega^2}{2}q_n-\frac{\omega^2}{2}q_n\Big]$$

(the chain rule on the two squares: $\frac{d}{dq_n}\frac{1}{2}\big(\frac{q_n-q_{n-1}}{h}\big)^2=\frac{q_n-q_{n-1}}{h}\cdot\frac{1}{h}$ and $\frac{d}{dq_n}\frac{1}{2}\big(\frac{q_{n+1}-q_n}{h}\big)^2=\frac{q_{n+1}-q_n}{h}\cdot(-\frac{1}{h})$; and $\frac{d}{dq_n}\frac{\omega^2}{4}q_n^2=\frac{\omega^2}{2}q_n$, once from each step);

$$=h\Big[-\frac{q_{n+1}-2q_n+q_{n-1}}{h^2}-\omega^2 q_n\Big]$$

(the terms collected). The bracket is $E=-\ddot q-\omega^2 q$ with $\ddot q$ replaced by the **second difference quotient** $(q_{n+1}-2q_n+q_{n-1})/h^2$. So "the action on the grid is stationary" means "the grid version of the Euler-Lagrange equation holds at every inner point" (PROVED; Notebook 07d checks it with sympy for $N=5$, In [8]). The second difference quotient differs from $\ddot q$ by a term of size h^2: adding the Taylor series $q(t\pm h)=q\pm h\dot q+\frac{1}{2}h^2\ddot q\pm\frac{1}{6}h^3q^{(3)}+\frac{1}{24}h^4q^{(4)}+\dots$ (Chapter 2) the odd powers cancel and $\big(q(t+h)-2q(t)+q(t-h)\big)/h^2=\ddot q+\frac{1}{12}h^2q^{(4)}+\dots$. Accordingly, the path that makes the grid action stationary approaches the true path with an error proportional to h^2: Notebook 07d solves the grid equations for $N=4,8,\dots,256$ and measures the largest errors 4.089×10^{-4} $(N=4)$ down to 1.008×10^{-7} $(N=256)$ and the observed orders 2.007, 1.978, 2.001, 2.000, 2.000, 2.000 (In [9], Figure 07d.4; COMPUTED).

7.4 Energy, total derivatives and first-order Lagrangians

The energy. For a Lagrangian $L(q,\dot q)$ that does not contain the time explicitly, the **energy** is

$$H=\dot q\,\frac{\partial L}{\partial \dot q}-L.$$

For the oscillator $H=\dot q\cdot\dot q-(\frac{1}{2}\dot q^2-\frac{1}{2}\omega^2q^2)=\frac{1}{2}\dot q^2+\frac{1}{2}\omega^2q^2$, kinetic plus potential energy. Its time derivative along any path, line by line:

$$\frac{dH}{dt} = \ddot{q}\,\dot{q} + \omega^2 q\,\dot{q}$$

(the chain rule: the derivative of $\frac{1}{2}\dot{q}^2$ is $\dot{q}\ddot{q}$, that of $\frac{1}{2}\omega^2 q^2$ is $\omega^2 q\dot{q}$);

$$= \dot{q}\,(\ddot{q} + \omega^2 q) = -\dot{q}\,E$$

(the common factor $\dot{q}$ taken out; then $E = -\ddot{q} - \omega^2 q$). So the energy is constant on every solution of $E = 0$, and it changes on a path where $E \neq 0$ and $\dot{q} \neq 0$ (PROVED; Notebook 07d checks the identity for a general path, In [10]). On the true path, $\dot{q} = \cos t/\sin 1$, so $H = \frac{1}{2}(\cos^2 t + \sin^2 t)/\sin^2 1 = 1/(2\sin^2 1) = 0.706141$, constant; on the line $H = \frac{1}{2} + \frac{1}{2}t^2$ with $dH/dt = t$; on the parabola $H = 2t^2 + \frac{1}{2}t^4$ with $dH/dt = 4t + 2t^3 = 2t(t^2 + 2)$ (all printed by In [10]; Figure 07d.5).

A total derivative changes no equation. Let $F(q, t)$ be any smooth function and add its **total derivative** along the path to the Lagrangian:

$$L' = L + \frac{d}{dt}F(q(t), t) = L + \frac{\partial F}{\partial q}\,\dot{q} + \frac{\partial F}{\partial t}$$

(the chain rule for a function of two variables, both of which change with t). Two proofs that L' has the same Euler-Lagrange equation as L:

- *By the action.* The action changes by $\int_0^T \frac{dF}{dt}dt = F(q(T), T) - F(q(0), 0)$ (the fundamental theorem of calculus), which is the same number for every path with the given end values. A change that is the same for every path cannot change which path is stationary.
- *By the expression.* For $G = \frac{dF}{dt} = F_q\dot{q} + F_t$ (subscripts denote partial derivatives): $\partial G/\partial q = F_{qq}\dot{q} + F_{qt}$ and $\partial G/\partial\dot{q} = F_q$, whose time derivative along the path is $F_{qq}\dot{q} + F_{qt}$. The difference is 0, because the order of two partial derivatives does not matter ($F_{tq} = F_{qt}$, Chapter 2). So G contributes nothing to E.

In particular a Lagrangian that is ONLY a total derivative, such as $\frac{d}{dt}(q^2) = 2q\dot{q}$, has the Euler-Lagrange expression $2\dot{q} - \frac{d}{dt}(2q) = 0$ for every path: it gives no equation at all (PROVED; Notebook 07d checks both statements with $F = tq^3$ and finds that the action changes by exactly 1 for each of the three paths, In [11]). This innocent fact decides, in Section 7.28, why the author's real Majorana-type Lagrangian describes nothing for anticommuting fields.

First-order Lagrangians. The Lagrangians of the two fields of this book contain the derivatives only to the first power. Two small examples show what such Lagrangians do.

Example A: two real variables. $L_A = \frac{1}{2}(q_0\dot{q}_1 - q_1\dot{q}_0) - \frac{1}{2}\omega(q_0^2 + q_1^2)$. With two variables there are two Euler-Lagrange expressions, one for each. For q_0: $\partial L_A/\partial q_0 = \frac{1}{2}\dot{q}_1 - \omega q_0$ and $\partial L_A/\partial\dot{q}_0 = -\frac{1}{2}q_1$, whose time derivative is $-\frac{1}{2}\dot{q}_1$; so

$$E_0 = \tfrac{1}{2}\dot{q}_1 - \omega q_0 - \big(-\tfrac{1}{2}\dot{q}_1\big) = \dot{q}_1 - \omega q_0.$$

For q_1: $\partial L_A/\partial q_1 = -\frac{1}{2}\dot{q}_0 - \omega q_1$ and $\partial L_A/\partial\dot{q}_1 = \frac{1}{2}q_0$, so $E_1 = -\frac{1}{2}\dot{q}_0 - \omega q_1 - \frac{1}{2}\dot{q}_0 = -\dot{q}_0 - \omega q_1$. The equations $\dot{q}_1 = \omega q_0$, $\dot{q}_0 = -\omega q_1$ are of FIRST order: the starting values alone fix the motion

(no starting velocity is needed). For $q_0(0) = 1$, $q_1(0) = 0$ the solution is $q_0 = \cos\omega t$, $q_1 = \sin\omega t$: indeed $\dot{q}_1 = \omega\cos\omega t = \omega q_0$ and $\dot{q}_0 = -\omega\sin\omega t = -\omega q_1$. The point (q_0, q_1) turns on a circle, counterclockwise.

Example B: one complex variable. Let $\psi = (q_0 + iq_1)/\sqrt{2}$, with the **complex conjugate** $\psi^* = (q_0 - iq_1)/\sqrt{2}$, and

$$L_B = \frac{i}{2}(\psi^*\dot{\psi} - \dot{\psi}^*\psi) - \omega\,\psi^*\psi.$$

In real variables: $\psi^*\psi = \frac{1}{2}(q_0 - iq_1)(q_0 + iq_1) = \frac{1}{2}(q_0^2 + q_1^2)$, and $\psi^*\dot{\psi} - \dot{\psi}^*\psi = \frac{1}{2}\big[(q_0 - iq_1)(\dot{q}_0 + i\dot{q}_1) - (\dot{q}_0 - i\dot{q}_1)(q_0 + iq_1)\big] = \frac{1}{2}\big[2iq_0\dot{q}_1 - 2iq_1\dot{q}_0\big] = i(q_0\dot{q}_1 - q_1\dot{q}_0)$ (multiply out; the terms $q_0\dot{q}_0$ and $q_1\dot{q}_1$ cancel). So

$$L_B = \tfrac{i}{2}\cdot i(q_0\dot{q}_1 - q_1\dot{q}_0) - \tfrac{1}{2}\omega(q_0^2 + q_1^2) = \tfrac{1}{2}(q_1\dot{q}_0 - q_0\dot{q}_1) - \tfrac{1}{2}\omega(q_0^2 + q_1^2)\,:$$

Example A with the sign of the kinetic term reversed (because $i\cdot i = -1$). It is a real Lagrangian, although it is written with complex numbers.

Varying ψ and ψ^* as if they were independent. The pair (q_0, q_1) and the pair (ψ, ψ^*) determine each other ($q_0 = (\psi + \psi^*)/\sqrt{2}$, $q_1 = (\psi - \psi^*)/(i\sqrt{2})$): the change of variables is linear and invertible. So one may use ψ and ψ^* as the two variables of the Lagrangian, and the Euler-Lagrange expressions combine in the same way. By the chain rule, $\partial/\partial\psi^* = \frac{\partial q_0}{\partial\psi^*}\partial/\partial q_0 + \frac{\partial q_1}{\partial\psi^*}\partial/\partial q_1 = \frac{1}{\sqrt{2}}(\partial/\partial q_0 + i\,\partial/\partial q_1)$, and therefore

$$E_{\psi^*} = \frac{E_{q_0} + iE_{q_1}}{\sqrt{2}}.$$

Varying ψ^* directly: $\partial L_B/\partial\psi^* = \frac{i}{2}\dot{\psi} - \omega\psi$ and $\partial L_B/\partial\dot{\psi}^* = -\frac{i}{2}\psi$, whose time derivative is $-\frac{i}{2}\dot{\psi}$; so

$$E_{\psi^*} = \tfrac{i}{2}\dot{\psi} - \omega\psi + \tfrac{i}{2}\dot{\psi} = i\dot{\psi} - \omega\psi.$$

The field equation $i\dot{\psi} = \omega\psi$ has the solution $\psi(t) = e^{-i\omega t}\psi(0)$ (the derivative of $e^{-i\omega t}$ is $-i\omega e^{-i\omega t}$, and $i\cdot(-i\omega) = \omega$): the point turns clockwise, with $|\psi|^2 = \frac{1}{2}(q_0^2 + q_1^2)$ constant (PROVED; Notebook 07d checks every statement of the two examples with ω as a symbol, In [12], and draws them in Figure 07d.6). The Lagrangians of the two fields of this book have exactly this structure: ψ becomes the column Ψ of 16 components, ψ^* becomes the row $\bar{\Psi} = \Psi^\dagger C$ (Section 7.19), and ω becomes a matrix of derivatives.

7.5 Fields: one derivative term per coordinate, and what an extra time does

A field is a function of several coordinates, for example $\phi(x_1, x_4)$ of a 3-space coordinate x_1 and the time x_4. Its Lagrangian is a function $\mathcal{L}(\phi, \partial_1\phi, \partial_4\phi)$ of the value and of the partial derivatives $\partial_\mu\phi = \partial\phi/\partial x_\mu$, called a **Lagrangian density**, and the action is its integral over all coordinates of a region. The shapes $\xi(x_1, x_4)$ now vanish on the boundary of the region. Line 1 of Section 7.3 now has one term $\frac{\partial\mathcal{L}}{\partial(\partial_\mu\phi)}\partial_\mu\xi$ for each coordinate; in Line 2 each of them is integrated by parts along its own coordinate (the other coordinates held fixed), and each boundary term vanishes because ξ

vanishes on the boundary; the fundamental lemma works with bumps in several variables in the same way. The result is the Euler-Lagrange expression of a field,

$$E = \frac{\partial \mathcal{L}}{\partial \phi} - \sum_{\mu} \frac{\partial}{\partial x_\mu} \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi)},$$

with one derivative term for each coordinate, and the field equation $E = 0$ at every point (PROVED, by the same three lines and the lemma).

A field of one space direction and time. In the flat version of the author's signature, $\eta_{11} = +1$ and $\eta_{44} = -1$, the Lagrangian density of a field of mass m is

$$\mathcal{L} = -\tfrac{1}{2}(\eta^{11}(\partial_1\phi)^2 + \eta^{44}(\partial_4\phi)^2) - \tfrac{1}{2}m^2\phi^2 = \tfrac{1}{2}(\partial_4\phi)^2 - \tfrac{1}{2}(\partial_1\phi)^2 - \tfrac{1}{2}m^2\phi^2$$

(the numbers η^{aa} are equal to η_{aa}, ± 1): kinetic energy $\frac{1}{2}(\partial_4\phi)^2$ minus a gradient energy along x_1 and a potential energy. The Euler-Lagrange expression, line by line:

$$E = \frac{\partial \mathcal{L}}{\partial \phi} - \partial_1 \frac{\partial \mathcal{L}}{\partial (\partial_1 \phi)} - \partial_4 \frac{\partial \mathcal{L}}{\partial (\partial_4 \phi)}$$

(the formula with its two coordinates);

$$= -m^2\phi - \partial_1(-\partial_1\phi) - \partial_4(\partial_4\phi)$$

(the three partial derivatives of $\mathcal{L}$, each with the other two arguments held fixed);

$$= \partial_1^2\phi - \partial_4^2\phi - m^2\phi$$

(two minus signs give a plus). So $\partial_4^2\phi = \partial_1^2\phi - m^2\phi$: the wave equation with a mass, called the **Klein-Gordon equation**. A **plane wave** $\phi = \cos(kx_1)\cos(\omega x_4)$, with **wave number** k and angular frequency ω, has $\partial_1^2\phi = -k^2\phi$ and $\partial_4^2\phi = -\omega^2\phi$, so $E = (-k^2 + \omega^2 - m^2)\phi$, which vanishes exactly when

$$\omega^2 = m^2 + k^2,$$

the **dispersion relation**: the wave oscillates in time for every k (PROVED; Notebook 07d, In [14]).

A field of one extra time and time. Replace x_1 by the extra time x_5. The author's signature makes x_5 time-like, $\eta_{55} = -1$, and the same recipe gives

$$\mathcal{L} = \tfrac{1}{2}(\partial_4\phi)^2 + \tfrac{1}{2}(\partial_5\phi)^2 - \tfrac{1}{2}m^2\phi^2, \qquad E = -\partial_5^2\phi - \partial_4^2\phi - m^2\phi.$$

The only change is the sign of the x_5 term. Try $\phi = \cos(kx_5)\,P(x_4)$. Then $\partial_5^2\phi = -k^2\phi$ and $E = \cos(kx_5)(k^2P - P'' - m^2P)$, so the field equation becomes

$$P'' = (k^2 - m^2)\,P.$$

For $k < m$ the solutions oscillate. For $k > m$ they are $\cosh(\kappa x_4)$ and $\sinh(\kappa x_4)$ with

$$\kappa = \sqrt{k^2 - m^2}$$

(the second derivative of $\cosh(\kappa x_4)$ is $\kappa^2 \cosh(\kappa x_4)$): they GROW exponentially, and the **growth rate** κ becomes as large as we like when k grows. A wave along a space direction raises ω^2 above m^2; a wave along an extra time lowers it to $m^2 - k^2$, below zero when $k > m$ (PROVED; Notebook 07d, In [15], Figures 07d.7 and 07d.8).

The same growth for the 16-component fields. The fields of this book obey a first-order equation $\gamma^{(a)}\partial_a \Psi = m\Psi$ in flat space (Section 7.21). Multiplying it by the same operator once more turns it into a second-order equation for every component, because of the Clifford relation of the author's gamma matrices (Chapter 4), $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}$. For constant numbers k_a it gives, line by line,

$$\Big(\sum_a k_a \gamma^{(a)}\Big)^2 = \sum_{a,b} k_a k_b\, \gamma^{(a)}\gamma^{(b)} = \tfrac{1}{2}\sum_{a,b} k_a k_b (\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}) = \sum_a \eta^{aa} k_a^2\, I_{16}$$

(multiply out the square of a sum; then use that the double sum does not change when the names a and b are exchanged, so it equals half the sum of itself and its exchanged form; then the Clifford relation, which leaves only $a = b$). Written out: $(k_1^2 + k_2^2 + k_3^2 - k_4^2 - k_5^2 - k_6^2 - k_7^2 + k_0^2)\, I_{16}$, where I_{16} is the 16×16 identity matrix (PROVED; Notebook 07d checks it exactly with the author's gammas, In [15]; it reproduces `Revision/theory/reports/python-field-theory.json`, check `clifford_relations`). The Revision record finds for a plane wave of the 16-component field with an extra-time momentum $k_5 = K$ the growth rate $\sqrt{K^2 - k_1^2 - k_2^2 - k_3^2 - k_0^2 - m^2}$, which has no upper bound as K grows (`Revision/theory/reports/python-scope.json`, check `extra_time_growth_rates_unbounded`); for a momentum along x_5 alone it is $\sqrt{K^2 - m^2}$, the κ above (Notebook 07d reads the formula from the record and checks this, In [15]). What this unbounded growth means for the field equations of the book (no well-posed initial-value problem for data that depend on the extra times) is the subject of Chapter 8.

7.6 Example: Notebook 07d derives the Euler-Lagrange equation

Notebook 07d puts Sections 7.2 to 7.5 to work. It computes exactly, with sympy, the action of the true path and of the two wrong paths and of their variations, and shows that only the true path has a zero first variation; it checks the formula for S_2 and the change from minimum to saddle at $T = \pi/\omega$; it computes the Euler-Lagrange expression with a function of its own and with sympy's, checks the integration by parts with and without the boundary term, the fundamental lemma with narrow bumps, the action on a grid and its second-order convergence, the energy, the total derivative, the two first-order examples, and the field equations along a space direction and along an extra time, where it reproduces the growth rate of the Revision record. It draws eight figures and ends with the line ALL 30 CHECKS PASSED (notebook 07d).

7.7 How to run Notebook 07d

Step 1. What this notebook does and what it needs.

Notebook 07d (The action principle and the Euler-Lagrange equation) is the file `Revision/textbook/notebooks/07d_action_principle.ipynb` of the repository Dirac_claude. It shows, for a reader who knows one-variable calculus, where the Euler-Lagrange equation comes from: it computes exactly the action of the true path and of two wrong paths of an oscillator and of their small variations, shows that only the true path makes the action stationary, checks the integration by parts, the fundamental lemma with narrow bumps, the action on a grid of times and its second-order convergence, the conserved energy, that a total derivative changes no equation, the first-order Lagrangians of a real pair and of one complex variable, and the field equation of a field of a space direction or of an extra time with time; it reproduces the growth rate of the Revision record for an extra-time momentum, and draws eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 07d_action_principle.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 07d_action_principle.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 07d_action_principle.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/07d.captions.json`
- `Revision/textbook/figures/07d_1_action_versus_epsilon.png`
- `Revision/textbook/figures/07d_2_paths_and_residuals.png`
- `Revision/textbook/figures/07d_3_bump_lemma.png`
- `Revision/textbook/figures/07d_4_action_on_a_grid.png`
- `Revision/textbook/figures/07d_5_energy_along_paths.png`
- `Revision/textbook/figures/07d_6_first_order_rotation.png`
- `Revision/textbook/figures/07d_7_space_and_extra_time.png`
- `Revision/textbook/figures/07d_8_dispersion.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of this notebook exist
ALL 30 CHECKS PASSED (notebook 07d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/07d_action_principle.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 07d_action_principle.ipynb
python -m nbconvert --execute --inplace 07d_action_principle.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory/reports Revision/algebra
```

7.8 Notebook 07d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/07d_action_principle.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Notebooks 07a, 07b and 07c USE the Euler-Lagrange equation: they take a Lagrangian
and compute the expression $\partial L/\partial q - \frac{d}{dt}\,\partial L /
\partial\dot q$. This notebook shows where that expression comes from, with nothing
more than one-variable calculus and a computer that checks every step. It

- computes, exactly, the **action** (the time integral of the Lagrangian) of the
  true motion of an oscillator and of two wrong motions with the same end points,
  and of every motion changed by a small amount $\epsilon$ times a fixed shape;
  only the true motion has an action whose slope in $\epsilon$ is zero;
- shows that the true motion makes the action a minimum for short times and only
  stationary (a saddle) for long times;
- checks the integration by parts that turns the slope into the integral of the
  **Euler-Lagrange expression** times the shape, and shows the boundary term that
  appears when the shape does not vanish at the ends;
- illustrates the **fundamental lemma** with narrow bumps: a function whose
  integral against every bump is zero must be zero;
- writes the action on a grid of times, as a computer would, shows that its
  derivatives are the Euler-Lagrange expression on the grid, solves the grid
  equations and measures the error, which falls like the square of the step;
- checks that the energy is constant on the true motion and only there;
- checks that adding a total derivative to a Lagrangian changes no equation;
- derives the equations of two **first-order** Lagrangians, of the kind the fields
  of this book have: two real variables, and one complex variable $\psi$ varied
  together with its conjugate $\psi^*$ as if they were independent;
- derives the field equation of a field of one space coordinate and time, and of
  a field of one EXTRA time and time, and shows that the extra time turns
  oscillation into exponential growth, with the growth rate of the Revision record.

Every result is checked by a line that starts with PASS; the last line counts the
checks. Eight figures are drawn and saved.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 07d (The action principle and the Euler-Lagrange equation) is the file
‘Revision/textbook/notebooks/07d_action_principle.ipynb‘ of the repository Dirac_claude.
```

It shows, for a reader who knows one-variable calculus, where the Euler-Lagrange equation comes from: it computes exactly the action of the true path and of two wrong paths of an oscillator and of their small variations, shows that only the true path makes the action stationary, checks the integration by parts, the fundamental lemma with narrow bumps, the action on a grid of times and its second-order convergence, the conserved energy, that a total derivative changes no equation, the first-order Lagrangians of a real pair and of one complex variable, and the field equation of a field of a space direction or of an extra time with time; it reproduces the growth rate of the Revision record for an extra-time momentum, and draws eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
```

```
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 07d_action_principle.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
```

```
    jupyter nbconvert --to notebook --execute --inplace 07d_action_principle.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 07d_action_principle.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/07d.captions.json‘
- ‘Revision/textbook/figures/07d_1_action_versus_epsilon.png‘
- ‘Revision/textbook/figures/07d_2_paths_and_residuals.png‘
- ‘Revision/textbook/figures/07d_3_bump_lemma.png‘
- ‘Revision/textbook/figures/07d_4_action_on_a_grid.png‘
- ‘Revision/textbook/figures/07d_5_energy_along_paths.png‘
- ‘Revision/textbook/figures/07d_6_first_order_rotation.png‘
- ‘Revision/textbook/figures/07d_7_space_and_extra_time.png‘
- ‘Revision/textbook/figures/07d_8_dispersion.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS all 8 figure files of this notebook exist
    ALL 30 CHECKS PASSED (notebook 07d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file

  ‘Revision/textbook/notebooks/07d_action_principle.ipynb‘ inside the folder
  Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 07d_action_principle.ipynb
      python -m nbconvert --execute --inplace 07d_action_principle.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision
  record files of your copy of the repository differ from the committed ones; restore
  them with the command below (run in the repository folder) and run the notebook again.

      git restore Revision/theory/reports Revision/algebra

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 07d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 07d (The action principle and the Euler-Lagrange equation) is the file
# Revision/textbook/notebooks/07d_action_principle.ipynb of the repository Dirac_claude.
# It shows, for a reader who knows one-variable calculus, where the Euler-Lagrange

# of the Revision record for an extra-time momentum, and draws eight teaching plots. It
# needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
```

```
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
```

```
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 07d_action_principle.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 07d_action_principle.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 07d_action_principle.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/07d.captions.json
```

```
# - Revision/textbook/figures/07d_1_action_versus_epsilon.png
# - Revision/textbook/figures/07d_2_paths_and_residuals.png
# - Revision/textbook/figures/07d_3_bump_lemma.png
# - Revision/textbook/figures/07d_4_action_on_a_grid.png
# - Revision/textbook/figures/07d_5_energy_along_paths.png
# - Revision/textbook/figures/07d_6_first_order_rotation.png
# - Revision/textbook/figures/07d_7_space_and_extra_time.png
# - Revision/textbook/figures/07d_8_dispersion.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 8 figure files of this notebook exist
#     ALL 30 CHECKS PASSED (notebook 07d)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/07d_action_principle.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 07d_action_principle.ipynb
```

```
#     python -m nbconvert --execute --inplace 07d_action_principle.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision
#   record files of your copy of the repository differ from the committed ones; restore
#   them with the command below (run in the repository folder) and run the notebook
#   again.
#     git restore Revision/theory/reports Revision/algebra
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Path** (or motion): a function $q(t)$ that gives the position $q$ of a particle
  on a line at every time $t$ between a start time and an end time. Here the times
  run from $0$ to $T$. Its **velocity** is $\dot q = dq/dt$, its **acceleration**
  $\ddot q = d^2q/dt^2$.
- **Lagrangian** $L(q, \dot q)$: a function of the position and the velocity; for
  the oscillator of this notebook $L = \frac12\dot q^2 - \frac12\omega^2q^2$, the
  kinetic energy minus the potential energy (mass 1, angular frequency $\omega$).
- **Action** $S[q] = \int_0^T L(q(t), \dot q(t))\,dt$: one number for a whole
  path. The square brackets say that $S$ depends on the whole function $q$; such a
  rule (a function in, a number out) is called a **functional**.
- **Variation**: a shape $\xi(t)$ with $\xi(0) = \xi(T) = 0$; the varied path is
  $q + \epsilon\xi$ with a small number $\epsilon$. The **first variation** is the
  slope $dS[q + \epsilon\xi]/d\epsilon$ at $\epsilon = 0$.
- **Stationary path**: a path whose first variation is zero for every variation.
```

  The **principle of stationary action** says that the true motion is stationary.
- **Euler-Lagrange expression** $E(t) = \partial L/\partial q - \frac{d}{dt}\,\partial L/\partial\dot q$, and the **Euler-Lagrange equation** $E = 0$. In $\partial L/\partial q$ the velocity is held fixed, in $\partial L/\partial\dot q$ the position.
- **Integration by parts**: the product rule $\frac{d}{dt}(fg) = \dot f g + f\dot g$ integrated from 0 to T: $\int_0^T f\dot g\,dt = [fg]_0^T - \int_0^T \dot f g\,dt$, where $[fg]_0^T = f(T)g(T) - f(0)g(0)$ is the **boundary term**.
- **Bump**: a smooth shape that is positive on a small interval and zero outside.
- **Grid**: the equally spaced times $t_n = nh$, $n = 0, 1, \dots, N$, with step $h = T/N$. **Order of convergence**: the power p in error $\approx$ constant $\times\,h^p$.
- **Energy** $H = \dot q\,\partial L/\partial\dot q - L$; for the oscillator $H = \frac12\dot q^2 + \frac12\omega^2q^2$.
- **Total derivative**: $\frac{d}{dt}F(q(t), t)$ for some function F.
- **First-order Lagrangian**: a Lagrangian that contains the velocities only to the first power, like the Lagrangians of the fields of this book.
- **Field**: a function of several coordinates, here $\phi(x_1, x_4)$ or $\phi(x_5, x_4)$, with the author's names: x_1 a direction of 3-space, x_4 the time, x_5 one of the three extra times. **Lagrangian density**: the Lagrangian of a field, integrated over all its coordinates.
- **Plane wave**: a field such as $\cos(kx_1)\cos(\omega x_4)$, with **wave number** k and angular frequency ω. **Dispersion relation**: the equation that links ω to k.

Text cell:

```
## 4. The physical and mathematical situation

**The principle.** Among all paths with the same end points, $q(0) = q_A$ and
$q(T) = q_B$, the particle follows one for which the action does not change to
first order when the path is changed a little: for every variation $\xi$,

$$\frac{d}{d\epsilon}S[q + \epsilon\xi]\Big|_{\epsilon = 0} = 0 .$$

**From the principle to the equation, line by line.**

$$\frac{d}{d\epsilon}S[q + \epsilon\xi]\Big|_{\epsilon=0} = \int_0^T\Big(
\frac{\partial L}{\partial q}\,\xi + \frac{\partial L}{\partial\dot q}\,\dot\xi
\Big)dt$$

This first line differentiates under the integral sign with the chain rule: $L$
depends on $\epsilon$ through its first argument $q + \epsilon\xi$ (derivative
$\xi$) and through its second argument $\dot q + \epsilon\dot\xi$ (derivative
$\dot\xi$).

$$= \int_0^T\frac{\partial L}{\partial q}\,\xi\,dt + \Big[\frac{\partial L}
{\partial\dot q}\,\xi\Big]_0^T - \int_0^T\frac{d}{dt}\Big(\frac{\partial L}
{\partial\dot q}\Big)\xi\,dt$$

The second line integrates the second term by parts with $f = \partial L/\partial
\dot q$ and $g = \xi$.
```

```
$$= \int_0^T E(t)\,\xi(t)\,dt,\qquad E = \frac{\partial L}{\partial q} -
\frac{d}{dt}\frac{\partial L}{\partial\dot q} .$$

The third line drops the boundary term, which is zero because $\xi(0) = \xi(T) =
0$, and collects the two integrals. Finally the **fundamental lemma**: if a
continuous $E$ had $E(t_0) > 0$ at some time $t_0$, it would be positive on a small
interval around $t_0$, and a bump $\xi$ on that interval would give $\int E\xi\,dt
> 0$; the same with signs reversed for $E(t_0) < 0$. So the true path satisfies
the **Euler-Lagrange equation** $E(t) = 0$ at every time. For the oscillator,
$\partial L/\partial q = -\omega^2q$ and $\partial L/\partial\dot q = \dot q$, so
$E = -\omega^2q - \ddot q$ and the equation is $\ddot q = -\omega^2q$.

**The example of this notebook.** $\omega = 1$, $T = 1$, $q(0) = 0$, $q(1) = 1$.
The true path is $q(t) = \sin t/\sin 1$ (it solves $\ddot q = -q$ and has the right
end values). Two wrong paths with the same end values: the straight line $q = t$
and the parabola $q = t^2$. Variations: $\xi_n(t) = \sin(n\pi t)$, $n = 1, 2, 3$,
which vanish at $t = 0$ and $t = 1$.

**Fields.** For a field $\phi$ of several coordinates the action is the integral of
a Lagrangian density over all of them, the variation $\xi$ vanishes on the
boundary of the region, and the same three lines give one derivative term for each
coordinate: $E = \partial L/\partial\phi - \sum_\mu \frac{\partial}{\partial
x_\mu}\,\partial L/\partial(\partial_\mu\phi)$. This is the expression that
Notebook 07b computes for the 16 components of the fields of this book in the
author's metric (with left derivatives for anticommuting components, Notebook 07a).
```

Text cell:

```
## 5. The action of the true path and of two wrong paths

The next cell imports the packages, wraps the set-up cell's ‘check‘ so that a PASS
line and the line "reproduces ..." that may follow it are printed by one single
‘print‘ call (Jupyter may deliver two separate prints in two pieces, and the
book's tools must see the two lines together), and defines the helper
‘reproduces‘, which makes sure that a Revision report contains a check with the
verdict PASS before a PASS line names it.

Then it computes, with exact computer algebra (sympy), the action of $q +
\epsilon\xi_n$ for each of the three paths and $n = 1, 2, 3$. Since $L$ is a
polynomial of degree 2 in $q$ and $\dot q$, the action is a polynomial of degree 2
in $\epsilon$:

$$S[q + \epsilon\xi] = S_0 + S_1\,\epsilon + S_2\,\epsilon^2 .$$

$S_1$ is the first variation (the slope at $\epsilon = 0$). The cell prints $S_1$
for every path and every $n$, exactly and as a decimal number.
```

In [2]:

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)
```

```
import re  # regular expressions: read a formula from a check's detail text

The next cell checks the two facts the table shows: for the true path the first
variation is exactly zero for all three shapes, for the two wrong paths it is not.
It also checks that the coefficient $S_2$ does not depend on the path: $S_2 =
\int_0^T(\frac12\dot\xi^2 - \frac12\omega^2\xi^2)\,dt$ is the action of the shape
itself, because the terms of $L$ that are quadratic in $\epsilon$ contain only
$\xi$.

## 6. A minimum, or only stationary?

For the shape $\xi_1 = \sin(\pi t/T)$ on an interval of general length $T$, the
coefficient $S_2$ is, line by line,

$$S_2 = \int_0^T\Big(\frac{\pi^2}{2T^2}\cos^2\frac{\pi t}{T} - \frac{\omega^2}{2}
\sin^2\frac{\pi t}{T}\Big)dt = \frac{\pi^2}{2T^2}\cdot\frac{T}{2} - \frac{\omega^2}
{2}\cdot\frac{T}{2} = \frac{T}{4}\Big(\frac{\pi^2}{T^2} - \omega^2\Big).$$

The first equality inserts $\dot\xi_1 = (\pi/T)\cos(\pi t/T)$. The second uses
$\cos^2 x = \frac12(1 + \cos 2x)$ and $\sin^2 x = \frac12(1 - \cos 2x)$: the interval
from 0 to $T$ is one full period of $\cos(2\pi t/T)$, whose integral over it is 0,
so $\cos^2(\pi t/T)$ and $\sin^2(\pi t/T)$ each integrate to $T/2$. The third
collects. So $S_2 > 0$ for $T < \pi/\omega$: then the true path is a MINIMUM of the
action along this direction. For $T > \pi/\omega$ the coefficient is negative: the
true path is still stationary ($S_1 = 0$), but the action is a maximum along
$\xi_1$ and a minimum along faster shapes, a saddle. This is why the principle is
called the principle of STATIONARY action, not of least action. The next cell
checks the formula with $T$ as a symbol, then draws Figure 1.

## 7. The first variation is the integral of $E$ times the shape

The derivation of section 4 says $S_1 = \int_0^1 E\,\xi\,dt$ when $\xi$ vanishes at
both ends, and $S_1 = \int_0^1 E\,\xi\,dt + [\dot q\,\xi]_0^1$ in general (for the
oscillator $\partial L/\partial\dot q = \dot q$). The next cell defines a function
‘euler_lagrange‘ that computes $E$ for any Lagrangian $L(q, \dot q)$ exactly as
the words of section 3 say: it replaces $q(t)$ and $\dot q(t)$ by two plain
symbols, differentiates with respect to each with the other held fixed, puts the
functions back, and differentiates the second result with respect to $t$. It
compares the result with sympy’s own ‘euler_equations‘, prints $E$ for the three
paths ($E = -\ddot q - q$), and checks the formula for $S_1$ for the two wrong
paths, both for the shapes $\xi_n$ and for the shape $\xi = t$, which does NOT
vanish at $t = 1$ and therefore produces the boundary term $\dot q(1)\cdot 1$.
```
