These lines check each step of the proof of Section 9.26: $CP_k = -P_kC$ and P_k symmetric for the three P_k; and, for each witness, $v_1^\dagger C v_1 = 0$, $v_2^\dagger C v_2 = 0$ and $S = 2|v_1^\dagger C v_2|^2$. `observation` tests a further formula, $S = 2\omega^2/V^2$.

```
check(anticommute and symmetric and steps_hold,
      "C P_k = -P_k C, P_k symmetric, v^dagger C v = 0, so S = 2 |v1^dagger C v2|^2")
check(observation,
      "observed: S = 2 omega^2 / V^2 for the three witnesses (unit v1, v2)")
```

The first check confirms the steps of the proof. The second confirms the observation $S = 2\omega^2/V^2$ for these three witnesses ($2 \cdot 16/25 = 1.28$ and $2 \cdot 9/25 = 0.72$); this formula is COMPUTED for three cases and not proved here.

In [13], the numbers of the record.

```
detail = record_entry(A4_WL, "condensate_diagonal_witness_exact")["detail"]
# the frequencies, which the record writes "w = sqrt(M^2 - 9 H^2) = {4, 3, 4}"
freq_text = re.search(r"9 H\^2\) = \{([^}]*)\}", detail).group(1)  # "4, 3, 4"
S_text = re.search(r"S = \{([^}]*)\}", detail).group(1)  # the three S values
record_freq = np.array([float(value) for value in freq_text.split(",")])
record_S = np.array([float(value) for value in S_text.split(",")])
our_freq = np.array([witnesses[pair][0] for pair in WITNESSES])
our_S = np.array([unit_S[pair] for pair in WITNESSES])
```

The record's Wolfram report writes the witnesses' numbers into the detail text of its check `condensate_diagonal_witness_exact`. `re.search(pattern, text)` finds the first place where the pattern matches, and `.group(1)` returns the part inside the first parentheses of the pattern. In the first pattern a backslash makes `^`, `)`, `{` and `}` ordinary characters, and `[^}]*` means "any characters except a closing brace"; so `freq_text` is the text between the braces after `9 H^2) =`, namely `4, 3, 4`, and `S_text` the text between the braces after `S =`. `.split(",")` cuts each text at the commas and `float` turns the pieces into numbers. `our_freq` and `our_S` are the notebook's values in the same order.

```
check(np.abs(our_freq - record_freq).max() < 1e-12
      and recorded(A4_WL, "condensate_diagonal_witness_exact") == "PASS"
      and recorded(A4_PY, "authorT16_condensate_witness") == "PASS",
      f"omega = {freq_text} for the three witnesses, as in the record",
      record=f"{A4_WL}, check condensate_diagonal_witness_exact; {A4_PY}, check "
             "authorT16_condensate_witness")
quotients = record_S / our_S  # S of the record divided by S of unit v1, v2
check(np.abs(quotients / quotients[0] - 1).max() < 1e-9 and np.all(record_S > 0),
      f"S = {S_text} of the record are one common multiple of ours",
      record=f"{A4_WL}, check condensate_diagonal_witness_exact")
report("S of the record divided by S of unit v1, v2 (all three)",
       f"{quotients[0]:.1f}")
```

The frequencies must agree exactly: $\omega = \sqrt{V^2 - 9H^2}$ does not depend on any choice. The values of S cannot agree, because the record builds the witnesses with exact columns v_1, v_2 that are not of length 1, and $S = 2|v_1^\dagger C v_2|^2$ grows with their lengths (multiplying v_1 by a number a and v_2 by b multiplies S by $|a|^2|b|^2$). So the second check divides each recorded S by ours and requires the three quotients to be one and the same number; the record's values are then reproduced up to one common factor, which the cell prints. The factor is not physics: it is the product of the squared lengths of the record's columns, a choice of the record's verifier, and it changes whenever the verifier picks other columns. The Wolfram report `Revision/field_equations_a4/reports/wolfram-a4-report.json` in its version of 2026-10-08 (52 checks), whose verifier builds the columns from the author's gamma matrices, lists $S = 51200, 28800, 51200$; the quotients are $51200/1.28 = 40000$ for the first and the third witness and $28800/0.72 = 40000$ for the second, and the cell prints 40000.0. The version of 2026-10-01 (47 checks) built its columns from another set of 16×16 gamma matrices that obey the same Clifford relations and listed $S = 204800, 115200, 204800$, the common factor 160000 (the record file `Revision/field_equations_a4/README.md` states both): the factor changed with the columns, while the frequencies, $S \neq 0$ and the vanishing of the 15 bilinears did not. The

notebook reads the numbers from the report, so a later version of the report that lists other values of S makes the cell print those values and their quotient instead.

In [14], the heat map of a witness (Figure 09c.3).

```
T_witness = condensate_tensor(witness_columns[(5.0, 1.0)], **POINT)
fig, ax = plt.subplots(figsize=(6.6, 5.6))
picture = heat_map(ax, T_witness, "Witness condensate: $T^\\nu{}_\\mu$", SCALE)
fig.colorbar(picture, ax=ax, label="value (energy per unit volume)", extend="both")
save_figure(fig, "witness_condensate",
            "Heat map of the 64 entries $T^\\nu{}_\\mu$ of the exact witness "
            ...)
check(len(off_diagonal_pairs(T_witness)) == 0 and abs(T_witness[4, 4]) > 0.1,
      "the drawn witness tensor is diagonal with T^x4_x4 = -V S != 0")
```

The witness with $(V, H) = (5, 1)$ is drawn at the same point and with the same colour scale as the generic condensate. **What Figure 09c.3 shows.** All 64 entries, in units of energy per unit volume: only the square (x_4, x_4) is coloured, with $-VS = -5 \cdot 1.28 = -6.40$ (beyond the colour scale, so it has the darkest blue); every other entry is zero, the pressure included ($\lambda = 0$). The student should compare it with Figure 09c.1: this condensate is a perfect fluid at rest. The check confirms that no entry off the diagonal is nonzero.

In [15], the Christoffel symbols along a curved history.

```
x = sp.symbols("x0:8", real=True)  # sympy was imported in section 8
Hs = sp.symbols("H", positive=True)
a4_function = sp.Function("a4")(x[4])
zs = 6 * Hs * x[0]
space_entry = sp.exp(2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
extra_entry = -sp.exp(-2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
g = sp.diag(*([sp.cot(zs) ** 2] + [space_entry] * 3 + [-1] + [extra_entry] * 3))
history = sp.Rational(3, 10) * x[4] + sp.Rational(1, 20) * x[4] ** 2  # a4(x4)
```

The metric with symbols, as in In [13] of Notebook 09a, and the history $a_4 = \frac{3}{10}x_4 + \frac{1}{20}x_4^2$ with exact fractions. It is curved (not linear), increasing for $x_4 > -3$: the extra times deflate at a growing rate $a_4' = 0.3 + 0.1x_4$.

```
christoffel = {}  # (l, i, j) with i <= j -> a numpy function of (x4, x0, H)
for l in range(8):
    for i in range(8):
        for j in range(i, 8):
            value = sp.simplify((sp.diff(g[l, j], x[i]) + sp.diff(g[l, i], x[j])
                                 - sp.diff(g[i, j], x[l])) / (2 * g[l, l]))
            if value != 0:  # put the history in, then make a numpy function
                christoffel[(l, i, j)] = sp.lambdify(
                    (x[4], x[0], Hs), value.subs(a4_function, history).doit(), "numpy")
check(len(christoffel) == 25, "25 nonzero Christoffel symbols (i <= j)")
```

The 25 symbols are computed as in Notebook 09a. Then the history is put in (`.subs(a4_function, history)` replaces $a_4(x_4)$; `.doit()` carries out the derivative a_4' that is now a derivative of a known

function), and `sp.lambdify((x4, x0, H), expression, "numpy")` turns the exact expression into a fast numpy function of the three numbers. The check confirms the count, 25.

In [16], the test condensate, the control and the divergence.

```
m9, lam9, H9 = 1.0, 0.5, 0.25  # the parameters of this section
chi9 = rng.normal(size=16) + 1j * rng.normal(size=16)
chi9 /= np.linalg.norm(chi9)
V9 = m9 + lam9 * (bar(chi9) @ chi9).real  # the effective mass
M_TRUE = -V9 * g4 + 3 * H9 * g4 @ g0  # the true condensate: M^2 = 9 H^2 - V^2
M_CONTROL = -V9 * g4  # without the term 3 H gamma^(x0): M^2 = -V^2
K2_TRUE, K2_CONTROL = 9 * H9 ** 2 - V9 ** 2, -V9 ** 2
```

The test uses $m = 1$, $\lambda = 0.5$, $H = 0.25$ and a new random unit column. The true condensate has the matrix M of Section 9.18; the control leaves out $3H\gamma^{(4)}\gamma^{(0)}$, so its matrix squares to $-V^2$ (the same computation as in Section 9.18 with $H = 0$).

```
def field(M, k2, x4):
    """Phi(x4) and dPhi/dx4 = M Phi(x4) for Phi(0) = chi9 (M^2 = k2)."""
    k = np.sqrt(complex(k2))
    phi = np.cosh(k * x4) * chi9 + np.sinh(k * x4) / k * (M @ chi9)
    return phi, M @ phi

def tensor_at(M, k2, x4, x0):
    phi, d4 = field(M, k2, x4)
    dphi = np.zeros((8, 16), dtype=complex)
    dphi[4] = d4
    return energy_momentum(phi, dphi, m9, lam9, 0.3 * x4 + 0.05 * x4 ** 2,
                           0.3 + 0.1 * x4, 6 * H9 * x0, H9)
```

`field` returns $\Phi(x_4)$ and $\partial_4\Phi = M\Phi$ for either matrix. `tensor_at` returns the 64 entries at the point (x_4, x_0) of the curved history: $a_4 = 0.3x_4 + 0.05x_4^2$, $a_4' = 0.3 + 0.1x_4$ and $z = 6Hx_0$.

```
def divergence(M, k2, x4, x0, h):
    """The eight components of nabla_mu T^mu_nu, with central differences of step h,
    and the size of the tensor (its largest entry)."""
    T = tensor_at(M, k2, x4, x0)
    d4T = (tensor_at(M, k2, x4 + h, x0) - tensor_at(M, k2, x4 - h, x0)) / (2 * h)
    d0T = (tensor_at(M, k2, x4, x0 + h) - tensor_at(M, k2, x4, x0 - h)) / (2 * h)
```

The tensor of a condensate depends on x_4 and x_0 only, so its divergence needs $\partial_4 T$ and $\partial_0 T$. They are replaced by **central finite differences**, $\partial F \approx (F(x+h) - F(x-h))/(2h)$, whose error falls like h^2 as the step h shrinks (the Taylor series: the terms of first and third order of $F(x+h)$ and $F(x-h)$ cancel in the difference, up to the error term $\frac{h^2}{6}F'''$).

```
    G = np.zeros((8, 8, 8))  # G[l, i, j] = Gamma^l_ij
    for (l, i, j), function in christoffel.items():
        G[l, i, j] = G[l, j, i] = function(x4, x0, H9)
```

```
    result = np.zeros(8)
    for nu in range(8):
        result[nu] = (d4T[4, nu] + d0T[0, nu]  # d_mu T^mu_nu (only x4 and x0)
                      + np.einsum("mml,l->", G, T[:, nu])  # Gamma^mu_mu l T^l_nu
                      - np.einsum("lm,ml->", G[:, :, nu], T))  # Gamma^l_mu nu T^mu_l
    return result, np.abs(T).max()

report("effective mass V = m + lambda S of the test condensate", f"{V9:.6f}")
```

`G` is the $8 \times 8 \times 8$ table of all Christoffel symbols at the point (both orders of the lower indices are filled). For each ν the divergence is the formula of Section 9.9: the first sum has only the terms $\partial_4 T^{x_4}{}_\nu$ and $\partial_0 T^{x_0}{}_\nu$; `np.einsum("mml,l->", G, T[:, nu])` is $\sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda} T^\lambda{}_\nu$ (a repeated letter is summed; `->` with nothing after it means "sum everything to one number"), and `np.einsum("lm,ml->", G[:, :, nu], T)` is $\sum_{\lambda,\mu} \Gamma^\lambda{}_{\mu\nu} T^\mu{}_\lambda$. All entries off the diagonal are included. The function returns the eight components and the size of the tensor. The cell prints $V = 0.883522$.

In [17], the divergence as the step shrinks.

```
steps = 0.2 / 2.0 ** np.arange(11)  # 0.2, 0.1, ..., about 0.0002
X4_TEST, X8_TEST = 1.0, 0.5 / (6 * H9)  # x4 = 1 and z = 0.5
true_sizes, control_sizes = [], []
for h in steps:
    div_true, size_true = divergence(M_TRUE, K2_TRUE, X4_TEST, X8_TEST, h)
    div_control, _ = divergence(M_CONTROL, K2_CONTROL, X4_TEST, X8_TEST, h)
    true_sizes.append(np.abs(div_true).max())
    control_sizes.append(np.abs(div_control).max())
true_sizes, control_sizes = np.array(true_sizes), np.array(control_sizes)
```

Eleven steps $h = 0.2/2^n$, $n = 0, \ldots, 10$, from 0.2 down to about 0.0002. At the point $x_4 = 1$, $z = 0.5$ the loop computes the largest of the eight components of the divergence for the true condensate and for the control.

```
ratios = true_sizes[:6] / true_sizes[1:7]  # halving h from 0.2 to 0.003125
check(np.all((ratios > 3.6) & (ratios < 4.4)),
      "true condensate: halving h divides the divergence by about 4 (error h^2)")
check(true_sizes[8] < 1e-6 * size_true,
      "true condensate: the divergence falls below 1e-6 of the tensor's size")
check(abs(control_sizes[-1] / control_sizes[-2] - 1) < 1e-3
      and control_sizes[-1] > 1e-2 * size_true,
      "control: the divergence tends to a nonzero value (it is not conserved)")
```

Three checks. If the exact divergence of the true condensate is zero, what remains is the error of the finite differences, proportional to h^2: halving h must divide it by about 4 (`&` means "and" for arrays; the ratios of six successive halvings must lie between 3.6 and 4.4). At $h = 0.2/2^8 \approx 0.00078$ it must be below 10^{-6} of the size of the tensor. For the control the divergence must settle at a nonzero value: its last two values agree to 10^{-3} and exceed 10^{-2} of the size of the tensor.

```
for x4_point, z_point in ((2.0, 1.0), (0.5, 1.2)):
    x0_point = z_point / (6 * H9)
```

```
    coarse, size_other = divergence(M_TRUE, K2_TRUE, x4_point, x0_point, 1e-3)
    fine, _ = divergence(M_TRUE, K2_TRUE, x4_point, x0_point, 1e-4)
    shrink = np.abs(coarse).max() / np.abs(fine).max()  # about 10^2 for an h^2 error
    check(90 < shrink < 110 and np.abs(fine).max() < 1e-5 * size_other,
          f"true condensate conserved at x4 = {x4_point}, z = {z_point} "
          "(h = 0.001 and 0.0001)")
```

Two more points of the history. Dividing the step by 10 must divide an error proportional to h^2 by about 100, and the finer result must be below 10^{-5} of the size of the tensor.

```
WL = "Revision/theory/reports/wolfram-field-theory.json"
check(recorded(WL, "exact_solution_nonlinear_homogeneous_C") == "PASS"
      and recorded(WL, "conservation_on_shell_general") == "PASS",
      "the record proves the conservation that these numbers confirm",
      record=f"{WL}, checks exact_solution_nonlinear_homogeneous_C and "
             "conservation_on_shell_general")
for h, t_size, c_size in zip(steps[::2], true_sizes[::2], control_sizes[::2]):
    say(f"h = {h:.5f}:  true condensate {t_size:.2e},  control {c_size:.4f}")
```

The last check confirms that the record proves the conservation exactly. The loop prints every second step (`[::2]` takes every second entry): the true condensate's divergence falls from $5.06 \cdot 10^{-3}$ at $h = 0.2$ to $4.47 \cdot 10^{-9}$ at $h = 0.0002$, by about 16 for each factor 4 in h, while the control's settles at 0.0676. Six PASS lines in all.

In [18], the convergence (Figure 09c.4).

```
fig, ax = plt.subplots()
ax.loglog(steps, true_sizes, "o-", label="true condensate")
ax.loglog(steps, control_sizes, "s-", label="control (no $3H\\gamma^{(0)}$ term)")
ax.loglog(steps, true_sizes[0] * (steps / steps[0]) ** 2, "k:",
          label="proportional to $h^2$")
ax.set_xlabel("finite-difference step $h$")
ax.set_ylabel("largest $|\\nabla_\\mu T^\\mu{}_\\nu|$")
ax.set_title("Conservation of the full tensor of a condensate")
ax.legend()
save_figure(fig, "conservation_convergence",
            "The largest of the eight components of the covariant divergence "
            ...)
```

`ax.loglog` draws with logarithmic scales on both axes; `"o-"` draws circles joined by lines, `"s-"` squares. The dotted line is proportional to h^2. **What Figure 09c.4 shows.** The largest component of the divergence (energy per unit volume per unit length) against the step h, both axes logarithmic. The circles of the true condensate fall along the dotted h^2 line over six powers of ten, so the exact divergence is zero; the squares of the control stay near 0.07. The student should see how a convergence plot separates an error of the method (which shrinks with h) from a real failure (which does not).

In [19], the eight components (Figure 09c.5).

```
div_true, _ = divergence(M_TRUE, K2_TRUE, X4_TEST, X8_TEST, 1e-3)
div_control, _ = divergence(M_CONTROL, K2_CONTROL, X4_TEST, X8_TEST, 1e-3)
```

```
positions = np.arange(8)
fig, ax = plt.subplots()
floor = 1e-16  # zero components are drawn at this height on the logarithmic axis
ax.bar(positions - 0.2, np.abs(div_true) + floor, width=0.4, label="true condensate")
ax.bar(positions + 0.2, np.abs(div_control) + floor, width=0.4,
       label="control (no $3H\\gamma^{(0)}$ term)")
ax.set_yscale("log")
ax.set_ylim(1e-16, 10.0)
ax.set_xticks(positions, [f"$\\nu = {n[0]}_{n[1]}$" for n in NAMES], fontsize=8)
ax.set_ylabel("$|\\nabla_\\mu T^\\mu{}_\\nu|$ (with $h = 0.001$)")
ax.set_title("The eight components of the divergence")
ax.legend(fontsize=8)
save_figure(fig, "divergence_components",
            "The eight components $|\\nabla_\\mu T^\\mu{}_\\nu|$, $\\nu = x_0, \\dots, "
            "x_7$, of the divergence of the full tensor of the condensate of the "
            ...)
```

At $h = 0.001$ the cell draws the size of each of the eight components for both configurations as bars on a logarithmic axis; 10^{-16} is added so that an exact zero, which a logarithmic axis cannot show, is drawn at the bottom. **What Figure 09c.5 shows.** For $\nu = x_0, \dots, x_7$: the true condensate's bars all lie at the level of the finite-difference error, below 10^{-6}; the control's bars for the six momentum components $\nu = x_1, x_2, x_3, x_5, x_6, x_7$ stand between about 0.01 and 0.07, while its components $\nu = x_4$ and x_0 vanish. The student should see what Section 9.26 explained: the control keeps the energy and hidden balances (its ρ and pressures are those of the true condensate) but breaks the momentum balances; the gravitational term $3H\gamma^{(0)}$ is needed for the conservation of the tensor.

```
momentum = [1, 2, 3, 5, 6, 7]  # the components nu = x1, x2, x3, x5, x6, x7
check(np.abs(div_control).max() > 1e3 * np.abs(div_true).max()
      and np.abs(div_control[momentum]).min() > 1e-3
      and max(abs(div_control[4]), abs(div_control[0])) < 1e-9,
      "control: its six momentum components are nonzero (over 1000 times the true "
      "condensate's), its x4 and x0 components vanish")
```

The check confirms what the figure shows: the control's divergence is more than 1000 times the true condensate's, each of its six momentum components exceeds 10^{-3}, and its x_4 and x_0 components are below 10^{-9}.

In [20], the last check.

```
captions = json.loads(output_file(CAPTION_FILE).read_text(encoding="utf-8"))
expected_files = ["09c_1_generic_condensate.png", "09c_2_offdiagonal_entries.png",
                  "09c_3_witness_condensate.png",
                  "09c_4_conservation_convergence.png",
                  "09c_5_divergence_components.png"]
check(sorted(captions) == expected_files and all(
    output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected_files),
    "the five figures of this notebook are saved and captioned")
all_checks_passed()
```

The five figures exist and are captioned, and the last line is `ALL 25 CHECKS PASSED (notebook 09c)`: three checks in In [5], two in In [7], one each in In [8], In [9] and In [10], three in In [11], two

in In [12], two in In [13], one each in In [14] and In [15], six in In [17], and one each in In [19] and In [20].

9.31 What we proved, what we computed, what we assumed

PROVED in this chapter, line by line (and in the Revision record, with the file and check named in the section):

- For the diagonal vielbein of the author's metric, $\{\gamma^\mu, \Omega_\mu\} = 0$ for each direction and $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(0)}$; the a_4' terms cancel because the extra times deflate (Section 9.3).
- From the definition of the energy-momentum tensor by the variation of the action, the diagonal entries $T^\mu{}_\mu = L_0 - K_\mu$ (Section 9.5); the reality of every entry and the symmetry of $T_{\nu\mu}$ (Section 9.6).
- $\rho = -\sum_{\mu\neq x_4} K_\mu + mS + U$, $p_\mu = \sum_{\nu\neq\mu} K_\nu - mS - U$, with their kinetic and potential parts (Section 9.7); the trace $7\sum_\mu K_\mu - 8(mS+U)$ and the kinetic-sum identity off shell, and on shell $\sum_\mu K_\mu = (m+U')S$, $L_0 = SU' - U$ and the trace $-mS + 3\lambda S^2$ (Section 9.8).
- The 25 Christoffel symbols; the lemma $\Gamma^\mu{}_{\mu\nu} = \partial_\nu \ln f_\mu$; the divergence of a diagonal tensor; the two conservation identities $\partial_4\rho = -3a_4'(p_3 - p_t)$ and $\partial_0 p_0 = -3H\cot z\,(2p_0 - p_3 - p_t)$; the vanishing of the other six components (Section 9.9); the profiles $p_0 = P/2 + c/\sin z$ and the form in the coordinate y (Section 9.11).
- The connection term $K^{x_4}{}_{x_1} = \frac{1}{2}e^{a_4}\sin^{1/6} z\, H\,\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi$ of a homogeneous configuration (Section 9.12) and the entries $T^{x_1}{}_{x_5} = \frac{1}{2}e^{-2a_4}a_4'\,\bar\Phi\gamma^{(1)}\gamma^{(4)}\gamma^{(5)}\Phi$ and $T^{x_4}{}_{x_1} = \frac{7}{4}e^{a_4}\sin^{1/6} z\, H\,\bar\Phi\gamma^{(1)}\gamma^{(4)}\gamma^{(0)}\Phi$ of a condensate (Section 9.26), equal to the record's coefficients.
- The exact condensates, the constancy of S, $M^2 = 9H^2 - V^2$; their $\rho = mS + U$, $p = SU' - U$ in all seven directions, $T^{x_4}{}_{x_0} = 0$, and $w = x/(2+x)$ with its special values (Sections 9.18 to 9.20); $\rho = E\,u^\dagger B u$ for plane waves of flat space (Section 9.21); in the construction of the witnesses, the dimension 8 of the space of the eigenvalue $-i\omega$ and the dimension 1 of each of its eight sectors, and $S = 2|v_1^\dagger C v_2|^2 \geq 0$ (Section 9.26); the argument of the theorem of the linear history from the record's evolution equation (Section 9.26).

PROVED in the Revision record and used here without its proof: the vielbein-variation tensor with its spin-density term; the complete (Belinfante) tensor as its symmetric part for every configuration, and the equality of the two tensors on shell in all 64 entries (off shell, in general, only the 8 diagonal entries agree); the drop-out of the spin connection from the Lagrangian of every diagonal vielbein; the conservation $\nabla_\mu T^\mu{}_\nu = 0$ of every solution (Noether identity); the same formulas for the Grassmann field dirac16complex; the positive Fock realisation of the quantised field for single good-sector momenta with frozen coefficients, and the complex frequencies of the curved good sector without a boundary condition at $z = \pi/2$ (for $U = 0$ whenever $m^2 < 9H^2$); in the finite Fock model of one good-sector mode set with frozen coefficients, the operator form of the on-shell identity for $\lambda \neq 0$ when the potential and the tensor are both Wick ordered, its failure for every other ordering tested, and the exact values $\rho = mn + \frac{\lambda}{2}n(n-1)$ and $p = \frac{\lambda}{2}n(n-1)$ on the occupation states with n quanta at rest (Section 9.13); the 42 off-diagonal entries of a condensate as multiples of 15 bilinears with the listed coefficients, the diagonal witnesses with $\omega = 4, 3, 4$; the Krein inertia

(4,4) of the plane waves; the vanishing of every off-diagonal entry of the source and the condition $p_3 + p_t = 2p_0$, both imposed by the field equations of gravity; and the theorem that a condensate source that meets the off-diagonal conditions allows only the linear history $a_4 = AHx_4 + a_0$ (under its four hypotheses, Section 9.26), with either sign of A; and, in the dark-sector record, the equation of state w_{eff} that a 3-space observer infers for a homogeneous condensate: 0 under the definitions A and B of the observer's energy density and -1 under C (Section 9.19; the definitions themselves are ASSUMED).

COMPUTED by the notebooks (every number reproduces the record where they overlap): Notebook 09a, 27 checks, confirms the tensor identities at one point to 10^{-11} or better, re-derives the 25 Christoffel symbols and the two identities exactly, and checks the x_0 profiles on a grid to a relative residual of $2.3 \cdot 10^{-5}$; Notebook 09b, 33 checks, confirms the condensates at 401 times to 10^{-9}, measures w on twelve exact solutions (agreement with $x/(2+x)$ to 10^{-9}), solves the toy fluids with RK4 (relative error $1.33 \cdot 10^{-8}$, error ratio 16.17 for a halved step) and reproduces $\rho = \pm 5$; Notebook 09c, 25 checks, confirms the 42 entries against the record's coefficients to 10^{-12}, the dimensions 8 and 1 of the construction of the witnesses, the diagonal tensor of the witnesses at 36 points, the record's frequencies exactly and its values of S up to one common factor (40000 for the Wolfram report of 2026-10-08), and the conservation of the full tensor along a curved history (an error falling like h^2, down to $4.5 \cdot 10^{-9}$), with a negative control. The observation $S = 2\omega^2/V^2$ for the three witnesses is COMPUTED, not proved.

ASSUMED, chosen, or an interpretation. The sign conventions $\rho = -T^{x_4}{}_{x_4}$ and $p_\mu = T^\mu{}_\mu$ are definitions. The histories $a_4 = AHx_4$ ($A = 1$) and $a_4 = 0.3x_4 + 0.05x_4^2$ and every parameter value of the examples are choices; every identity holds for every history. The first-law reading of the x_4 identity is an interpretation, not an extra result. The toy fluids are an ILLUSTRATION, not solutions of the field equations. The normalisations A, B and C of the observer's energy density, quoted in Section 9.19 from the dark-sector record, are ASSUMPTIONS of that record.

OPEN. Which normalisation of the observer's energy density over the extra times, if any, describes a physical observer in 3-space, and a fit to supernova data (the Revision record computes the equation of state that such an observer would infer, its change in time, fits of the CPL form $w(a) = w_0 + w_a(1-a)$, a straight line in the 3-space scale factor a named after Chevallier, Polarski and Linder, and the comparison with the Unite values, all under the ASSUMED definitions A, B and C; Chapter 22, COMPUTED); the operator (normal-ordered) form of the on-shell kinetic-sum identity $\sum_\mu \langle{:}K_\mu{:}\rangle = \langle{:}(m + U')S{:}\rangle$ for $\lambda \neq 0$ for the field on a whole slice (Section 9.13; it is verified only in the finite Fock model of one good-sector mode set with frozen coefficients, and there only under Wick ordering), and with it the operator form of the on-shell values of L_0 and of the trace, and the symmetry and conservation of the quartic operator; a space of quantum states with positive norms for the full quantised field (positive Fock spaces are constructed only for single good-sector momenta with frozen coefficients); a condensate that realises the deflating history together with all the field equations of Einstein-Lovelock gravity with α_2 or α_3 different from zero, for definite values of the constants (for Einstein gravity Chapter 12 constructs such solutions, under the ASSUMED inputs it states). Any reading of the negative energies of the commuting field as a phantom dark energy is a HYPOTHESIS, not a result.

Not claimed. Nothing in this chapter concerns the creation of universes or the matter-antimatter asymmetry. The only link to Part V is the sign reversal of the tensor under the chirality map Γ (theorem T1, Section 9.21), an exact map between sets of solutions in a fixed gravitational field; it proves no creation process, rate or amplitude (Chapters 18 to 21 state what the pairing theorems

prove and what they do not).

9.32 Exercises

Exercise 1. Use the lemma $\Gamma^{\mu}{}_{\mu\nu} = \partial_\nu \ln f_\mu$ of Section 9.9 to compute $\Gamma^{x_5}{}_{x_5 x_4}$ and $\Gamma^{x_5}{}_{x_5 x_0}$, and compare with the table.

Answer. $\ln f_5 = \ln\left(e^{-a_4}\sin^{1/6} z\right) = -a_4 + \frac{1}{6}\ln\sin z$. Differentiating with respect to x_4: only $-a_4$ depends on x_4, so $\Gamma^{x_5}{}_{x_5 x_4} = -a_4'$. Differentiating with respect to x_0 with the chain rule ($dz/dx_0 = 6H$): $\Gamma^{x_5}{}_{x_5 x_0} = \frac{1}{6}\cdot\frac{\cos z}{\sin z}\cdot 6H = H\cot z$. The table lists $\Gamma^{x_t}{}_{x_4 x_t} = -a_4'$ (the symbol is symmetric in its lower indices) and $\Gamma^{x_t}{}_{x_t x_0} = H\cot z$.

Exercise 2. Suppose the extra times inflated like 3-space, with the factors $f_5 = f_6 = f_7 = e^{+a_4}\sin^{1/6} z$ (this is not the author's metric). Use the divergence formula for a diagonal tensor to find the x_4 identity, and explain the difference from Section 9.10.

Answer. Now $\partial_4 \ln f_\mu = a_4'$ for all six directions $x_1, x_2, x_3, x_5, x_6, x_7$, and 0 for x_4 and x_0. With $T^{x_4}{}_{x_4} = -\rho$: $\nabla_\mu T^{\mu}{}_{x_4} = -\partial_4\rho + 3a_4'(-\rho - p_3) + 3a_4'(-\rho - p_t) = -\partial_4\rho - 3a_4'(2\rho + p_3 + p_t)$. Conservation gives $\partial_4\rho = -3a_4'(2\rho + p_3 + p_t)$. This has the form of the familiar cosmological law $d\rho/dt = -3(\dot a/a)(\rho + p)$, once for each family of three directions: the volume $\sqrt{|g|} = e^{6a_4}\cos z$ grows, and the energy density is diluted. In the author's metric the volume is constant, the two terms $\mp 3a_4'\rho$ cancel, and only the difference $p_3 - p_t$ remains.

Exercise 3. A condensate has $m = 1$, $S = 1$ and $\lambda = 0.5$. Compute ρ, p, w and the trace in two ways. Repeat for $\lambda = -0.5$, and compare with the numbers printed by Notebook 09b.

Answer. $\lambda = 0.5$: $\rho = mS + \frac{\lambda}{2}S^2 = 1 + 0.25 = 1.25$; $p = \frac{\lambda}{2}S^2 = 0.25$; $w = 0.25/1.25 = 0.2$ (also $x/(2+x)$ with $x = 0.5$: $0.5/2.5 = 0.2$). Trace: $-\rho + 7p = -1.25 + 1.75 = 0.5$, and $-mS + 3\lambda S^2 = -1 + 1.5 = 0.5$. $\lambda = -0.5$: $\rho = 1 - 0.25 = 0.75$, $p = -0.25$, $w = -1/3$ (and $x/(2+x) = -0.5/1.5$); trace $-0.75 - 1.75 = -2.5 = -1 - 1.5$. Notebook 09b prints $\rho = 1.25$, $p = 0.25$, $w = 0.2$ and $\rho = 0.75$, $p = -0.25$, $w = -0.333333$.

Exercise 4. For $m > 0$ and $\lambda \neq 0$, find the value of S for which a condensate has $w = -1$, compute its ρ and p, and decide the sign of ρ. Does this condensate oscillate or grow?

Answer. $w = -1$ requires $x = \lambda S/m = -1$, that is $S = -m/\lambda$. Then $\rho = mS + \frac{\lambda}{2}S^2 = -\frac{m^2}{\lambda} + \frac{\lambda}{2}\cdot\frac{m^2}{\lambda^2} = -\frac{m^2}{\lambda} + \frac{m^2}{2\lambda} = -\frac{m^2}{2\lambda}$ and $p = \frac{\lambda}{2}S^2 = \frac{m^2}{2\lambda}$, so indeed $p = -\rho$. The energy density is positive only for $\lambda < 0$ (then $S = -m/\lambda > 0$); for $\lambda > 0$ it is negative. The effective mass is $V = m + \lambda S = 0$, so $k^2 = 9H^2 - 0 = 9H^2 > 0$: the condensate grows, like e^{3Hx_4}.

Exercise 5. A toy fluid (an illustration) has $w_3 - w_t = 1/3$ on the history $a_4 = AHx_4$ with $H = 0.25$. Compute $\rho(8)/\rho(0)$ for $A = 1$ and for $A = -1$, and their product.

Answer. $\rho(x_4)/\rho(0) = e^{-3AH(w_3 - w_t)x_4}$. For $A = 1$ the exponent at $x_4 = 8$ is $-3\cdot 0.25\cdot\frac{1}{3}\cdot 8 = -2$, so the ratio is $e^{-2} = 0.135335$, the number of Notebook 09b. For $A = -1$ it is $e^{2} = 7.389056$. The product is $e^{-2}e^{2} = 1$: reversing the history reverses the energy flow.

Exercise 6. Suppose $p_3 + p_t = P$ is a constant and the hidden pressure p_0 stays finite as $z \to 0$. Show that $p_0 = P/2$ everywhere.

Answer. By Section 9.11 every solution of the x_0 balance is $p_0 = P/2 + c/\sin z$ with a constant c. As $z \to 0$, $\sin z \to 0$, so $c/\sin z$ grows without bound unless $c = 0$. A finite p_0 therefore needs $c = 0$,

and then $p_0 = P/2$ at every z.

Exercise 7. Show that the kinetic term K_μ is a real number.

Answer. Let $Y = \bar{\Phi}\gamma^{(\mu)}\partial_\mu\Phi = \Phi^\dagger(C\gamma^{(\mu)})\partial_\mu\Phi$. Since $C\gamma^{(\mu)}$ is real, $Y^* = \Phi^T(C\gamma^{(\mu)})(\partial_\mu\Phi)^*$. A single number equals its transpose, so $Y^* = (\partial_\mu\Phi)^\dagger(C\gamma^{(\mu)})^T\Phi$; since $C\gamma^{(\mu)}$ is antisymmetric, $Y^* = -(\partial_\mu\Phi)^\dagger C\gamma^{(\mu)}\Phi = -\partial_\mu\bar{\Phi}\,\gamma^{(\mu)}\Phi$ (because $\partial_\mu\bar{\Phi} = (\partial_\mu\Phi)^\dagger C$). Hence $\bar{\Phi}\gamma^{(\mu)}\partial_\mu\Phi - \partial_\mu\bar{\Phi}\gamma^{(\mu)}\Phi = Y + Y^*$, which is twice the real part of Y, and $K_\mu = (Y + Y^*)/(2f_\mu)$ is real.

Exercise 8. Use the derivation of Section 9.26 to show that the entry $T^{x_1}{}_{x_5}$ of a condensate vanishes at every moment at which $a_4' = 0$, and evaluate its coefficient at $a_4 = 0.5$, $a_4' = 0.25$. Which number of Notebook 09c does it reproduce?

Answer. Section 9.26 gives $T^{x_1}{}_{x_5} = \frac{1}{2}e^{-2a_4}a_4'\,\bar{\Phi}\gamma^{(1)}\gamma^{(4)}\gamma^{(5)}\Phi$, which is zero when $a_4' = 0$ (the H terms of $K^{x_1}{}_{x_5}$ and of $g^{11}g_{55}K^{x_5}{}_{x_1}$ cancel exactly). At $a_4 = 0.5$, $a_4' = 0.25$ the coefficient is $\frac{1}{2}e^{-1}\cdot 0.25 = 0.5\cdot 0.367879\cdot 0.25 = 0.045985$. Notebook 09c prints `T^x1_x5 = -(-0.045985) x its bilinear` in In [9], and In [7] shows that $T^{x_1}{}_{x_5}$ is proportional to a_4'.

Exercise 9. For the plane wave of Section 9.21 with $m = 2$ and $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, find the positive frequency E and the energy density of a wave whose unit column satisfies $Bu = -u$. What is the energy density of the same wave multiplied by 10?

Answer. $h^2 = (m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2)\cdot 1 = (4+1+4+0+16)\cdot 1 = 25$, so $E = 5$. With $\rho = E\,u^\dagger Bu$ and $u^\dagger Bu = -u^\dagger u = -1$: $\rho = -5$. Multiplying the wave by 10 multiplies every bilinear by $10^2 = 100$: $\rho = -500$. There is no lower bound.

10 Canonical quantisation in 4+4: Krein space and the good sector

Chapters 7 to 9 treated the field dirac16complex as a classical field: 16 complex anticommuting numbers $\Psi_1, \ldots, \Psi_{16}$ at every point of the author's 4+4 dimensional universe, with a Lagrangian, a field equation and an energy-momentum tensor. This chapter makes the field a quantum field. It follows the standard recipe, canonical quantisation with the time x_4, step by step, and finds what is new in signature (4,4): the quantum rule contains the matrix B, which has eight positive and eight negative eigenvalues, so the space of quantum states cannot carry an ordinary positive inner product when the field operators are read in the ordinary way; it is a Krein space. In the good sector (waves that do not depend on the three extra times) a positive state space is constructed and checked for each single momentum with frozen coefficients (flat-frame plane waves, in which the deflation of the extra times does not enter), with particles and antiparticles of positive energy. The chapter shows exactly how far this goes, where it stops, and what the quantum theory says about the pairing of universes of masses $+m$ and $-m$.

10.1 What this chapter does

Why quantise. Dirac's equation of 1928 describes one electron as a classical wave. It has waves of negative energy, and a classical theory cannot say why an electron does not fall into them. Quantum field theory answers: the field becomes a collection of operators that create and destroy particles, the negative-energy waves describe antiparticles, and every particle and every antiparticle has positive energy. The same recipe is applied here to dirac16complex, the author's fermion field with 16

complex anticommuting components (a spinor of Pin(4,4), Chapter 5). The second field of the theory, dirac16complex00, with 16 commuting components, is a classical ("semi-classical") field in the author's definition and is not quantised; Section 10.22 shows what that means for its energy.

What happens in signature (4,4). The recipe has three steps: read off from the Lagrangian the term with the time derivative; turn it into an anticommutator of the field operators; find a space of quantum states on which operators with this anticommutator act. In ordinary 3+1 dimensional physics the anticommutator is the identity matrix and the state space is an ordinary Hilbert space. Here the anticommutator is the matrix $B = -iC\gamma^{(x_4)}$, and the chapter proves that no space with a positive inner product carries it when $\Psi^\dagger$ is read as the ordinary adjoint. That is the central fact of the chapter, and everything else is built around it:

- one-particle waves: the evolution of a plane wave conserves the Krein form $u^\dagger Bu$, its frequencies are real or imaginary according to the sign of $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$, and at every real frequency the waves of one frequency carry four directions of positive and four of negative Krein form (Sections 10.2 to 10.6, Notebook 10a);
- quantum states, fermion modes and the Fock space from zero, the canonical rule, the theorem that forces the Krein space, and the conjugation of the quantised field (Sections 10.11 to 10.15, Notebook 10b);
- the good sector and its positive Fock space (one momentum with frozen coefficients), the Dirac sea and normal ordering, the energy-momentum tensor operator, and the contrast with the classical commuting field (Sections 10.20 to 10.22, Notebook 10c);
- the curved good sector of the author's metric, where Hermiticity needs a boundary condition at the patch end $z = \pi/2$ (Sections 10.27 and 10.28, Notebook 10d);
- the proof that no invariant choice of the charge density is positive, and the symmetries that keep the canonical rule (Sections 10.33 and 10.34, Notebook 10e);
- the same structure along the deflating history of the extra times, where every wave with extra-time momentum eventually grows (Section 10.39, Notebook 10f);
- the quantum reading of the pairing of universes of masses $+m$ and $-m$, with an exact list of what it does not establish (Sections 10.44 and 10.45, Notebook 10g).

The chapter closes with "What we proved, what we computed, what we assumed" (Section 10.50), with exercises (Section 10.51) and with their complete answers (Section 10.52).

The seven worked examples. Each is a complete Jupyter notebook; each is complete in itself, so you may run them in any order.

notebook	what it computes	checks	figures
10a	one-particle spectra and Krein inertia	28	6
10b	the canonical rule on a Fock space; the Krein space	25	5

notebook	what it computes	checks	figures
10c	the positive Fock space of one good-sector momentum	14	5
10d	the curved good sector along the hidden direction	16	5
10e	invariant forms and Krein-unitary generators	15	5
10f	the Krein structure along the deflating history	19	5
10g	the quantum reading of the pairing	30	5

Notation. The author's coordinates are written $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates (scale factor $e^{a_4} \sin^{1/6} z$); x_4 is the time; x_5, x_6, x_7 are the three extra times, which are time-like and DEFLATE EXPONENTIALLY (scale factor $e^{-a_4} \sin^{1/6} z$ with a_4 increasing); x_0 is the hidden space direction, with $z = 6Hx_0$ between 0 and $\pi/2$ and $H > 0$ the author's constant. The flat frame metric is $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$. The gamma matrices are the author's eight real 16×16 matrices; the one of the direction x_a is written $\gamma^{(x_a)}$, and they obey the Clifford relation $\gamma^{(x_a)}\gamma^{(x_b)} + \gamma^{(x_b)}\gamma^{(x_a)} = 2\eta_{ab} I_{16}$ (Chapter 4), where I_{16} is the 16×16 identity matrix and η_{ab} is η_{aa} for $a = b$ and 0 otherwise. So a space-like gamma (x_0, x_1, x_2, x_3) squares to $+I_{16}$, a time-like one $(x_4, \ldots, x_7)$ to $-I_{16}$, and two different gammas anticommute. Chapter 5 built from them the charge matrix $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ (the author's sigma16), the chirality $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)} \cdots \gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$ and the matrix $B = -iC\gamma^{(x_4)}$. For a matrix M, M^T is its transpose, M^* the matrix of the complex conjugate entries and $M^\dagger = (M^T)^*$ its conjugate transpose; for a column u, $u^\dagger$ is the row of the conjugated entries. The letter m is the mass. The words used for the status of a statement are those of the whole book: PROVED (exact, with the verifying record and check), COMPUTED (a numerical result with its accuracy), ASSUMED, HYPOTHESIS and OPEN.

The records this chapter uses. Every formula and number comes from these Revision records or from the chapter's own notebooks, which reproduce the records where they overlap:

record	what it holds
`Revision/algebra/gammas.json`	the eight gammas, C and B
`Revision/algebra/reports/`	the algebra checks: `python-algebra.json`, `wolfram-algebra.json`
`Revision/theory/reports/`	the field-theory checks: `python-field-theory.json`, `wolfram-field-theory.json`, `python-scope.json`, `wolfram-scope.json`
`Revision/theory/field-theory.json`	the formulas of the field theory
`Revision/pairing/pairing-theory.json`	the pairing theorems and their data
`Revision/pairing/reports/`	the pairing checks: `python-pairing.json`, `wolfram-pairing.json`

record	what it holds
`Revision/lead_checks/reports/`	`charge-conjugation-and-u1.json` (12 checks)
`Revision/kohn_sham/results/parameters.json`	the parameters of the deflating history
`Revision/field_equations_a4/reports/ks-source-conditions.json`	the status of that history: a prescribed background
`Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`	the theory document of the record (its sections 11 and 12: quantisation, the energy-momentum tensor operator)
`Revision/docs/PAIR_CREATION_PROOFS.md`	the proof document of the pairing (its section 6: the quantum reading Q)

A report is a file in which a verifying program has recorded each check with its name, its verdict and a detail text; every check cited in this chapter has the verdict PASS. Below, a report is named by its file name only, for example "`python-field-theory.json`, check `canonical_anticommutator_B`".

10.2 The matrix B and the Krein form

The charge. Chapter 5 showed that the current of the field is $J^\mu = -i\bar\Psi\gamma^\mu\Psi$ with $\bar\Psi = \Psi^\dagger C$, and that its time component is the charge density

$$J^{(x_4)} = -i\Psi^\dagger C\gamma^{(x_4)}\Psi = \Psi^\dagger B\Psi, \qquad B = -iC\gamma^{(x_4)}.$$

The Revision record proves the **local conservation law** $\partial_\mu(\cos z\, J^\mu) = 0$ (for the author's metric with a changing b_4 the weight is $\sqrt{|g|} = b_4^{3/2}\cos z$: `python-field-theory-b4.json`, check `u1_noether_matrix_identity_b4`) (summed over the eight directions μ, as in Chapter 1) for every solution of the field equation (`charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity`), and that $J^{(x_4)}$ is the density of the total charge $Q = \int \cos z\, \Psi^\dagger B\Psi\, d^7x$, the integral over a slice $x_4 =$ const (`wolfram-field-theory.json`, check `charge_density_is_Krein_form_G`). A local law does not by itself make Q constant. Write it as $\partial_4(\cos z\, J^{(x_4)}) = -\sum_{a\neq 4}\partial_a(\cos z\, J^{(x_a)})$ and integrate over the slice: the left side gives dQ/dx_4, and each term on the right is the integral of a derivative along one direction, which by the fundamental theorem of calculus equals the difference of the values at the two ends of that direction. So Q changes by exactly the charge that flows out through the boundary of the slice, and it is constant only when this **flux** vanishes. In flat space it vanishes for fields that die away at large distances. In the author's patch the boundary includes the patch end $z = \pi/2$, and there the flux vanishes only under a boundary condition, an ASSUMED no-flux condition that the quantisation of the Revision record does not impose; without it the constancy of Q is OPEN (Revision theory document, section 11). Sections 10.27 and 10.28 show an exact solution whose charge Q grows from 1/6 to 454.007. For two columns u and v of 16 complex numbers the number $u^\dagger Bv$ is called their **Krein form**, and $u^\dagger Bu$ the **Krein norm** of u (a name, not a length: it can be negative).

Five properties of B, derived line by line. We use only the Clifford relation, the reality of the gammas, $C^T = C$, $CC = I_{16}$ and $(\gamma^{(x_4)})^T = -\gamma^{(x_4)}$ (Chapter 5).

(B1) $C\gamma^{(x_4)} = \gamma^{(x_4)}C$. Move $\gamma^{(x_4)}$ from the right of $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ to its left, one factor at a time:

$$\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}\gamma^{(x_4)} = (-1)^4\,\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}.$$

Each of the four steps exchanges $\gamma^{(x_4)}$ with a different gamma, which costs a sign by the Clifford relation; four signs give $+1$.

(B2) B is purely imaginary: $C\gamma^{(x_4)}$ is a product of real matrices, and B is $-i$ times it.

(B3) B is Hermitian, $B^\dagger = B$:

$$B^\dagger = (+i)\,(C\gamma^{(x_4)})^T = (+i)\,(\gamma^{(x_4)})^T C^T = (+i)(-\gamma^{(x_4)})C = -i\,\gamma^{(x_4)}C = -i\,C\gamma^{(x_4)} = B.$$

The first step conjugates the number $-i$ and transposes the real matrix; the second uses $(MN)^T = N^T M^T$; the third uses $(\gamma^{(x_4)})^T = -\gamma^{(x_4)}$ and $C^T = C$; the fourth collects the signs; the fifth is (B1).

(B4) $BB = I_{16}$:

$$BB = (-i)^2\,C\gamma^{(x_4)}C\gamma^{(x_4)} = -\,CC\,\gamma^{(x_4)}\gamma^{(x_4)} = -\,I_{16}\,(-I_{16}) = I_{16}.$$

The first step uses $(-i)^2 = -1$; the second moves the middle C to the left by (B1); the third uses $CC = I_{16}$ and $\gamma^{(x_4)}\gamma^{(x_4)} = \eta_{44}I_{16} = -I_{16}$.

(B5) $\operatorname{tr} B = 0$, and B has eight eigenvalues $+1$ and eight -1. The trace of a matrix is the sum of its diagonal entries; it does not change when the factors of a product are rotated, $\operatorname{tr}(XY) = \operatorname{tr}(YX)$. The chirality Γ anticommutes with every gamma (it is the product of all eight; moving one gamma through it passes seven different gammas and itself, sign $(-1)^7 = -1$), so it anticommutes with the product of the five gammas in $C\gamma^{(x_4)}$, and $\Gamma\Gamma = I_{16}$. Hence

$$\operatorname{tr} B = \operatorname{tr}(\Gamma\Gamma B) = \operatorname{tr}(\Gamma B\Gamma) = \operatorname{tr}(-B\Gamma\Gamma) = -\operatorname{tr} B,$$

so $\operatorname{tr} B = 0$. The first step inserts $\Gamma\Gamma = I_{16}$, the second rotates the first factor Γ to the end, the third moves Γ through B at the cost of a sign. If $Bu = \lambda u$ with $u \neq 0$, then $u = BBu = \lambda^2 u$, so $\lambda^2 = 1$ and $\lambda = \pm 1$; the trace is the sum of the 16 eigenvalues, and a sum of sixteen numbers ± 1 is 0 only with eight of each sign. A Hermitian matrix with p positive and n negative eigenvalues has the **signature** (p, n): B has signature (8,8).

So the Krein norm $u^\dagger Bu$ is a real number for every column (because B is Hermitian, $(u^\dagger Bu)^* = u^\dagger B^\dagger u = u^\dagger Bu$), and it is positive for the eight eigenvectors of $+1$ and negative for the eight eigenvectors of -1. Unlike the charge density $\psi^\dagger\psi$ of Dirac's electron, the charge density of dirac16complex takes both signs.

B as a table. B is i times a real signed permutation matrix: every row has exactly one nonzero entry, $+i$ or $-i$. The following table, computed from the record `Revision/algebra/gammas.json`, gives for every row r the column c of its nonzero entry and its value; so $(Bu)_r = B_{rc}\,u_c$.

row r	**column** c	**entry** B_{rc}	**row** r	**column** c	**entry** B_{rc}
1	10	$+i$	9	2	$+i$
2	9	$-i$	10	1	$-i$
3	12	$-i$	11	4	$-i$

row r	column c	entry B_{rc}	row r	column c	entry B_{rc}
4	11	$+i$	12	3	$+i$
5	14	$-i$	13	6	$-i$
6	13	$+i$	14	5	$+i$
7	16	$+i$	15	8	$+i$
8	15	$-i$	16	7	$-i$

Which gammas commute with B. B is $-i$ times the product of the five gammas of x_0, x_1, x_2, x_3, x_4. A gamma among these five passes four different gammas and itself when it is moved through the product, sign $(-1)^4 = +1$: it commutes with B. A gamma of x_5, x_6, x_7 passes five different gammas, sign $(-1)^5 = -1$: it anticommutes with B. Hence B commutes with $\gamma^{(x_1)}, \gamma^{(x_2)}, \gamma^{(x_3)}, \gamma^{(x_4)}, \gamma^{(x_0)}$ and anticommutes with $\gamma^{(x_5)}, \gamma^{(x_6)}, \gamma^{(x_7)}$, and by the same counting $\Gamma B \Gamma = -B$.

10.3 One plane wave: the mode Hamiltonian

We first study one wave of the field at a time, as a classical wave, before any quantisation. Take $U = 0$ (no self-interaction) and flat 4+4 space. Flat space is not the author's universe. The end of this section defines the **frozen-coefficient model** of the author's universe, which has the same equation with the derivatives divided by scale factors; it is an ASSUMPTION, because it also leaves out two terms of the author's field equation. The field equation in flat space is (Chapter 7)

$$\gamma^{(x_4)}\partial_4\Psi + \sum_{a\neq 4}\gamma^{(x_a)}\partial_a\Psi = m\Psi,$$

where ∂_a is the derivative with respect to x_a and the sum runs over the seven directions $a = 1,2,3,5,6,7,8$ of a slice $x_4 = \text{const}$.

Step 1. Multiply from the left by $\gamma^{(x_4)}$ and use $\gamma^{(x_4)}\gamma^{(x_4)} = -I_{16}$:

$$-\partial_4\Psi + \sum_{a\neq 4}\gamma^{(x_4)}\gamma^{(x_a)}\partial_a\Psi = m\gamma^{(x_4)}\Psi.$$

Step 2. Add $\partial_4\Psi - m\gamma^{(x_4)}\Psi$ to both sides and exchange the two sides:

$$\partial_4\Psi = -m\gamma^{(x_4)}\Psi + \sum_{a\neq 4}\gamma^{(x_4)}\gamma^{(x_a)}\partial_a\Psi.$$

Step 3. A **plane wave** is $\Psi = u(x_4)\, e^{i\sum_{a\neq 4} k_a x_a}$ with a column u that depends on the time only and real numbers k_a, the **momenta** (wave numbers) along the slice. The derivative of $e^{ik_a x_a}$ with respect to x_a is $ik_a e^{ik_a x_a}$, so each ∂_a with $a \neq 4$ becomes the factor ik_a; then the common exponential cancels:

$$\frac{du}{dx_4} = -m\gamma^{(x_4)}u + i\sum_{a\neq 4} k_a\gamma^{(x_4)}\gamma^{(x_a)}u.$$

Step 4. Multiply by i and use $i\cdot i = -1$:

$$i\frac{du}{dx_4} = h\,u, \qquad h = -im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_{a\neq 4} k_a\gamma^{(x_a)}.$$

The 16×16 matrix h is the **mode Hamiltonian** of the wave. The equation $i\,du/dx_4 = hu$ has the form of the Schrödinger equation of quantum mechanics; its solutions with $u(x_4) = u_0 e^{-iwx_4}$ are the eigenvectors $hu_0 = wu_0$, and the eigenvalue w is the **frequency** of the wave. A real w means oscillation; an imaginary $w = i\kappa$ means $e^{-iwx_4} = e^{\kappa x_4}$, growth.

Frame momenta and the deflating extra times. In the author's metric each derivative of the field equation is divided by the scale factor f_a of its direction (Chapter 6): $f_a = e^{a_4}\sin^{1/6} z$ for x_1, x_2, x_3, $f_4 = 1$, $f_a = e^{-a_4}\sin^{1/6} z$ for x_5, x_6, x_7 and $f_0 = \cot z$ (record `Revision/theory/field-theory.json`, formula `vielbein_diagonal`). A wave $e^{iq_a x_a}$ with the **coordinate momentum** q_a therefore enters the equation with the **frame momentum** $k_a = q_a/f_a$. Along 3-space $k_a = q_a e^{-a_4}\sin^{-1/6} z$ shrinks as 3-space inflates; along an extra time $k_a = q_a e^{a_4}\sin^{-1/6} z$ GROWS as the extra times deflate.

The frozen-coefficient model, and what it leaves out. The model evaluates the scale factors at one instant and one hidden position, so that the equation of that instant has constant coefficients and the plane waves above solve it with the frame momenta k_a; the extra times are never treated as static (Section 10.39 and Notebook 10f follow the frame momenta along the deflating history). But the author's field equation also contains two terms of the hidden

direction (Section 10.27; record `Revision/theory/field-theory.json`, formula `field_equation`): the derivative $\tan z\,\gamma^{(x_0)}\partial_0\Psi$, whose coefficient changes along x_0, and the spin-connection term $3H\gamma^{(x_0)}\Psi$ (Chapter 6). The model leaves both out, so it is an ASSUMPTION, an approximation whose error this chapter does not estimate. The connection term matters. Kept in the equation, it adds to h the matrix $h_c = 3iH\gamma^{(x_4)}\gamma^{(x_0)}$ (multiply $3H\gamma^{(x_0)}\Psi$ by $\gamma^{(x_4)}$ and by i, as in Steps 1 to 4). The real matrix $\gamma^{(x_4)}\gamma^{(x_0)}$ is symmetric (Chapter 5: $(\gamma^{(x_0)})^T = \gamma^{(x_0)}$ and $(\gamma^{(x_4)})^T = -\gamma^{(x_4)}$), $(\gamma^{(x_4)}\gamma^{(x_0)})^T = (\gamma^{(x_0)})^T(\gamma^{(x_4)})^T = \gamma^{(x_0)}(-\gamma^{(x_4)}) = \gamma^{(x_4)}\gamma^{(x_0)}$, so $h_c^\dagger = -h_c$; and h_c commutes with B, because $\gamma^{(x_4)}$ and $\gamma^{(x_0)}$ do (Section 10.2). Section 10.4 proves $Bh = h^\dagger B$ for the flat h; for $h + h_c$ this becomes

$$B(h+h_c) - (h+h_c)^\dagger B = (Bh - h^\dagger B) + Bh_c + h_cB = 2Bh_c = 6iH\,B\gamma^{(x_4)}\gamma^{(x_0)} \neq 0,$$

by $h_c^\dagger = -h_c$ and $h_cB = Bh_c$; the right side is not zero because B, $\gamma^{(x_4)}$ and $\gamma^{(x_0)}$ are invertible. So with the connection term the Krein form of a single wave is no longer conserved, Theorem 10.1 below does not apply, and the frequencies can be complex: Section 10.28 finds $\pm 2\sqrt{2}\,i$ for the waves that do not depend on x_0 at $m = H = 1$. Everything in Sections 10.4 to 10.6 and 10.20 holds exactly in flat 4+4 space and in the frozen-coefficient model; Sections 10.27 and 10.28 show what the terms of the hidden direction change.

10.4 The square of h, the Krein form, and three kinds of waves

The square. Write h as a sum of eight terms, $h = mE_0 + \sum_{a\neq 4} k_a E_a$, with $E_0 = -i\gamma^{(x_4)}$ and $E_a = -\gamma^{(x_4)}\gamma^{(x_a)}$. Three facts follow from the Clifford relation:

$$E_0E_0 = (-i)^2\gamma^{(x_4)}\gamma^{(x_4)} = -(-I_{16}) = I_{16},$$

$$E_aE_a = \gamma^{(x_4)}\gamma^{(x_a)}\gamma^{(x_4)}\gamma^{(x_a)} = -\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_a)}\gamma^{(x_a)} = -(-I_{16})(\eta_{aa}I_{16}) = \eta_{aa}I_{16},$$

where the second step exchanges the middle factors $\gamma^{(x_a)}\gamma^{(x_4)}$ at the cost of a sign; and any two different E's anticommute, for example

$$E_0E_a + E_aE_0 = i\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_a)} + \gamma^{(x_4)}\gamma^{(x_a)}\gamma^{(x_4)}\big) = i\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_a)} - \gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_a)}\big) = 0,$$

and in the same way $E_aE_b + E_bE_a = -\gamma^{(x_4)}\gamma^{(x_4)}(\gamma^{(x_a)}\gamma^{(x_b)} + \gamma^{(x_b)}\gamma^{(x_a)}) = 0$ for $a \neq b$. Now multiply out hh: the products of a term with itself give m^2I_{16} and $k_a^2\eta_{aa}I_{16}$, and the products of two different terms come in pairs $c_ic_j(E_iE_j + E_jE_i) = 0$. Therefore

$$h^2 = w^2 I_{16}, \qquad w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2.$$

The space-like momenta enter with $+$, the extra-time momenta with $-$ (because $\eta_{aa} = -1$ for $a = 5, 6, 7$). Every eigenvalue w' of h obeys $w'^2 = w^2$ (if $hu = w'u$ then $w^2u = hhu = w'^2u$), so the eigenvalues are $+w$ and $-w$; since $\operatorname{tr} h = 0$ (the traces of $\gamma^{(x_4)}$ and of $\gamma^{(x_4)}\gamma^{(x_a)}$ vanish, by the

argument of (B5) for a product of an odd number of gammas and by $\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_a)}) = \mathrm{tr}(\gamma^{(x_a)}\gamma^{(x_4)}) = -\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_a)})$ for two), each occurs eight times when $w \neq 0$.

Hermitian and anti-Hermitian parts. A matrix is **Hermitian** if $M^\dagger = M$ and **anti-Hermitian** if $M^\dagger = -M$. Using $(\gamma^{(x_a)})^T = \eta_{aa}\gamma^{(x_a)}$ (Chapter 5):

$$(-i\gamma^{(x_4)})^\dagger = i(\gamma^{(x_4)})^T = -i\gamma^{(x_4)},$$

$$(\gamma^{(x_4)}\gamma^{(x_a)})^\dagger = (\gamma^{(x_a)})^T(\gamma^{(x_4)})^T = -\eta_{aa}\gamma^{(x_a)}\gamma^{(x_4)} = \eta_{aa}\gamma^{(x_4)}\gamma^{(x_a)}.$$

So $-i\gamma^{(x_4)}$ and $\gamma^{(x_4)}\gamma^{(x_a)}$ for the space-like $a = 1, 2, 3, 8$ are Hermitian, while $\gamma^{(x_4)}\gamma^{(x_a)}$ for the extra times $a = 5, 6, 7$ is anti-Hermitian. Write $h = h_H + h_A$ with

$$h_H = -im\gamma^{(x_4)} - \gamma^{(x_4)}\big(k_1\gamma^{(x_1)} + k_2\gamma^{(x_2)} + k_3\gamma^{(x_3)} + k_0\gamma^{(x_0)}\big),$$

$$h_A = -\gamma^{(x_4)}\big(k_5\gamma^{(x_5)} + k_6\gamma^{(x_6)} + k_7\gamma^{(x_7)}\big).$$

h_H is Hermitian and h_A anti-Hermitian. By Section 10.2, $\gamma^{(x_4)}$ and the four space-like gammas commute with B, so h_H commutes with B; the gammas of x_5, x_6, x_7 anticommute with B while $\gamma^{(x_4)}$ commutes, so h_A anticommutes with B. Two consequences:

- h is Hermitian, and commutes with B, exactly when $k_5 = k_6 = k_7 = 0$: in the **good sector**, the waves that do not depend on the extra times;
- for all momenta, $h^\dagger B = (h_H - h_A)B = Bh_H + Bh_A = Bh$. In words, h is **Krein self-adjoint**: $Bh = h^\dagger B$.

The Krein form is conserved. Let $u(x_4)$ solve $i\,du/dx_4 = hu$, so $du/dx_4 = -ihu$ and, taking the conjugate transpose, $du^\dagger/dx_4 = iu^\dagger h^\dagger$. By the product rule

$$\frac{d}{dx_4}(u^\dagger Bu) = \frac{du^\dagger}{dx_4}Bu + u^\dagger B\frac{du}{dx_4} = iu^\dagger h^\dagger Bu - iu^\dagger Bhu = i\,u^\dagger(h^\dagger B - Bh)u = 0.$$

The last step is $h^\dagger B = Bh$. The Krein norm of every wave is constant in time, also when the wave grows; the ordinary squared length $u^\dagger u$ changes by $d(u^\dagger u)/dx_4 = iu^\dagger(h^\dagger - h)u = -2iu^\dagger h_A u$, which vanishes in the good sector only.

Three kinds of waves. Because $h^2 = w^2 I_{16}$, the exponential series of the solution collapses. The solution is $u(x_4) = e^{-ihx_4}u(0)$ with $e^X = I_{16} + X + X^2/2! + \ldots$; the even powers of $-ihx_4$ are $(-1)^j w^{2j} x_4^{2j} I_{16}$ and the odd powers are $-i(-1)^j w^{2j} x_4^{2j+1} h$, so

$$e^{-ihx_4} = \cos(wx_4)\, I_{16} - i\,\frac{\sin(wx_4)}{w}\, h,$$

by the power series of the cosine and the sine. Three cases follow:

- $w^2 > 0$: real frequencies $\pm w$, the wave oscillates;
- $w^2 = 0$ with $h \neq 0$: $h^2 = 0$ and $e^{-ihx_4} = I_{16} - ihx_4$, the wave grows linearly;
- $w^2 < 0$, that is $k_5^2 + k_6^2 + k_7^2 > m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2$: $w = i\kappa$ with $\kappa = \sqrt{-w^2}$, and since $\cos(i\kappa x_4) = \cosh(\kappa x_4)$ and $\sin(i\kappa x_4)/(i\kappa) = \sinh(\kappa x_4)/\kappa$, half of the waves grow like $e^{\kappa x_4}$.

A large enough extra-time momentum always produces growth, and the growth rate κ has no upper bound as that momentum grows: the initial-value problem with data that depend on the extra times is not well posed (Chapter 8).

10.5 Krein inertia of the eigenspaces

Projectors onto the eigenspaces. An **eigenspace** of h is the set of all columns u with $hu = w'u$ for one eigenvalue w' (with the zero column). For $w \neq 0$ define

$$P_\pm = \tfrac{1}{2}(I_{16} \pm h/w).$$

Then $P_\pm P_\pm = \tfrac{1}{4}(I_{16} \pm 2h/w + h^2/w^2) = \tfrac{1}{4}(2I_{16} \pm 2h/w) = P_\pm$, by $h^2 = w^2 I_{16}$: $P_\pm$ is a **projector** (a matrix with $PP = P$, which maps every column into one subspace, its range, and leaves the

columns of that range unchanged). And $hP_\pm = \frac{1}{2}(h \pm w^2/w\, I_{16}) = \pm w P_\pm$, so the range of P_+ is the eigenspace of $+w$ and the range of P_- that of $-w$. Since $P_+ + P_- = I_{16}$, every column is the sum of a column of each.

Krein inertia. Choose a basis $v_1, \ldots, v_d$ of a subspace and form the **Gram matrix** $G_{ij} = v_i^\dagger B v_j$. It is Hermitian; its numbers of positive, negative and zero eigenvalues do not depend on the basis chosen (a fact of linear algebra called Sylvester's law of inertia), and they form the **Krein inertia** (p, n, z) of the subspace. It says how many independent waves of the subspace carry positive, negative and zero Krein norm. A subspace on which $u^\dagger B v = 0$ for all its members has inertia $(0, 0, d)$ and is called **Krein-neutral**.

Theorem 10.1 (Krein inertia of one-particle waves). In flat 4+4 space (or in the frozen-coefficient model of Section 10.3, an ASSUMPTION that leaves out the connection term), for every real frequency, $w^2 > 0$, with or without extra-time momentum, each of the two eigenspaces of h has dimension 8 and Krein inertia (4,4). For every imaginary frequency both eigenspaces are Krein-neutral, and for $w = 0$ the range of h is Krein-neutral.

statement	status	where it is verified
Theorem 10.1, real frequencies: inertia (4,4)	PROVED	`wolfram-pairing.json`, check `Q_one_particle_Krein_inertia_real_frequencies`; `python-pairing.json`, check `Q.one_particle_Krein_inertia_proof`
Theorem 10.1, imaginary and zero frequencies: Krein-neutral	PROVED	`wolfram-pairing.json`, check `Q_one_particle_complex_and_zero_frequencies_Krein_neutral`; `python-pairing.json`, check `Q.one_particle_complex_frequency_Krein_neutral`

Proof, step (i): the two eigenspaces are Krein-orthogonal. Let $w > 0$ be real, so $P_+^\dagger = \frac{1}{2}(I_{16} + h^\dagger/w)$. Then

$$4w^2\, P_+^\dagger B P_- = (wI_{16} + h^\dagger)\, B\, (wI_{16} - h) = w^2 B - wBh + wh^\dagger B - h^\dagger B h.$$

The first step multiplies each projector by $2w$; the second multiplies out. By $h^\dagger B = Bh$ the two middle terms cancel, and $h^\dagger B h = Bhh = w^2 B$, so the right side is $w^2 B - w^2 B = 0$. A wave of frequency $+w$ and one of $-w$ have zero mixed Krein form. In the same way $P_+^\dagger B P_+ = B P_+$. Because B is invertible and the two eigenspaces together span all 16 directions, B cannot vanish on either eigenspace: if a column u of the $+w$ eigenspace had $u^\dagger B v = 0$ for all v in that eigenspace, it would also have it for all v in the other (step (i)), hence for all columns, so $Bu = 0$ and $u = BBu = 0$. Such a form is called **nondegenerate** on the eigenspace: its Gram matrix has no zero eigenvalue.

Step (ii): in the good sector the inertia is (4,4). There $Bh = hB$, so B commutes with $P_\pm$ and maps each eigenspace into itself. In the good sector h is also Hermitian (Section 10.4), so P_+

is Hermitian, and its range, the $+w$ eigenspace, has dimension $\operatorname{tr} P_+ = \frac{1}{2}(16 + \operatorname{tr} h/w) = 8$ (the trace of a projector is the dimension of its range; $\operatorname{tr} h = 0$ because h is a combination of $\gamma^{(x_4)}$ and of products of two different gammas, which have trace 0 by the argument given below for Bh). Choose an orthonormal basis $v_1, \ldots, v_8$ of this eigenspace ($v_i^\dagger v_j$ is 1 for $i = j$ and 0 otherwise); then $P_+ = \sum_i v_i v_i^\dagger$. Because Bv_j lies in the same eigenspace, $Bv_j = \sum_i v_i \, (v_i^\dagger B v_j) = \sum_i v_i G_{ij}$: the Gram matrix $G_{ij} = v_i^\dagger B v_j$ of the Krein form in this basis is exactly the matrix of B restricted to the eigenspace. So its eight eigenvalues are eigenvalues of B, each $+1$ or -1 (because $BB = I_{16}$), and the Krein inertia counts how many are $+1$ and how many -1. Their sum is the trace of the Gram matrix, $\sum_i v_i^\dagger B v_i = \operatorname{tr}(B \sum_i v_i v_i^\dagger) = \operatorname{tr}(BP_+)$, by $\operatorname{tr}(XY) = \operatorname{tr}(YX)$ for the column v_i and the row $v_i^\dagger B$. Now

$$\operatorname{tr}(BP_\pm) = \tfrac{1}{2} \operatorname{tr} B \pm \tfrac{1}{2w} \operatorname{tr}(Bh) = 0,$$

because $\operatorname{tr} B = 0$ (Section 10.2) and $Bh = mC - i \sum_a k_a C \gamma^{(x_a)}$ is a combination of C (a product of four different gammas) and of products of three or five different gammas, all of trace 0: a product of an odd number of different gammas has trace 0 by the argument of (B5), and a product of an even number k of different gammas has trace 0 because moving its first factor to the end does not change the trace but costs the sign $(-1)^{k-1} = -1$. Eight numbers ± 1 with the sum 0 are four $+1$ and four -1: inertia (4,4).

Step (iii): every real frequency. Start in the good sector and turn on the extra-time momenta slowly, keeping m, k_1, k_2, k_3, k_0 fixed. As long as $w^2 > 0$ the projectors $P_\pm$ change continuously, and by step (i) the Gram matrix of each eigenspace never has a zero eigenvalue. An eigenvalue of a continuously changing Gram matrix can change its sign only by passing through 0, which is forbidden, so the inertia stays (4,4). Every real-frequency point can be reached in this way (lowering k_5, k_6, k_7 to 0 only increases w^2).

Imaginary frequencies. Let w be an eigenvalue that is not real, and $hu = wu$, $hv = wv$. Compute $u^\dagger B h v$ in two ways: it is $w \, u^\dagger B v$; and with $Bh = h^\dagger B$ it is $u^\dagger h^\dagger B v = (hu)^\dagger B v = w^* \, u^\dagger B v$. Subtracting, $(w - w^*) \, u^\dagger B v = 0$, and $w - w^* \neq 0$, so $u^\dagger B v = 0$ on the whole eigenspace. *Zero frequency:* $h^2 = 0$ and $(hx)^\dagger B (hy) = x^\dagger h^\dagger B h y = x^\dagger B h h y = 0$. QED.

What it means. In flat 4+4 space the waves of every real frequency mix positive and negative charge half and half; the good sector removes the complex frequencies, but not this indefiniteness of the one-particle waves. The growing waves carry no charge at all: their eigenspaces are neutral.

10.6 The universes of masses $+m$ and $-m$ have the same one-particle spectrum

The pairing theorem T1 of the Revision record (proved in Chapter 18) relates the field of mass m to the field of mass $-m$ by the chirality matrix: if Ψ solves the equations with (m, λ), then $\Gamma\Psi$ solves them with $(-m, -\lambda)$. What does this do to the one-particle waves? Write $h_m(k)$ for the mode Hamiltonian of mass m and momenta k.

The chirality map. Γ anticommutes with every gamma and $\Gamma\Gamma = I_{16}$, so

$$\Gamma \gamma^{(x_4)} \Gamma = -\gamma^{(x_4)} \Gamma\Gamma = -\gamma^{(x_4)},$$

$$\Gamma\gamma^{(x_4)}\gamma^{(x_a)}\Gamma = (\Gamma\gamma^{(x_4)}\Gamma)(\Gamma\gamma^{(x_a)}\Gamma) = (-\gamma^{(x_4)})(-\gamma^{(x_a)}) = \gamma^{(x_4)}\gamma^{(x_a)},$$

where the second identity inserts $\Gamma\Gamma = I_{16}$ between the two gammas. Insert into $h_m(k)$:

$$\Gamma h_m(k)\Gamma = +im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_{a\neq 4} k_a\gamma^{(x_a)} = h_{-m}(k).$$

The mirror map. In the same way, with $\gamma^{(x_0)}\gamma^{(x_0)} = I_{16}$: $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)} = -\gamma^{(x_4)}$; $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_a)}\gamma^{(x_0)} = \gamma^{(x_4)}\gamma^{(x_a)}$ for $a \neq 4, 8$ (two sign changes); and $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_0)} = -\gamma^{(x_4)}\gamma^{(x_0)}$ (one sign change). So $\gamma^{(x_0)}h_m(k)\gamma^{(x_0)} = h_{-m}(R_0k)$, where R_0k is k with k_0 replaced by $-k_0$.

Equal spectra. If $h_mu = w'u$, then $h_{-m}(\Gamma u) = \Gamma h_m\Gamma\Gamma u = \Gamma h_m u = w'\,\Gamma u$: the matrix Γ carries every eigenvector of h_m to an eigenvector of h_{-m} with the same eigenvalue. Matrices related in this way ($N = SMS^{-1}$) are called **similar**, and similar matrices have the same eigenvalues. So the one-particle spectra of the universes of masses $+m$ and $-m$ are IDENTICAL, not opposite; the same follows from w^2, which contains the mass only as m^2. (PROVED: `wolfram-pairing.json`, checks `Q_one_particle_maps` and `Q_one_particle_Krein_signatures`; `python-pairing.json`, check `Q.one_particle_maps`.) This is statement Q4 of the quantum reading of the Revision record; Sections 10.44 and 10.45 discuss the whole quantum reading and what it does not establish.

10.7 Example: Notebook 10a computes the one-particle spectra and their Krein inertia

Notebook 10a reads the author's gammas from the record `Revision/algebra/gammas.json`, builds C and B, checks the properties of Section 10.2, builds the mode Hamiltonian of Section 10.3, proves exactly with sympy that $h^2 = w^2 I_{16}$ and $Bh = h^\dagger B$ (Section 10.4), follows the eigenvalues as the extra-time momentum grows, computes the Krein inertia of the eigenspaces for the eight samples stored in the pairing record and for a scan across the threshold of growth, repeats steps (i) and (ii) of the proof of Theorem 10.1 exactly, and checks the identities of Section 10.6. It draws six figures and ends with the line ALL 28 CHECKS PASSED (notebook 10a).

10.8 How to run Notebook 10a

Step 1. What this notebook does and what it needs.

Notebook 10a (One-particle spectra and Krein signatures) is the file `Revision/textbook/notebooks/10a_krein_spectra.ipynb` of the repository Dirac_claude. It builds the Krein matrix B from the author's gamma matrices, the one-particle mode Hamiltonian h of a plane wave in flat 4+4 space, proves exactly with sympy that h squared is the squared frequency times the identity and that B h equals h dagger B, computes the eigenvalues of h as the momentum along an extra time grows, the Krein inertia of every eigenspace (4 positive and 4 negative directions at every real frequency, none at an imaginary frequency), checks that the universes of masses +m and -m have the same one-particle spectrum, reproduces the recorded samples of the Revision pairing record, and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with

Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10a_krein_spectra.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10a_krein_spectra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 10a_krein_spectra.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10a.captions.json`
- `Revision/textbook/figures/10a_1_gamma4_c_and_b.png`
- `Revision/textbook/figures/10a_2_frequency_squared.png`
- `Revision/textbook/figures/10a_3_eigenvalue_flow.png`
- `Revision/textbook/figures/10a_4_krein_inertia_scan.png`
- `Revision/textbook/figures/10a_5_krein_gram_matrices.png`
- `Revision/textbook/figures/10a_6_plus_minus_mass_spectra.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10a_6_plus_minus_mass_spectra.png exists
ALL 28 CHECKS PASSED (notebook 10a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10a_krein_spectra.ipynb` inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10a_krein_spectra.ipynb
python -m nbconvert --execute --inplace 10a_krein_spectra.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.9 Notebook 10a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10a_krein_spectra.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when

it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook studies ONE wave of the field dirac16complex at a time: a plane wave
with fixed momenta along the seven directions of a slice $x_4 = $ const, in flat
4+4 space (or in the frozen-coefficient model of the author's universe, which has
the same equation but is an ASSUMPTION; section 4 says exactly what it leaves out).
It

- builds, from the author's gamma matrices, the matrix $B = -iC\gamma^{(x_4)}$ that
  appears in the charge density $\Psi^\dagger B \Psi$ and later in the canonical
  anticommutator, and checks that $B$ is Hermitian, squares to 1 and has eight
  eigenvalues $+1$ and eight eigenvalues $-1$;
- writes the field equation of one plane wave as $i\,du/dx_4 = h\,u$ with a
  $16 \times 16$ matrix $h$, the *mode Hamiltonian*;
- proves with exact algebra (sympy) that $h^2 = w^2 I_{16}$ with
  $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$, and that
  $B h = h^\dagger B$;
- follows the eigenvalues of $h$ as the momentum $k_5$ along the extra time $x_5$
  grows: they are real (oscillation) while $w^2 > 0$ and imaginary (growth) when
  $w^2 < 0$;
- computes the *Krein inertia* of every eigenspace: how many directions of positive
  and of negative charge it contains. The answer is 4 and 4 at every real
  frequency, and 0 and 0 (a *neutral* eigenspace) at every imaginary frequency;
- checks that the masses $+m$ and $-m$ give the SAME one-particle spectrum;
- reproduces every recorded number of the Revision record that it touches, and
  draws six teaching figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 10a (One-particle spectra and Krein signatures) is the file
‘Revision/textbook/notebooks/10a_krein_spectra.ipynb‘ of the repository Dirac_claude. It
builds the Krein matrix B from the author's gamma matrices, the one-particle mode
Hamiltonian h of a plane wave in flat 4+4 space, proves exactly with sympy that h squared
is the squared frequency times the identity and that B h equals h dagger B, computes the
eigenvalues of h as the momentum along an extra time grows, the Krein inertia of every
eigenspace (4 positive and 4 negative directions at every real frequency, none at an
imaginary frequency), checks that the universes of masses +m and -m have the same
one-particle spectrum, reproduces the recorded samples of the Revision pairing record,
and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
```

shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then

needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 10a_krein_spectra.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 10a_krein_spectra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10a_krein_spectra.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10a.captions.json‘

- ‘Revision/textbook/figures/10a_1_gamma4_c_and_b.png‘
- ‘Revision/textbook/figures/10a_2_frequency_squared.png‘
- ‘Revision/textbook/figures/10a_3_eigenvalue_flow.png‘
- ‘Revision/textbook/figures/10a_4_krein_inertia_scan.png‘
- ‘Revision/textbook/figures/10a_5_krein_gram_matrices.png‘
- ‘Revision/textbook/figures/10a_6_plus_minus_mass_spectra.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10a_6_plus_minus_mass_spectra.png exists
ALL 28 CHECKS PASSED (notebook 10a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10a_krein_spectra.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
      python -m jupyterlab 10a_krein_spectra.ipynb
      python -m nbconvert --execute --inplace 10a_krein_spectra.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
  the Revision record: the data it starts from and the report files whose checks it
  reproduces (each cited check must still exist there with the verdict PASS). It must be
  opened inside the folder Revision/textbook/notebooks of a complete copy of the
  repository (a notebook copied alone to another folder cannot find them). Clone the
  repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the
  Revision record no longer holds the check that the notebook names, or holds it with
  another verdict: the copy of the repository is incomplete or was changed. Clone the
  repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 10a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10a (One-particle spectra and Krein signatures) is the file
# Revision/textbook/notebooks/10a_krein_spectra.ipynb of the repository Dirac_claude. It
# builds the Krein matrix B from the author's gamma matrices, the one-particle mode
# Hamiltonian h of a plane wave in flat 4+4 space, proves exactly with sympy that h
# squared is the squared frequency times the identity and that B h equals h dagger B,
# computes the eigenvalues of h as the momentum along an extra time grows, the Krein
# inertia of every eigenspace (4 positive and 4 negative directions at every real
# frequency, none at an imaginary frequency), checks that the universes of masses +m and
# -m have the same one-particle spectrum, reproduces the recorded samples of the Revision
# pairing record, and draws six teaching figures. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
```

```
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
```

```
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
```

```
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10a_krein_spectra.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10a_krein_spectra.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10a_krein_spectra.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10a.captions.json
# - Revision/textbook/figures/10a_1_gamma4_c_and_b.png
# - Revision/textbook/figures/10a_2_frequency_squared.png
# - Revision/textbook/figures/10a_3_eigenvalue_flow.png
# - Revision/textbook/figures/10a_4_krein_inertia_scan.png
# - Revision/textbook/figures/10a_5_krein_gram_matrices.png
# - Revision/textbook/figures/10a_6_plus_minus_mass_spectra.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
```

```
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10a_6_plus_minus_mass_spectra.png exists
#     ALL 28 CHECKS PASSED (notebook 10a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10a_krein_spectra.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10a_krein_spectra.ipynb
#     python -m nbconvert --execute --inplace 10a_krein_spectra.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
```

```
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
#

## 3. The words used in this notebook

- **Matrix, entry, identity**: a matrix is a table of numbers; $M_{AB}$ is the entry
  in row $A$ and column $B$. $I_{16}$ (in code `np.eye(16)`) is the $16 \times 16$
  identity matrix: 1 on the diagonal, 0 elsewhere.
- **Complex conjugate, transpose, dagger**: $z^*$ changes $i$ into $-i$; $M^T$
  exchanges rows and columns; $M^\dagger = (M^T)^*$ is the *conjugate transpose*
  (in code `M.conj().T`). For a column $u$, $u^\dagger$ is the row of the
  conjugated entries, and $u^\dagger v = \sum_A u_A^* v_A$.
- **Hermitian**: $M^\dagger = M$. A Hermitian matrix has real eigenvalues.
- **Eigenvalue, eigenvector, eigenspace**: if $M u = \lambda u$ with $u \neq 0$,
  then $\lambda$ is an eigenvalue and $u$ an eigenvector; all eigenvectors of one
  eigenvalue (with the zero column) form its eigenspace.
- **Projector**: a matrix $P$ with $P^2 = P$. It maps every column into one
  subspace (its *range*) and leaves the columns of that subspace unchanged.
- **Trace**: $\mathrm{tr}\,M$, the sum of the diagonal entries; it equals the sum
  of the eigenvalues.
- **Krein form**: the number $u^\dagger B v$ for two columns $u, v$. Because $B$ is
  Hermitian, $u^\dagger B u$ is real, but it can be positive, negative or zero. In
  the theory it is the charge of the wave $u$.
- **Signature, inertia**: a Hermitian matrix with $p$ positive, $n$ negative and $z$
  zero eigenvalues has inertia $(p, n, z)$; the signature of $B$ is $(8, 8)$. The
  *Krein inertia of a subspace* is the inertia of the Krein form restricted to it.
- **Neutral subspace**: a subspace on which $u^\dagger B v = 0$ for all $u, v$ in it.
- **Plane wave, momentum, frequency**: $\Psi = u\,e^{i(k\cdot x - w x_4)}$ with a
  constant column $u$; the numbers $k_a$ are the momenta (wave numbers) along the
  slice directions and $w$ is the frequency. A real $w$ means oscillation, an
  imaginary $w = i\kappa$ means growth like $e^{\kappa x_4}$.
```

```
- **Good sector**: waves that do not depend on the extra times $x_5, x_6, x_7$,
  that is $k_5 = k_6 = k_7 = 0$.
- **Chirality** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$: the
  product of all eight gammas in the author's order.
- **sympy, numpy**: sympy computes EXACTLY with symbols (a proof for all values);
  numpy computes with floating-point numbers (about 16 digits), so its checks
  allow a tiny tolerance such as $10^{-10}$.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's coordinates are $x_1, x_2, x_3$ (ordinary 3-space), $x_4$ (the time),
$x_5, x_6, x_7$ (the three EXTRA TIMES, which deflate exponentially in the author's
metric) and $x_0$ (the hidden space direction). The frame metric is
$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \dots, x_7$:
the gammas obey $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} =
2\eta^{ab} I_{16}$, so $(\gamma^{(a)})^2 = +1$ for $x_0, x_1, x_2, x_3$ and $-1$
for $x_4, \dots, x_7$.

**From the field equation to the mode Hamiltonian, line by line.** With $U = 0$ and
without gravity (flat 4+4 space, or the frozen-coefficient model described below)
the field equation of dirac16complex is

$$\gamma^{(x_4)}\partial_4\Psi + \sum_{a \neq 4}\gamma^{(x_a)}\partial_a\Psi = m\Psi .$$

Multiply from the left by $\gamma^{(x_4)}$ and use $(\gamma^{(x_4)})^2 = -1$:

$$-\partial_4\Psi + \sum_{a \neq 4}\gamma^{(x_4)}\gamma^{(x_a)}\partial_a\Psi =
m\gamma^{(x_4)}\Psi .$$

Move $\partial_4\Psi$ to the right-hand side and everything else to the left, then
exchange the two sides:

$$\partial_4\Psi = -m\gamma^{(x_4)}\Psi + \sum_{a \neq 4}
\gamma^{(x_4)}\gamma^{(x_a)}\partial_a\Psi .$$

For a plane wave $\Psi = u(x_4)\,e^{i\sum_{a \neq 4} k_a x_a}$ every $\partial_a$
with $a \neq 4$ becomes the factor $i k_a$ (the derivative of $e^{ik_a x_a}$ is
$ik_a e^{ik_a x_a}$); cancel the common exponential:

$$\frac{du}{dx_4} = -m\gamma^{(x_4)}u + i\sum_{a \neq 4} k_a
\gamma^{(x_4)}\gamma^{(x_a)}u .$$

Multiply by $i$ (and use $i \cdot i = -1$):

$$i\frac{du}{dx_4} = h\,u,\qquad h = -im\gamma^{(x_4)} - \gamma^{(x_4)}
\sum_{a \neq 4} k_a\gamma^{(x_a)} .$$

**Frame momenta and the deflating extra times.** The numbers $k_a$ are momenta in
the local frame. In the author's metric the field equation contains the derivative
along $x_a$ divided by the scale factor $f_a$ of that direction (Revision theory
record): $f_a = e^{a_4}\sin^{1/6}z$ for $x_1, x_2, x_3$ and $f_a =
```

e^{-a_4}\sin^{1/6}z$ for the extra times x_5, x_6, x_7. A wave $e^{iq_ax_a}$ with the coordinate momentum q_a therefore has the frame momentum $k_a = q_a/f_a$: along 3-space $k_a = q_ae^{-a_4}\sin^{-1/6}z$ shrinks as 3-space inflates, and along an extra time $k_a = q_ae^{a_4}\sin^{-1/6}z$ GROWS as the extra times deflate (a_4 increasing). The *frozen-coefficient model* evaluates these factors at one time x_4 and one hidden position, so that the wave equation of that instant has constant coefficients, AND it leaves out the two terms of the hidden direction that the author's field equation also contains: the derivative $\tan z\, \gamma^{(x_0)}\partial_0\Psi$ with its coefficient that changes along x_0, and the spin-connection term $3H\gamma^{(x_0)}\Psi$ (Revision theory record, formula 'field_equation'). The model is therefore an ASSUMPTION. Kept in the equation, the connection term would add $3iH\gamma^{(x_4)}\gamma^{(x_0)}$ to the matrix h above; that matrix commutes with B and is anti-Hermitian, so it would spoil the identity $Bh = h^\dagger B$ that this notebook proves, and the frequencies could become complex. The extra times are not static: the notebook "The Krein structure along the deflating history" of this chapter follows the frame momenta, and everything this notebook computes, along the deflating history.

The Krein form is conserved. The charge density of the field is $\Psi^\dagger B\Psi$ with $B = -iC\gamma^{(x_4)}$, $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ (the author's sigma16). From $i\,du/dx_4 = hu$ we get $du/dx_4 = -ihu$ and, taking the dagger, $du^\dagger/dx_4 = i\,u^\dagger h^\dagger$. By the product rule

$$\frac{d}{dx_4}(u^\dagger B\,u) = i\,u^\dagger h^\dagger B\,u - i\,u^\dagger B h\,u = i\,u^\dagger(h^\dagger B - B h)u\ ,$$

which is zero for every u exactly when $B\,h = h^\dagger B$. The notebook proves this identity. The ordinary squared length $u^\dagger u$, on the other hand, is conserved only when h is Hermitian.

Krein inertia. Because $h^2 = w^2\,I_{16}$, for $w \neq 0$ the two matrices $P_\pm = \frac12(I_{16} \pm h/w)$ are projectors onto the eigenspaces of $\pm w$ (check: $P_\pm^2 = \frac14(I \pm 2h/w + h^2/w^2) = \frac14(2I \pm 2h/w) = P_\pm$, and $hP_\pm = \frac12(h \pm w^2/w) = \pm w\,P_\pm$). The Krein inertia of an eigenspace tells how many of its independent waves carry positive and how many negative charge. Every statement here is a statement about one-particle waves; the quantum field built from them is the subject of the later notebooks of this chapter.

Text cell:

5. The gamma matrices and the Krein matrix B

The next cell reads the author's gamma matrices from the Revision record 'Revision/algebra/gammas.json' (16 x 16 matrices of whole numbers), stores them as 'gamma[1]', ..., 'gamma[0]' so that 'gamma[a]' is $\gamma^{(x_a)}$, and checks the 64 Clifford relations exactly (whole numbers, no rounding).

It also defines 'check_record(condition, name, record)'. It does what 'check(condition, name, record=record)' of the set-up cell does (stop with an error if the condition is false, otherwise print the PASS line and the line naming the Revision record that the check reproduces), but it first collects the two printed lines and then prints them in one piece. Jupyter sends printed text to the screen

in pieces whose boundaries depend on timing; printing the two lines in one piece
keeps them together in every run, so that the stored output of the notebook is the
same every time. Before it checks anything, ‘check_record‘ asks the helper
‘record_says_pass(record)‘ whether the cited record still says what the notebook
claims: a record name of the form ‘<report file>, check <check name>‘ names a check
of a Revision report, and the helper opens that report (each file only once, kept
in the dictionary ‘REPORT_CHECKS‘) and answers True only if a check of that name
exists there with the verdict PASS. If not, the notebook stops with an error
instead of printing an outdated claim. A record name without ‘, check ‘ names a data
entry of a file that the notebook reads and compares itself.

```

Text cell:

```
The next cell builds $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$
and $B = -iC\gamma^{(x_4)}$ (in Python the imaginary unit is written `1j`), and
compares $B$ with the matrix `B` stored in the same record (its real and imaginary
parts are stored separately). Then it checks the four properties of $B$ that the
chapter uses: $B$ is purely imaginary, $B^\dagger = B$, $B^2 = I_{16}$, and its
trace is 0. Since $B^2 = I$, every eigenvalue $\lambda$ obeys $\lambda^2 = 1$, so it is
$+1$ or $-1$; the trace 0 (the sum of the eigenvalues) then forces eight of each:
the signature $(8, 8)$. The cell confirms this by computing the eigenvalues.
```

In [3]:

```
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16

Text cell:

```
The next cell defines the colours of all figures of this notebook (a blue, an
orange and a green that stay distinguishable for colour-blind readers, and a
blue-grey-red colour scale for matrices: blue for $-1$, light grey for 0, red for
$+1$) and a small function that draws a matrix as a coloured square grid, a *heat
map*. It checks what the picture will show: $\gamma^{(x_4)}$ is antisymmetric
($M^T = -M$), $C$ is symmetric ($M^T = M$), the imaginary part of $B$ is
antisymmetric, and each of the three has exactly one nonzero entry in every row
and every column. Why the imaginary part of $B$ must be antisymmetric: write
$B = iY$ with a real matrix $Y$; then $B^\dagger = (iY)^{*T} = -iY^T$, and
$B^\dagger = B$ means $-iY^T = iY$, that is $Y^T = -Y$. Then it draws
$\gamma^{(x_4)}$, $C$ and the imaginary part of $B$ side by side.
```

## 6. The mode Hamiltonian and its square

The next cell defines two functions. ‘mode_hamiltonian(m, k)‘ returns the numpy
matrix $h = -im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_a k_a\gamma^{(x_a)}$, where ‘k‘ is a
dictionary that gives the momentum $k_a$ for some of the slice directions
$a = 1, 2, 3, 5, 6, 7, 8$ (missing directions have momentum 0).
‘frequency_squared(m, k)‘ returns $w^2 = m^2 + \sum_a \eta_{aa}k_a^2$: the
space-like momenta enter with $+$, the extra-time momenta with $-$.
```

In [5]:

```
def mode_hamiltonian(m, k):
    """h = -i m gamma^(x4) - gamma^(x4) sum_a k_a gamma^(x_a), a numpy matrix;
    k is a dictionary {a: k_a} for some of the directions a = 1, 2, 3, 5, 6, 7, 8."""
    h = -1j * m * gamma[4]
    for a, k_a in k.items():
        h = h - k_a * (gamma[4] @ gamma[a])
    return h

def frequency_squared(m, k):
    """w^2 = m^2 + k0^2 + k1^2 + k2^2 + k3^2 - k5^2 - k6^2 - k7^2."""
    return m ** 2 + sum(eta[a] * k_a ** 2 for a, k_a in k.items())

example = {0: 1.3, 1: 0.3, 2: -1.1, 3: 0.7, 5: 0.4, 6: 0.2, 7: -0.9}  # any numbers

PASS numerical example: h^2 = w^2 I at one generic point
```

Text cell:

```
A numerical example is not a proof. The next cell repeats the computation EXACTLY
with sympy, for symbols $m, k_1, k_2, k_3, k_5, k_6, k_7, k_0$ that stand for any
real numbers. It checks two identities for all values at once:

- $h^2 = w^2 I_{16}$ (so every eigenvalue of $h$ is $+w$ or $-w$);
- $B h = h^\dagger B$ (so the Krein form $u^\dagger B u$ of every wave is conserved,
  as Section 4 showed).

Why $h^2 = w^2 I$ holds: $(-im\gamma^{(x_4)})^2 = -m^2(\gamma^{(x_4)})^2 = m^2$;
$(\gamma^{(x_4)}\gamma^{(x_a)})^2 = -(\gamma^{(x_4)})^2(\gamma^{(x_a)})^2 = \eta_{aa}$
```

```
for $a \neq 4$ (move the second $\gamma^{(x_4)}$ to the left past $\gamma^{(x_a)}$,
which costs a sign); and all mixed terms cancel in pairs because the matrices
$\gamma^{(x_4)}$ and $\gamma^{(x_4)}\gamma^{(x_a)}$ anticommute with each other.

## 7. The three cases: real, zero and imaginary frequency

Since $h^2 = w^2 I_{16}$, everything depends on the sign of
$w^2 = m^2 + k_s^2 - k_t^2$, where $k_s^2 = k_0^2 + k_1^2 + k_2^2 + k_3^2$ collects the
space-like momenta and $k_t^2 = k_5^2 + k_6^2 + k_7^2$ the extra-time momenta:

- $w^2 > 0$: the frequencies $\pm w$ are real and the wave oscillates;
- $w^2 = 0$: $h^2 = 0$ and the wave grows linearly in $x_4$;
- $w^2 < 0$: the frequencies are $\pm i\kappa$ with $\kappa = \sqrt{-w^2}$, and one
  half of the waves grows like $e^{\kappa x_4}$.

The next cell draws $w^2$ against $k_5$ (the only extra-time momentum here) for
$m = 1$ and three values of $k_s$, and checks that the zero crossing lies at
$k_5 = \sqrt{m^2 + k_s^2}$.
```

## 8. The eigenvalues as the extra-time momentum grows

The next cell computes the 16 eigenvalues of $h$ numerically (numpy's
`np.linalg.eigvals`) for $m = 1$, no space-like momentum, and $k_5$ from 0 to 3, and
plots their real and imaginary parts. The formula predicts eight eigenvalues
$+\sqrt{1 - k_5^2}$ and eight $-\sqrt{1 - k_5^2}$ for $k_5 < 1$, and eight $+i\kappa$
and eight $-i\kappa$ with $\kappa = \sqrt{k_5^2 - 1}$ for $k_5 > 1$. At $k_5 = 1$
exactly the matrix cannot be diagonalised and the numerical eigenvalues are only
accurate to about $10^{-8}$, so the check leaves out the points with
$|w^2| < 0.05$.
```

In [9]:

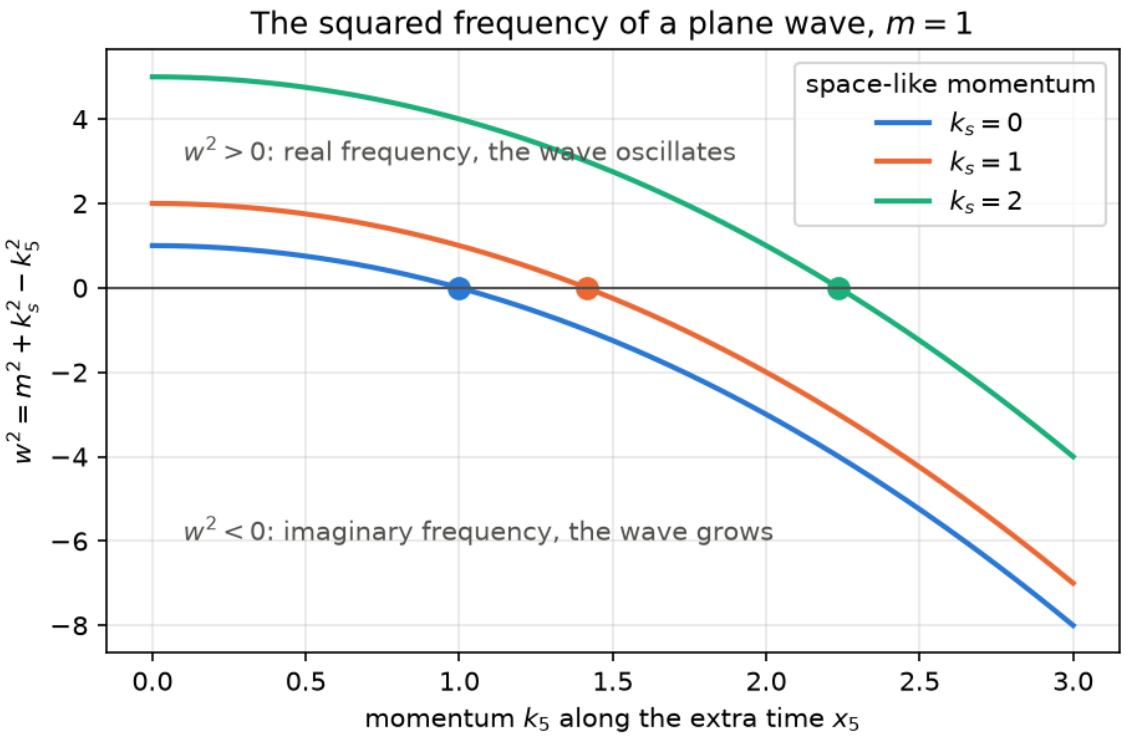

Figure 268: The squared frequency $w^2 = m^2 + k_s^2 - k_5^2$ of a plane wave with mass $m = 1$, plotted against the momentum k_5 along the extra time x_5 (horizontal axis, units of m) for the space-like momentum $k_s = 0$, 1 and 2 (the three curves). Vertical axis: w^2 in units of m^2. Above the grey line the frequency is real and the wave oscillates; below it the frequency is imaginary and the wave grows. The dots mark $k_5 = \sqrt{m^2 + k_s^2}$, where the wave changes from oscillation to growth: a large enough extra-time momentum always wins. (Notebook 10a, figure 2.)

## 9. Krein inertia of the eigenspaces: the recorded samples

The next cell defines three functions.

- ‘orthonormal_basis(P)‘ returns an orthonormal basis of the range of a matrix $P$
```

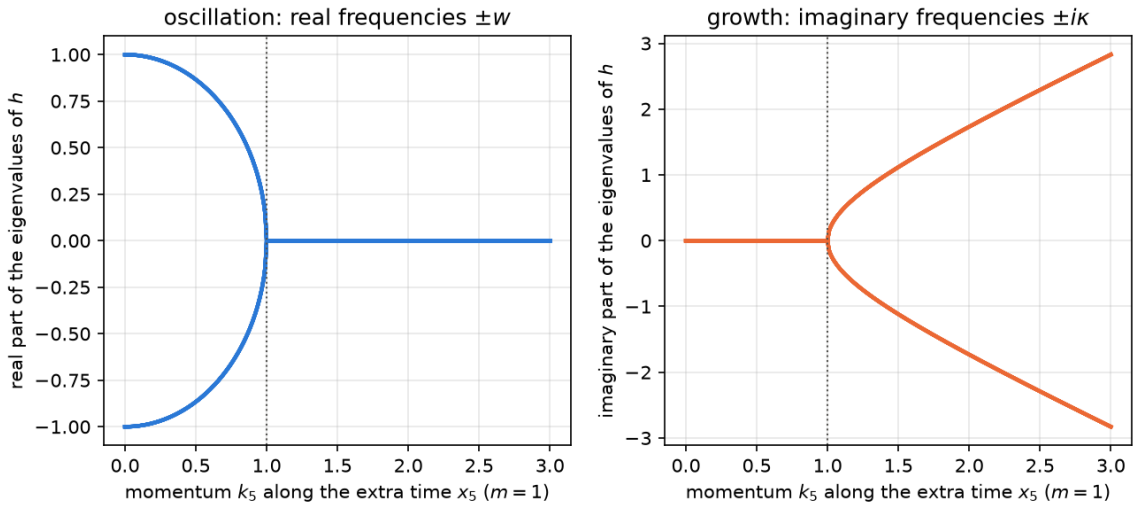

Figure 269: The 16 eigenvalues of the mode Hamiltonian h for mass $m = 1$ and only the extra-time momentum k_5 (horizontal axis, units of m): their real parts (left, blue) and imaginary parts (right, orange), vertical axes in units of m; each curve carries eight eigenvalues. For $k_5 < 1$ the eigenvalues are the real numbers $\pm\sqrt{1 - k_5^2}$, which move together and meet at 0 at $k_5 = 1$ (dotted line); for $k_5 > 1$ they leave the real axis as $\pm i\sqrt{k_5^2 - 1}$, and the waves with $+i\kappa$ grow like $e^{\kappa x_4}$. (Notebook 10a, figure 3.)

```
  by the Gram-Schmidt method: take the columns of $P$ in order, remove from each
  its parts along the basis vectors found so far, and keep it (divided by its
  length) if something is left. The procedure is repeated once to remove rounding
  errors.
- ‘eigenspace(m, k, sign)‘ returns such a basis of the eigenspace of $+w$
  (‘sign = +1‘) or $-w$ (‘sign = -1‘), as the range of the projector
  $P_\pm = \frac12(I \pm h/w)$ of Section 4. For $w^2 < 0$ the number $w$ is
  $i\kappa$, and the same formula gives the eigenspaces of $\pm i\kappa$.
- ‘krein_inertia(V)‘ computes the Gram matrix $G = V^\dagger B V$ (entry $(i, j)$ is
  the Krein form of the basis vectors $i$ and $j$) and counts its positive,
  negative and zero eigenvalues (zero means smaller than $10^{-8}$). It also returns
  the smallest size of a nonzero eigenvalue, to show that no eigenvalue is close
  to the borderline $10^{-8}$.
```

## 10. Why the inertia is (4, 4) at EVERY real frequency

Samples are not a proof. The Revision record proves the statement for every real
frequency in three steps, which the next cells repeat.

**Step (i).** For real $w > 0$: $P_+^\dagger B P_- = 0$ and $P_+^\dagger B P_+ =
BP_+$. Line by line, with $P_\pm = \frac12(I \pm h/w)$ and $P_+^\dagger = \frac12(I +
h^\dagger/w)$ ($w$ is real):

$$4w^2\,P_+^\dagger B P_- = (wI + h^\dagger)B(wI - h) = w^2 B - wBh + wh^\dagger B -
h^\dagger B h .$$

Use $h^\dagger B = Bh$ twice: the two middle terms cancel, and $h^\dagger B h = B h h
= w^2 B$, so the right-hand side is $w^2B - w^2B = 0$. Hence the two eigenspaces
are Krein-orthogonal: a wave of frequency $+w$ and one of $-w$ have zero mixed
Krein form. Since $B$ is invertible and the two eigenspaces together span all 16
directions, $B$ cannot vanish on either of them (it is *nondegenerate* on each).

**Step (ii).** In the good sector $Bh = hB$, so $\mathrm{tr}(BP_\pm) = \frac12
\mathrm{tr}B \pm \frac{1}{2w}\mathrm{tr}(Bh)$, and both traces are 0. The trace of
$BP_+$ is the sum of the eigenvalues of $B$ on the $+w$ eigenspace (in the good
sector $B$ maps this eigenspace into itself), each $+1$ or $-1$; a sum of eight
```

```
such numbers is 0 only with four of each: inertia $(4, 4)$.

**Step (iii).** Turning on the extra-time momenta slowly at fixed $m, k_1, k_2, k_3,
k_0$ keeps $w^2$ positive as long as $k_t^2 < m^2 + k_s^2$, the projectors change
continuously, and the Krein form stays nondegenerate on their ranges by step (i).
An eigenvalue of the Gram matrix could change sign only by passing through 0, which
nondegeneracy forbids: the inertia stays $(4, 4)$ at every real frequency.

The next cell checks the identities of steps (i) and (ii) exactly with sympy. The
letter $w$ is a positive symbol, and after expanding, every $w^2$ is replaced by
$m^2 + k_s^2 - k_t^2$.
```

In [13]:

```
w = sp.Symbol("w", positive=True)

Step (iii) is a statement about continuity. The next cell shows it at work: for
$m = 1$, the space-like momentum $k_1 = 0.5$ and the extra-time momentum $k_5$ from 0
to 2.5 it computes the Krein inertia of the $+w$ eigenspace. The threshold is
$k_5 = \sqrt{1.25} \approx 1.118$; points closer than 0.02 to it are skipped (there
the eigenspaces merge). Below the threshold the inertia must be $(4, 4, 0)$ at every
point, above it $(0, 0, 8)$. The cell also records the smallest size of a nonzero
```

eigenvalue of the Gram matrix: it shrinks towards the threshold but never reaches 0
before it.

In [14]:

```
threshold = np.sqrt(1.25)
scan = [k5 for k5 in np.linspace(0.0, 2.5, 251) if abs(k5 - threshold) > 0.02]

## 11. Three pictures of the Krein form on the eigenvectors

The next cell puts the 8 basis vectors of the $+w$ eigenspace and the 8 of the $-w$
eigenspace side by side as the 16 columns of a matrix $W$, and draws the sizes of the
entries of the Gram matrix $W^\dagger B W$ for three waves:

- the good-sector sample $m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$ along $(x_0,
x_1, x_2, x_3)$,
```

```
  $w = 5$;
- $m = 2$ with the extra-time momentum $k_5 = 1$: still a real frequency,
  $w = \sqrt3$;
- $m = 1$, $k_5 = 2$: an imaginary frequency, $w = i\sqrt3$.

In the first two pictures only the two diagonal $8 \times 8$ blocks are nonzero
(the eigenspaces are Krein-orthogonal, step (i)); in the third the diagonal blocks
vanish (each eigenspace is neutral) and only the off-diagonal blocks remain: a
growing wave has nonzero Krein form only with a decaying one.
```

In [15]:

```
cases = [(2, {0: 4, 1: 1, 2: 2}, "$m = 2$, $k = (4, 1, 2, 0)$: $w = 5$"),

## 12. The universes of masses $+m$ and $-m$

The pairing theorem T1 of the Revision record relates the field of mass $m$ to the
field of mass $-m$ through the chirality matrix $\Gamma$. At the one-particle level
the record proves (statement Q4 of the quantum reading):

- $\Gamma h_m(k)\Gamma = h_{-m}(k)$, because $\Gamma$ anticommutes with
  $\gamma^{(x_4)}$ and commutes with every product $\gamma^{(x_4)}\gamma^{(x_a)}$;
- $\gamma^{(x_0)} h_m(k)\gamma^{(x_0)} = h_{-m}(R_0 k)$, where $R_0$ reverses the
  hidden momentum $k_0$.

Since $\Gamma^2 = I$ and $(\gamma^{(x_0)})^2 = I$, these are *similarity*
transformations: $h_{-m}$ has exactly the eigenvalues of $h_m$. The one-particle
spectra of the two universes are IDENTICAL, not opposite. The next cell checks both
identities exactly.
```

In [16]:

```
Gamma_exact = g[0] * g[1] * g[2] * g[3] * g[4] * g[5] * g[6] * g[7]

```

Text cell:

```
The Revision theory record also states how the good-sector spectrum splits between
the two eigenspaces of $B$. In the good sector $B$ commutes with $h$, so the
projector $P_B = \frac12(I + B)$ onto the eigenvalue $+1$ of $B$ (8 directions)
commutes with $h$, and $h$ acts inside that 8-dimensional space. For the exact
example $m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $w = 5$, the matrix $P_B h P_B$
must have the
eigenvalue $+5$ four times, $-5$ four times and $0$ eight times (the 0 belongs to the
other 8 directions, which $P_B$ removes). The next cell checks this and then draws
the spectra of $h_m$ and $h_{-m}$ for $m = 2$ against $k_1$ and, at fixed $k_1 = 1$,
against $m$ from $-3$ to $3$.
```

## 14. What this notebook showed

- PROVED (exactly, with sympy, for all real $m$ and momenta): the mode Hamiltonian
  of a plane wave obeys $h^2 = w^2 I_{16}$ with $w^2 = m^2 + k_1^2 + k_2^2 + k_3^2 +
  k_0^2 - k_5^2 - k_6^2 - k_7^2$, and $Bh = h^\dagger B$, so the Krein form
  $u^\dagger B u$ (the charge) of every wave is conserved, also of a growing one;
```

```
  $h$ is Hermitian and commutes with $B$ exactly in the good sector.
- PROVED (steps (i) and (ii) exactly, step (iii) by continuity; flat 4+4 space or
  in the frozen-coefficient model, an ASSUMPTION): every eigenspace of a REAL
  frequency has Krein inertia
  $(4, 4)$; every eigenspace of an imaginary
  frequency, and the range of $h$ at zero frequency, is Krein-neutral. So the
  positive and negative charges are mixed half and half at every real frequency;
  the good sector does not remove this indefiniteness of the one-particle waves.
- PROVED (exactly): $\Gamma h_m\Gamma = h_{-m}$ and $\gamma^{(x_0)}h_m(k)\gamma^{(x_0)}
  = h_{-m}(R_8k)$: the universes of masses $+m$ and $-m$ have identical
  one-particle spectra.
- REPRODUCED: the properties of $B$ (signature $(8, 8)$), the eight recorded
  samples of the pairing record, the recorded Krein inertia and neutrality samples,
  and the good-sector split $+5$ (4 times), $-5$ (4 times) on $B = +1$.
- These are statements about one-particle waves in flat 4+4 space or in the
  frozen-coefficient model, which leaves out the hidden-direction terms of the
  author's field equation (an ASSUMPTION). How a positive quantum state space is
  built from them (and where that is possible) is the subject of the next notebooks
  of this chapter.
```

10.10 Line-by-line walk-through of Notebook 10a

The notebook has 18 code cells, In [1] to In [18]. This section explains every line of each of them. Python, the language of the notebooks, is read from top to bottom; a line that starts with `#` is a **comment** for the reader, which Python skips, and the text after `#` on a line of code is a comment too. Where a cell defines a function, the **docstring** (the text in triple quotes below the `def` line, which only describes the function) is left out of the quotations; it is printed in Section 10.9.

In [1], the set-up cell. Its first 247 lines are comments: they repeat, word for word, the run instructions of Section 10.8 (Python skips them; they are there so that the notebook carries its own instructions, so this comment block is different in every notebook), and end with the heading `# THE SET-UP (the same in every notebook of this book; it computes no physics)` between two lines of `=` signs. The code starts below that heading. The words "the same in every notebook of this book" in the heading are not exactly true; here is what is the same. The code below the heading is the same in all seven notebooks of this chapter, except for the line that sets `NOTEBOOK_ID`. In the whole book, that line differs from notebook to notebook, and the notebooks that run a Rust program also import `shutil` and `subprocess` and define one more helper, `rust_program`, which this chapter does not need.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module**, a collection of ready-made functions, so that the code can use it. The four modules come with Python. `json` reads and writes JSON files, the format of the Revision records; `os` gives access to the operating system; `textwrap` breaks a long text into lines. `from pathlib imp ort Path` takes only the name `Path` out of the module `pathlib`: a `Path` is the address of a file or a folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

matplotlib is the package that draws the figures; its drawing functions are loaded under the short name `plt`. `Image` and `display` come from IPython, the part of Jupyter that runs Python code; together they show a picture file below a cell.

```
NOTEBOOK_ID = "10a"  # this notebook: chapter 10, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text between quotes) `"10a"`. The figure files and the last printed line of the notebook use it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs each time it is called. `Path.cwd()` is the folder in which the notebook runs (Jupyter runs a notebook in the folder that holds it), and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with them. The `for` loop takes these folders one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds the file `Revision/textbook/requirements.txt` is the repository, and `return` hands it back to the caller. If no folder qualifies, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The two comment lines say what the next line does and why. That line calls the function and names its result `REPO`. It is never printed, because it differs from computer to computer while the printed output of a notebook must be the same everywhere. The three comment lines that follow explain the last line, which chooses the folder below which files are written. `os.environ` holds the **environment variables**, named texts that a program receives from the computer; `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set, and otherwise the repository folder (`str(REPO)` writes it as a text). When you run the notebook the variable is not set, so files go into the repository; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` is the complete path of a file of the repository; the notebook uses it to READ the Revision records. `output_file("Revision/...")` is the path at which to WRITE a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder of the file, and every missing folder above it, and does nothing if it already exists.

```
def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of this book: `textwrap.fill` breaks the text at blanks, and every line after the first starts with four blanks. `str(text)` turns a number or a list into text first.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings of matplotlib, so that a personal settings file on your computer cannot change the figures. `plt.rcParams.update({...})` then sets four of them: the size of a figure (7.0 by 4.2 inches), the size of the letters (10 points), and a faint grid behind every plot (`"grid.alpha": 0.3` makes it 30 percent opaque). The braces make a **dictionary**, a collection of pairs `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with the letter `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is the text `Revision/textbook/figures/10a.captions.json`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary, `{}` and a line end, into the captions file, which `save_figure` fills later; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` writes the same line end on every operating system, as the two comment lines above it say.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
```

```
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far (`len` is the number of entries); so the figures are numbered 1, 2, 3, and a cell that is run again keeps its numbers. The file name joins the notebook id, the number and the name, for example `10a_1_gamma4_c_and_b.png`. The three comment lines explain the options of the next line: `fig.savefig` writes the picture as a PNG file with 150 dots per inch (`dpi=150`), cuts away the empty margin (`bbox_inches="tight"`) and stores no program name in the file (`metadata={"Software": None}`), so that two runs write exactly the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time at the end of the cell. The caption is stored, and the whole dictionary of captions is written to the captions file; `json.dumps` turns the dictionary into JSON text with sorted keys. `display(Image(...))` shows the saved picture below the cell, with a label that the book's tools read, and the last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list**, an ordered collection written in square brackets. `check` is the function behind every check of the book. `condition` is a truth value, `True` or `False`. If it is false, `raise AssertionError(...)` stops the notebook with an error message that names the check (an `if` statement is used instead of Python's `assert`, because Python started with the option O, for optimise, would skip an `assert`). If it is true, the name is appended to `PASSED` and the line PASS name is printed; when the optional third argument `record` names a Revision record, a second line says which record and check the result reproduces.

```
def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))
```

```
def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; the unit is added only when one is given (`a if condition else b` is `a` when the condition holds and `b` otherwise). `all_checks_passed` prints the last line of the notebook with the number of checks that passed. The last statement prints the single output line of In [1]. Two strings written next to each other, as here, are joined into one.

In [2], the gammas and the Clifford relation.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices
import sympy as sp  # exact algebra with symbols
```

Three more modules of Python are loaded, and the two mathematical packages of the book: numpy (short name `np`) computes with arrays of numbers, sympy (short name `sp`) computes exactly with symbols.

```
REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"
```

`REPORT_CHECKS` starts as an empty dictionary; it will hold, for every report file that the notebook cites, the verdicts of the report's checks, stored under the check names. `record_says_pass(record)` answers one question: does the cited record still say what the notebook claims? A record name such as `"Revision/theory/reports/python-field-theory.json, check B_properties"` is a file name and a check name joined by the text `, check `. `record.partition(", check ")` cuts the record name at the first occurrence of that text into three pieces: the part before it (`path`), the text itself (`separator`) and the part after it (`check_name`). If the text does not occur, `separator` is empty and the record names a data entry of a file, such as `"Revision/algebra/gammas.json, entry B"`, which the notebook reads and compares itself; the answer is then True. Otherwise the report file is

read, once: `json.loads(...)["checks"]` is the list of its checks, each a dictionary with the keys `name`, `verdict` and `detail`, and the dictionary comprehension stores every verdict under its check name in capital letters (`.upper()`; some reports write `pass` in small letters). The answer is True only if a check of that name exists and its verdict is `PASS`; `.get` gives `None` for a missing name, and `None == "PASS"` is False.

```
def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

`check_record` first asks `record_says_pass`. If the answer is False, `raise AssertionError(...)` stops the notebook with an error message that names the record, in the same way as a failed check: the notebook never prints that it reproduces a record check that has been renamed, removed or turned to FAIL. Otherwise `check_record` does what `check(condition, name, record=record)` does, but prints the PASS line and the reproduces line in one piece. `io.StringIO()` is a **text buffer**, a piece of memory that collects printed text. Inside the `with` block everything that is printed goes into the buffer instead of the screen; `check` prints its two lines there (or stops the notebook if the condition is false). Then `sys.stdout.write` sends the collected text to the screen at once. Jupyter delivers printed text in pieces whose boundaries depend on timing; printing the two lines as one piece keeps the stored output of the notebook the same in every run.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
# gamma[a] is the matrix gamma^(x_a) of the coordinate x_a, a = 1, ..., 8.
gamma = {a: np.array(fixture["gamma"][a], dtype=int) for a in range(8)}
eta = {a: fixture["eta"][a] for a in range(8)}  # +1 space-like, -1 time-like
identity = np.eye(16, dtype=int)
say(f"eta = {[eta[a] for a in range(8)]} for x0, ..., x7")
```

`read_text` reads the record file as text, and `json.loads` turns that text into Python objects: `fixture` is a dictionary whose keys are the names stored in the record. `fixture["gamma"]` is a list of eight matrices, each a list of 16 rows of 16 whole numbers, in the order $x_0, \ldots, x_7$; Python counts list positions from 0, like the author's coordinates, so the matrix of x_a is at position `a`. The **dictionary comprehension** `{a: ... for a in range(8)}` builds a dictionary in one line: for $a = 0, \ldots, 7$ (`range(8)` runs from 0 up to, but not including, 8) it stores the matrix as a numpy array of whole numbers (`dtype=int`), so that every product below is exact. `eta` stores the eight signs of the frame metric in the same way, and `np.eye(16, dtype=int)` is the identity matrix I_{16}. The `say` line prints the list of the eight signs; its output, `eta = [1, 1, 1, 1, -1, -1, -1, -1] for x0, ..., x7`, is the frame metric η of the notation paragraph of Section 10.1.

```
clifford_ok = all(
    np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                   2 * (eta[a] if a == b else 0) * identity)
    for a in range(8) for b in range(8))  # all 64 pairs (a, b)
check(clifford_ok,
      "the 64 Clifford relations hold exactly (eta = diag(+,+,+,+,-,-,-,-))")
```

In Python the sign `@` multiplies two matrices. For each of the $8 \times 8 = 64$ pairs (a, b) the expression compares $\gamma^{(x_a)}\gamma^{(x_b)} + \gamma^{(x_b)}\gamma^{(x_a)}$ with $2\eta_{ab} I_{16}$ (the factor is η_{aa} when $a = b$ and 0 otherwise); `np.array_equal` is true only when all 256 entries agree. `all(...)` is true when the comparison holds for every pair. The check prints PASS: the Clifford relation of Section 10.1 holds exactly.

In [3], the matrices C and B.

```
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4), a complex 16 x 16 matrix
B_file = np.array(fixture["B"]["re"]) + 1j * np.array(fixture["B"]["im"])
check_record(np.array_equal(B, B_file),
             "B = -i C gamma^(x4) equals the matrix B of the record",
             record="Revision/algebra/gammas.json, entry B")
```

The first two lines build $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ and $B = -iC\gamma^{(x_4)}$; Python writes the imaginary unit i as `1j`. The record stores B too, its real and imaginary parts as two tables of numbers; `B_file` puts them together. The check compares the two matrices entry by entry and reproduces the record's entry `B`.

```
purely_imaginary = np.all(B.real == 0)  # every entry is 0, +i or -i
hermitian = np.array_equal(B, B.conj().T)  # B^dagger = B
squares_to_one = np.array_equal(B @ B, np.eye(16))  # B^2 = I
trace_B = np.trace(B)  # the sum of the diagonal entries
eigenvalues_B = np.linalg.eigvalsh(B)  # the 16 real eigenvalues, sorted
n_plus = int(np.sum(eigenvalues_B > 0.5))  # how many are +1
n_minus = int(np.sum(eigenvalues_B < -0.5))  # how many are -1
```

These lines test the properties (B2) to (B5) of Section 10.2. `B.real == 0` is a table of truth values, and `np.all` is true when all are true. `B.conj().T` is the conjugate transpose $B^\dagger$ (`.conj()` conjugates every entry, `.T` transposes). `np.trace` is the trace. `np.linalg.eigvalsh` computes the eigenvalues of a Hermitian matrix, which are real, sorted from the smallest; `eigenvalues_B > 0.5` marks those that are $+1$, `np.sum` counts the marks, and `int` writes the count as an ordinary whole number.

```
report("trace of B", int(round(abs(trace_B))))
report("eigenvalues of B equal to +1 and to -1", f"{n_plus} and {n_minus}")
check_record(purely_imaginary and hermitian and squares_to_one and trace_B == 0
             and (n_plus, n_minus) == (8, 8),
             "B is imaginary and Hermitian, B^2 = I, tr B = 0, signature (8, 8)",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "B_properties")
```

The two RESULT lines print the trace, 0, and the counts, 8 and 8. The check requires all four properties and the signature (8,8), and reproduces the check `B_properties` of `python-field-theory.json`.

In [4], a heat map of three matrices.

```
from matplotlib.colors import LinearSegmentedColormap  # colour scales
```

```
BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
# A diverging colour scale: dark blue (negative), light grey (zero), red (positive).
DIVERGING = LinearSegmentedColormap.from_list(
    "blue_grey_red", ["#184f95", "#f0efec", "#e34948"])
# A sequential colour scale for sizes: almost white (zero) to dark blue (large).
SEQUENTIAL = LinearSegmentedColormap.from_list(
    "white_blue", ["#fcfcfb", "#86b6ef", "#184f95"])
```

A colour is written as a text `"#rrggbb"`, three two-digit numbers in base 16 for its red, green and blue parts. The first line of assignments gives four colours four names at once (Python assigns the values on the right to the names on the left in order); the colours stay distinguishable for colour-blind readers. A **colour scale** turns a number into a colour: `DIVERGING` runs from dark blue for -1 through light grey for 0 to red for $+1$, and `SEQUENTIAL` from almost white for 0 to dark blue for large values. `from_list` builds a scale that blends smoothly between the listed colours.

```
def draw_matrix(ax, matrix, title, cmap=DIVERGING, vmin=-1.0, vmax=1.0):
    image = ax.imshow(matrix, cmap=cmap, vmin=vmin, vmax=vmax)
    size = matrix.shape[0]
    ticks = list(range(0, size, 3))  # every third row and column is labelled
    ax.set_xticks(ticks, [str(t + 1) for t in ticks])
    ax.set_yticks(ticks, [str(t + 1) for t in ticks])
    ax.grid(False)  # no grid lines on top of the squares
    ax.set_title(title)
    return image
```

A **heat map** draws a matrix as a grid of coloured squares, one for each entry. `ax` is one drawing area (matplotlib calls it an axes); `ax.imshow` draws the matrix with the colour scale `cmap`, where `vmin` and `vmax` are the numbers that get the two end colours. `matrix.shape[0]` is the number of rows. The tick marks are put at every third row and column, labelled from 1 (the computer counts from 0, the book from 1). The grid is switched off because it would cut through the squares. The function returns the drawn image, which a colour bar needs.

```
# A purely imaginary B = i Y (Y real) is Hermitian exactly when -i Y^T = i Y,
# that is when Y^T = -Y: the imaginary part of B must be antisymmetric.
one_per_row = all(np.count_nonzero(M, axis=1).tolist() == [1] * 16
                  and np.count_nonzero(M, axis=0).tolist() == [1] * 16
                  for M in (gamma[4], C, B.imag))  # signed permutation matrices
check(np.array_equal(gamma[4].T, -gamma[4]) and np.array_equal(C.T, C)
      and np.array_equal(B.imag.T, -B.imag) and one_per_row,
      "gamma^(x4) and Im B are antisymmetric, C is symmetric, all signed permutations")
```

`np.count_nonzero(M, axis=1)` counts the nonzero entries in each row of M and `axis=0` in each column; `.tolist()` turns the result into a list, and `[1] * 16` is the list of sixteen ones. So `one_per_row` is true when each of the three matrices $\gamma^{(x_4)}$, C and the imaginary part of B has exactly one nonzero entry in every row and every column. The check also tests that $\gamma^{(x_4)}$ is antisymmetric ($M^T = -M$), C symmetric, and the imaginary part of B antisymmetric. The two comment lines at the top give the reason for the last fact: if $B = iY$ with Y real, then $B^\dagger = -iY^T$, and $B^\dagger = B$ means $Y^T = -Y$.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
draw_matrix(axes[0], gamma[4], "$\\gamma^{(x_4)}$ (real, antisymmetric)")
draw_matrix(axes[1], C, "$C$ (real, symmetric)")
image = draw_matrix(axes[2], B.imag, "imaginary part of $B = -iC\\gamma^{(x_4)}$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry")
save_figure(fig, "gamma4_c_and_b",
...)
```

(The caption text, the third argument of `save_figure`, is shortened here to three dots; it is printed in full under the figure in Section 10.9.) `plt.subplots(1, 3, ...)` makes a figure with one row of three drawing areas, 11 by 4 inches. The titles are written in LaTeX, the mathematical notation of the book; inside a Python string a backslash is written twice. `fig.colorbar` adds the colour bar on the right, shared by the three maps. Figure 1 of Notebook 10a shows the result: in each of the three heat maps every row and every column has exactly one coloured square; C is the same after reflection in the diagonal, while $\gamma^{(x_4)}$ and the imaginary part of B change colour under that reflection. This is the picture of the table of B in Section 10.2.

In [5], the mode Hamiltonian as numbers.

```
def mode_hamiltonian(m, k):
    h = -1j * m * gamma[4]
    for a, k_a in k.items():
        h = h - k_a * (gamma[4] @ gamma[a])
    return h

def frequency_squared(m, k):
    return m ** 2 + sum(eta[a] * k_a ** 2 for a, k_a in k.items())
```

`mode_hamiltonian(m, k)` builds $h = -im\gamma^{(x_4)} - \gamma^{(x_4)} \sum_a k_a \gamma^{(x_a)}$ of Section 10.3; `k` is a dictionary that gives the momenta of some of the directions, for example `{1: 0.3, 5: 0.4}`, and `k.items()` runs through its pairs (direction, momentum). Directions that are not listed have momentum 0. `frequency_squared(m, k)` returns $w^2 = m^2 + \sum_a \eta_{aa} k_a^2$ (`**` is the power in Python): the space-like momenta enter with $+$, the extra-time momenta with $-$.

```
example = {0: 1.3, 1: 0.3, 2: -1.1, 3: 0.7, 5: 0.4, 6: 0.2, 7: -0.9}  # any numbers
h_example = mode_hamiltonian(1.7, example)
w2_example = frequency_squared(1.7, example)
report("w^2 for m = 1.7 and the example momenta", f"{w2_example:.6f}")
error = np.max(np.abs(h_example @ h_example - w2_example * np.eye(16)))
report("largest entry of h^2 - w^2 I (rounding only)", f"{error:.1e}")
check(error < 1e-12, "numerical example: h^2 = w^2 I at one generic point")
```

For the mass 1.7 and momenta along all seven slice directions the cell computes $w^2 = 2.89 + (0.09 + 1.21 + 0.49 + 1.69) - (0.16 + 0.04 + 0.81) = 5.36$, printed with six decimals (`:.6f`), and the largest size of an entry of $h^2 - w^2 I_{16}$ (`np.abs` takes sizes, `np.max` the largest), printed in the exponent form `8.9e-16`, which means 8.9×10^{-16}: only rounding. numpy computes with about 16 significant digits, so its checks allow a tiny tolerance.

In [6], the same, exactly.

```
g = {a: sp.Matrix(fixture["gamma"][a]) for a in range(8)}  # exact gammas
C_exact = g[0] * g[1] * g[2] * g[3]
B_exact = -sp.I * C_exact * g[4]
m = sp.Symbol("m", real=True)  # the mass: any real number
k_sym = {a: sp.Symbol(f"k{a}", real=True) for a in (0, 1, 2, 3, 5, 6, 7)}
```

The same gammas are stored as sympy matrices, which hold exact whole numbers; for sympy matrices `*` is the matrix product and `sp.I` is the imaginary unit. `sp.Symbol("m", real=True)` is a letter m that stands for any real number, and `k_sym` holds the seven letters $k_1, k_2, k_3, k_5, k_6, k_7, k_0$. A computation with these letters holds for all their values at once: it is a proof.

```
def mode_hamiltonian_exact(mass, k):
    h = -sp.I * mass * g[4]
    for a, k_a in k.items():
        h = h - k_a * g[4] * g[a]
    return h

zero = sp.zeros(16, 16)
h_sym = mode_hamiltonian_exact(m, k_sym)
w2_sym = m ** 2 + sum(eta[a] * k_sym[a] ** 2 for a in k_sym)
say(f"w^2 = {w2_sym}")
```

The function builds h exactly; `h_sym` is h for the letters, `w2_sym` the expression w^2, which the cell prints: `k0**2 + k1**2 + k2**2 + k3**2 - k5**2 - k6**2 - k7**2 + m**2` (sympy writes the power as `**`).

```
square_ok = (h_sym * h_sym - w2_sym * sp.eye(16)).applyfunc(sp.expand) == zero
check_record(square_ok, "exact: h^2 = w^2 I for all real m and k",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_one_particle_flat_dispersion")
krein_ok = (B_exact * h_sym - h_sym.H * B_exact).applyfunc(sp.expand) == zero
check_record(krein_ok,
             "exact: B h = h^dagger B for all real m and k (Krein self-adjoint)",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "mode_hamiltonian_B_selfadjoint_dispersion")
```

`applyfunc(sp.expand)` multiplies out every entry of a matrix, so that an entry that is zero for all values of the letters becomes literally 0; comparing with the zero matrix then decides the identity. The first check proves $h^2 = w^2 I_{16}$ (Section 10.4) and reproduces the Wolfram check `Q_one_particle_flat_dispersion`; the second proves $Bh = h^\dagger B$ (`.H` is sympy's conjugate transpose; the letters are declared real, so their conjugates are themselves) and reproduces the sympy record check `mode_hamiltonian_B_selfadjoint_dispersion`.

In [7], where h stops being Hermitian.

```
not_hermitian_part = (h_sym - h_sym.H).applyfunc(sp.expand)
commutator = (B_exact * h_sym - h_sym * B_exact).applyfunc(sp.expand)
symbols_1 = sorted(str(s) for s in not_hermitian_part.free_symbols)
```

```
symbols_2 = sorted(str(s) for s in commutator.free_symbols)
say(f"symbols in h - h^dagger: {symbols_1}")
say(f"symbols in B h - h B:    {symbols_2}")
```

The cell computes the exact matrices $h - h^\dagger$ and $Bh - hB$. `.free_symbols` is the set of the letters that occur in an expression; `sorted(str(s) for s in ...)` writes them as a sorted list of names (a set has no fixed order, a sorted list has). Both printed lists are `['k5', 'k6', 'k7']`: only the extra-time momenta make h non-Hermitian and make it fail to commute with B, as Section 10.4 derived from $h = h_H + h_A$.

```
good_sector = {k_sym[5]: 0, k_sym[6]: 0, k_sym[7]: 0}  # no extra-time momentum
check_record(symbols_1 == ["k5", "k6", "k7"]
             and not_hermitian_part.subs(good_sector) == zero,
             "exact: h is Hermitian exactly in the good sector k5 = k6 = k7 = 0",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "mode_hamiltonian_good_sector")
check_record(symbols_2 == ["k5", "k6", "k7"]
             and commutator.subs(good_sector) == zero,
             "exact: B h = h B exactly in the good sector",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_spectrum_and_B_sectors")
```

`.subs(good_sector)` replaces k_5, k_6, k_7 by 0. The two checks require that only these letters occur and that both matrices vanish when they are 0, and reproduce the two record checks named.

In [8], the squared frequency against the extra-time momentum.

```
k5_values = np.linspace(0.0, 3.0, 301)  # 301 values of k5 from 0 to 3
fig, ax = plt.subplots()
for k_s, colour in ((0.0, BLUE), (1.0, ORANGE), (2.0, GREEN)):
    w2_curve = [frequency_squared(1.0, {1: k_s, 5: k5}) for k5 in k5_values]
    ax.plot(k5_values, w2_curve, color=colour, linewidth=2,
            label=f"$k_s = {k_s:.0f}$")
    crossing = np.sqrt(1.0 + k_s ** 2)  # where w^2 = 0
    ax.plot([crossing], [0.0], "o", color=colour, markersize=8)
```

`np.linspace(0.0, 3.0, 301)` is a list of 301 equally spaced numbers from 0 to 3. For the mass 1 and three space-like momenta $k_s = 0, 1, 2$ (put along x_1) the loop computes $w^2 = 1 + k_s^2 - k_5^2$ at every k_5 (a **list comprehension** `[... for k5 in k5_values]` builds the list in one line), draws it as a line (`ax.plot(x, y, ...)`), and marks with a dot (`"o"`) the point $k_5 = \sqrt{1 + k_s^2}$ where $w^2 = 0$.

```
ax.axhline(0.0, color=GREY, linewidth=1)
ax.text(0.1, 3.0, "$w^2 > 0$: real frequency, the wave oscillates", color=GREY)
ax.text(0.1, -6.0, "$w^2 < 0$: imaginary frequency, the wave grows", color=GREY)
ax.set_xlabel("momentum $k_5$ along the extra time $x_5$")
ax.set_ylabel("$w^2 = m^2 + k_s^2 - k_5^2$")
ax.set_title("The squared frequency of a plane wave, $m = 1$")
ax.legend(title="space-like momentum")
save_figure(fig, "frequency_squared",
...)
```

`axhline` draws a horizontal line at height 0; `ax.text` writes a text at a point of the plot; the labels name the axes; `ax.legend` lists the three curves with their labels. Figure 2 of Notebook 10a shows three downward parabolas, one for each k_s, each crossing zero at its dot: above the grey line the wave oscillates, below it the wave grows. A larger space-like momentum moves the crossing to the right, but every curve crosses: a large enough extra-time momentum always wins.

```
check(all(abs(frequency_squared(1.0, {1: k_s, 5: np.sqrt(1.0 + k_s ** 2)})) < 1e-12
          for k_s in (0.0, 1.0, 2.0)),
      "w^2 = 0 exactly at k5 = sqrt(m^2 + k_s^2)")
```

The check confirms that w^2 vanishes at the three dots, up to rounding.

In [9], the eigenvalues as k_5 grows.

```
real_parts, imaginary_parts, worst = [], [], 0.0
for k5 in k5_values:
    eigenvalues = np.linalg.eigvals(mode_hamiltonian(1.0, {5: k5}))
    real_parts.append(np.sort(eigenvalues.real))
    imaginary_parts.append(np.sort(eigenvalues.imag))
```

For each of the 301 values of k_5 (mass 1, no other momentum) `np.linalg.eigvals` computes the 16 eigenvalues of h, which may be complex numbers; their real parts and their imaginary parts are sorted and stored for the figure.

```
    w2 = 1.0 - k5 ** 2
    if abs(w2) > 0.05:  # away from the point where h cannot be diagonalised
        w = np.sqrt(complex(w2))  # sqrt of a negative number is imaginary
        predicted = np.array([w] * 8 + [-w] * 8)
        # compare the sorted real parts and the sorted imaginary parts separately
        worst = max(worst,
                    np.max(np.abs(np.sort(eigenvalues.real) - np.sort(predicted.real))),
                    np.max(np.abs(np.sort(eigenvalues.imag) - np.sort(predicted.imag))))
report("largest difference from the formula +-w (8 times each)", f"{worst:.1e}")
check(worst < 1e-10, "the 16 eigenvalues of h are +w and -w, eight times each")
```

The predicted eigenvalues are $+w$ eight times and $-w$ eight times; `complex(w2)` makes w^2 a complex number, so that `np.sqrt` of a negative number gives the imaginary $i\kappa$ instead of an error. At $k_5 = 1$ exactly, $h^2 = 0$ but $h \neq 0$: such a matrix has no basis of eigenvectors, and numerical eigenvalues are then only accurate to about 10^{-8}; points with $|w^2| < 0.05$ are therefore left out of the comparison. `worst` keeps the largest difference seen; it is printed as `3.6e-15`, so the formula holds to rounding.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.0), sharex=True)
axes[0].plot(k5_values, np.array(real_parts), color=BLUE, linewidth=2)
axes[1].plot(k5_values, np.array(imaginary_parts), color=ORANGE, linewidth=2)
for ax, what in ((axes[0], "real part"), (axes[1], "imaginary part")):
    ax.axvline(1.0, color=GREY, linestyle=":", linewidth=1)
    ax.set_xlabel("momentum $k_5$ along the extra time $x_5$ ($m = 1$)")
    ax.set_ylabel(f"{what} of the eigenvalues of $h$")
axes[0].set_title("oscillation: real frequencies $\\pm w$")
```

```
axes[1].set_title("growth: imaginary frequencies $\\pm i\\kappa$")
save_figure(fig, "eigenvalue_flow",
...)
```

`np.array(real_parts)` is a table with one row per k_5 and 16 columns; `plot` draws each column as a curve. `sharex=True` gives both panels the same horizontal axis, and `axvline` draws a dotted vertical line at $k_5 = 1$. Figure 3 of Notebook 10a shows the real parts $\pm\sqrt{1 - k_5^2}$ closing in to 0 at $k_5 = 1$ and staying 0 afterwards, while the imaginary parts are 0 before and open up as $\pm\sqrt{k_5^2 - 1}$ afterwards: oscillation turns into growth. Each curve carries eight eigenvalues on top of each other.

In [10], three functions for the Krein inertia.

```
def orthonormal_basis(P):
    basis = []
    for column in P.T:  # the columns of P, in order
        v = column.astype(complex)
        for _ in range(2):  # the second pass removes rounding errors
            for e in basis:
                v = v - (e.conj() @ v) * e  # remove the part of v along e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:  # v is not a combination of the earlier columns
            basis.append(v / length)
    return np.array(basis).T  # the basis vectors as the columns of a matrix
```

This is the **Gram-Schmidt method**. Two columns are **orthonormal** when each has length 1 and $e^\dagger v = 0$ between them. Going through the columns of P in order (`P.T` lists the columns of P as rows), the function removes from each column v its part along every basis vector e found so far ($e^\dagger v$ is the size of that part, and `e.conj() @ v` computes it), and keeps what is left, divided by its length $\sqrt{v^\dagger v}$, if anything is left. The removal is done twice, because the first pass leaves tiny rounding errors. A column that is a combination of the earlier ones leaves nothing (a length below 10^{-8}) and is skipped. The result is a matrix whose columns are an orthonormal basis of the range of P; `for _ in range(2)` repeats a block twice without needing the counter.

```
def eigenspace(m, k, sign):
    h = mode_hamiltonian(m, k)
    w = np.sqrt(complex(frequency_squared(m, k)))  # w, or i kappa when w^2 < 0
    P = (np.eye(16) + sign * h / w) / 2  # the projector P_+ or P_-
    return orthonormal_basis(P)
```

`eigenspace(m, k, sign)` builds the projector $P_\pm = \frac{1}{2}(I_{16} \pm h/w)$ of Section 10.5 and returns an orthonormal basis of its range, the eigenspace of $+w$ (`sign = +1`) or $-w$ (`sign = -1`). For $w^2 < 0$ the number w is $i\kappa$, and the same formula gives the eigenspaces of $\pm i\kappa$.

```
def krein_inertia(V):
    G = V.conj().T @ B @ V  # the Krein form on the span of the columns of V
    values = np.linalg.eigvalsh(G)
    nonzero = np.abs(values[np.abs(values) > 1e-8])
    counts = (int(np.sum(values > 1e-8)), int(np.sum(values < -1e-8)),
              int(np.sum(np.abs(values) <= 1e-8)))
    return counts, (float(nonzero.min()) if nonzero.size else None)
```

`krein_inertia(V)` forms the Gram matrix $G = V^\dagger B V$ of the columns of V (Section 10.5) and counts its positive, negative and zero eigenvalues, "zero" meaning smaller in size than 10^{-8}. It returns the triple (p, n, z) and, in addition, the smallest size of a nonzero eigenvalue (or `None`, Python's word for "nothing", when all are zero), to show that no eigenvalue lies near the borderline 10^{-8}. `values[np.abs(values) > 1e-8]` picks out the eigenvalues that are not zero.

In [11], the eight recorded samples.

```
pairing = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                     .read_text(encoding="utf-8"))
samples = pairing["data"]["one_particle_flat"]["samples"]
all_agree = True
say("   m  nonzero momenta         w      dims   inertia(+w)  inertia(-w)")
```

The cell reads the pairing record and takes the list of eight samples stored under `data`, `one_part icle_flat`, `samples`. Each sample is a dictionary with a mass `m`, a list `k` of eight momenta $(k_0, \ldots, k_7)$ (the entry k_4 is not used), the frequency `w` as text, the dimensions of the two eigenspaces and their Krein inertia. The `say` line prints the header of the table.

```
for sample in samples:
    m_value, k_list = sample["m"], sample["k"]
    k = {a: k_list[a] for a in (0, 1, 2, 3, 5, 6, 7) if k_list[a] != 0}
    # "Sqrt[2]" (Wolfram notation) -> the number sqrt(2)
    w_recorded = float(sp.sympify(sample["w"].replace("Sqrt[", "sqrt(")
                                  .replace("]", ")")))
    w = np.sqrt(frequency_squared(m_value, k))
```

For each sample the loop builds the dictionary of the nonzero momenta (the `if` inside the comprehension skips the zeros). The record writes the frequency in the notation of the Wolfram Language, for example `Sqrt[2]`; `.replace` turns it into the sympy notation `sqrt(2)`, `sp.sympify` reads that text as an exact number, and `float` gives its decimal value. `w` is the frequency recomputed from m and k.

```
    found = []
    for sign in (+1, -1):
        V = eigenspace(m_value, k, sign)
        counts, _ = krein_inertia(V)
        found.append((V.shape[1], counts))
```

For both eigenspaces the loop computes a basis, its dimension (`V.shape[1]`, the number of columns) and its Krein inertia; the underscore receives the second result of `krein_inertia`, which is not needed here.

```
    agree = (abs(w - w_recorded) < 1e-12
             and found[0][0] == sample["dim_plus_w"]
             and found[1][0] == sample["dim_minus_w"]
             and list(found[0][1][:2]) == sample["B_inertia_plus_w"]
             and list(found[1][1][:2]) == sample["B_inertia_minus_w"]
             and found[0][1][2] == 0 and found[1][1][2] == 0)
    all_agree = all_agree and agree
```

`agree` requires the frequency, both dimensions and both inertias to equal the recorded ones, and no zero eigenvalue (`[:2]` takes the first two numbers of a triple, `[2]` the third). `all_agree` stays true only if every sample agrees.

```
    momenta = ", ".join(f"k{a}={v}" for a, v in k.items()) or "none"
    say(f"{m_value:4d}  {momenta:22s} {w:7.4f}   {found[0][0]},{found[1][0]}    "
        f"{found[0][1][:2]}       {found[1][1][:2]}")
check_record(all_agree,
             "all 8 recorded samples: w, dimensions 8 and 8, Krein inertia (4, 4)",
             record="Revision/pairing/pairing-theory.json, data one_particle_flat")
```

`", ".join(...)` writes the momenta as one text separated by commas, or the word `none` when there is no momentum (an empty text counts as false, so `or` takes the second value). The format codes fix the widths of the columns: `:4d` a whole number in 4 places, `:22s` a text in 22 places, `:7.4f` a decimal number in 7 places with 4 decimals. The printed table has one line per sample: for the masses ± 2 with $(k_0, k_1, k_2) = (4, 1, 2)$ the frequency is $5 = \sqrt{4 + 16 + 1 + 4}$; for ± 3 at rest it is 3; for ± 1 with $k_1 = 1$ it is $1.4142 = \sqrt{2}$; for ± 2 with the extra-time momentum $k_5 = 1$ it is $1.7321 = \sqrt{3}$. Every line shows the dimensions 8 and 8 and the inertia (4, 4) on both eigenspaces, the same for $+m$ and $-m$, and the check reproduces the record's data `one_particle_flat`.

In [12], one more real-frequency sample and the neutral eigenspaces.

```
sample_3 = {0: 2, 1: 2}
inertias_3 = [krein_inertia(eigenspace(1, sample_3, s))[0] for s in (+1, -1)]
report("w for m = 1, k0 = 2, k1 = 2", f"{np.sqrt(frequency_squared(1, sample_3)):.6f}")
say(f"inertia of the +w and -w eigenspaces: {inertias_3}")
check_record(inertias_3 == [(4, 4, 0), (4, 4, 0)],
             "m = 1, k0 = 2, k1 = 2 (w = 3): inertia (4, 4) on both eigenspaces",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_Krein_inertia")
```

The sympy pairing verifier uses the sample $m = 1$, $k_1 = 2$, $k_0 = 2$, so $w = \sqrt{1 + 4 + 4} = 3$, printed as `3.000000`. The inertia of both eigenspaces is printed as `[(4, 4, 0), (4, 4, 0)]` and reproduces the check `Q.one_particle_Krein_inertia`.

```
neutral_ok = True
for k in ({5: 2}, {1: 1, 5: 2}):
    spaces = [eigenspace(1, k, s) for s in (+1, -1)]
    inertias = [krein_inertia(V)[0] for V in spaces]
    say(f"m = 1, momenta {k}: w^2 = {frequency_squared(1, k)}, dimensions "
        f"{[V.shape[1] for V in spaces]}, inertia {inertias}")
    neutral_ok = neutral_ok and inertias == [(0, 0, 8), (0, 0, 8)]
```

Two imaginary-frequency samples of the record: $m = 1$ with $k_5 = 2$ ($w^2 = 1 - 4 = -3$) and with $k_1 = 1$, $k_5 = 2$ ($w^2 = 1 + 1 - 4 = -2$). The printed lines show dimensions 8 and 8 and the inertia $(0, 0, 8)$ for both eigenspaces: they are Krein-neutral, as the last part of the proof of Theorem 10.1 says.

```
h_zero = mode_hamiltonian(1, {5: 1})  # w^2 = 1 - 1 = 0
rank_h = int(np.linalg.matrix_rank(h_zero))
```

```
nilpotent = np.max(np.abs(h_zero @ h_zero)) < 1e-12  # h^2 = 0
range_neutral = np.max(np.abs(h_zero.conj().T @ B @ h_zero)) < 1e-12
say(f"m = 1, k5 = 1: w^2 = 0, h^2 = 0: {nilpotent}, rank of h = {rank_h}, "
    f"range of h neutral: {range_neutral}")
check_record(neutral_ok and nilpotent and rank_h == 8 and range_neutral,
             "imaginary and zero frequencies: the eigenspaces are Krein-neutral",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_complex_frequency_Krein_neutral")
```

The zero-frequency sample $m = 1$, $k_5 = 1$: `np.linalg.matrix_rank` is the **rank** of a matrix, the number of its independent columns. The cell checks $h^2 = 0$, rank 8, and that $h^\dagger B h = 0$, which says that the columns of h (and so its whole range) have zero Krein form with each other. The printed line shows `True`, 8 and `True`, and the check reproduces the record.

In [13], steps (i) and (ii) of the proof, exactly.

```
w = sp.Symbol("w", positive=True)
I16 = sp.eye(16)

def replace_w_squared(matrix):
    return matrix.applyfunc(lambda e: sp.expand(sp.expand(e).subs(w ** 2, w2_sym)))
```

`w` is now a positive letter. A **lambda** is a function written in one line without a name: `lambda e: ...` takes an entry `e`, multiplies it out, replaces every w^2 by $m^2 + k_s^2 - k_t^2$ (the expression `w2_sym` of In [6]) and multiplies out again. `replace_w_squared` does this for every entry of a matrix.

```
step_i_a = replace_w_squared((w * I16 + h_sym.H) * B_exact * (w * I16 - h_sym))
step_i_b = replace_w_squared((w * I16 + h_sym.H) * B_exact * (w * I16 + h_sym)
                             - 2 * w * B_exact * (w * I16 + h_sym))
check_record(step_i_a == zero and step_i_b == zero,
             "exact step (i): 4 w^2 P+^dagger B P- = 0 and P+^dagger B P+ = B P+",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_Krein_inertia_proof")
```

`step_i_a` is $(wI + h^\dagger)B(wI - h) = 4w^2 P_+^\dagger B P_-$, and `step_i_b` is $(wI + h^\dagger)B(wI + h) - 2wB(wI + h)$, which is $4w^2(P_+^\dagger B P_+ - B P_+)$. Both vanish exactly, which is step (i) of Theorem 10.1, and the check reproduces `Q.one_particle_Krein_inertia_proof`.

```
trace_B_h = sp.expand((B_exact * h_sym).trace())
say(f"exact: tr B = {B_exact.trace()}, tr(B h) = {trace_B_h}")
check(B_exact.trace() == 0 and trace_B_h == 0,
      "exact step (ii): tr B = tr(B h) = 0, so tr(B P+) = tr(B P-) = 0")
```

The exact traces of B and of Bh are printed as 0 and 0; with them $\mathrm{tr}(BP_\pm) = 0$, step (ii).

In [14], step (iii) at work: a scan across the threshold.

```
threshold = np.sqrt(1.25)
scan = [k5 for k5 in np.linspace(0.0, 2.5, 251) if abs(k5 - threshold) > 0.02]
```

```
counts_scan, margins = [], []
for k5 in scan:
    counts, margin = krein_inertia(eigenspace(1.0, {1: 0.5, 5: k5}, +1))
    counts_scan.append(counts)
    if margin is not None:
        margins.append(margin)
```

For $m = 1$ and $k_1 = 0.5$ the frequency is real while $k_5 < \sqrt{1 + 0.25} = \sqrt{1.25} \approx 1.118$. The list `scan` holds 251 values of k_5 from 0 to 2.5 without those closer than 0.02 to the threshold (there the two eigenspaces merge and the numbers become inaccurate). For each value the loop stores the inertia of the $+w$ eigenspace and the smallest size of a nonzero Gram eigenvalue.

```
below = [c for k5, c in zip(scan, counts_scan) if k5 < threshold]
above = [c for k5, c in zip(scan, counts_scan) if k5 > threshold]
report("points below and above the threshold", f"{len(below)} and {len(above)}")
report("smallest nonzero Gram eigenvalue below the threshold", f"{min(margins):.4f}")
check(set(below) == {(4, 4, 0)} and set(above) == {(0, 0, 8)},
      "scan: inertia (4, 4) at every real frequency, (0, 0, 8) at every imaginary "
      "one")
```

`zip` pairs each k_5 with its inertia. The cell prints 110 points below and 137 above the threshold, and the smallest nonzero Gram eigenvalue below the threshold, 0.2225: well away from 0, as step (iii) requires. `set(below)` is the set of the different inertias found below the threshold; the check requires it to be the single triple $(4, 4, 0)$, and above the threshold the single triple $(0, 0, 8)$.

```
counts_array = np.array(counts_scan)  # one row (positive, negative, zero) per k5
fig, ax = plt.subplots()
width = 0.0105  # a little wider than the step 0.01 between the k5 values (no gaps)
# Stacked bars: the blue part (positive directions) starts at 0, the orange part
# (negative directions) on top of it, the green part (neutral) on top of both.
ax.bar(scan, counts_array[:, 0], width=width, color=BLUE,
       label="positive charge $u^\\dagger B u > 0$")
ax.bar(scan, counts_array[:, 1], width=width, bottom=counts_array[:, 0],
       color=ORANGE, label="negative charge $u^\\dagger B u < 0$")
ax.bar(scan, counts_array[:, 2], width=width,
       bottom=counts_array[:, 0] + counts_array[:, 1], color=GREEN,
       label="neutral (the form vanishes)")
```

`counts_array[:, 0]` is the first column of the table (the positive counts), and so on. `ax.bar` draws one thin bar at each k_5 (the variable `width`, 0.0105, is a little more than the step 0.01 between neighbouring values of k_5, so that the bars touch); as the two comment lines say, `bottom=` stacks the second kind of bar on top of the first and the third on top of both, so each full bar has the height 8, split by colour into positive, negative and neutral directions.

```
ax.axvline(threshold, color=GREY, linestyle=":", linewidth=1)
ax.set_xlabel("momentum $k_5$ along the extra time ($m = 1$, $k_1 = 0.5$)")
ax.set_ylabel("directions in the $+w$ eigenspace")
ax.set_yticks(range(0, 9))
ax.set_ylim(0.0, 10.5)  # room for the legend above the bars
```

```
ax.set_title("Krein inertia of one eigenspace across the threshold")
ax.legend(loc="upper center", ncol=3, fontsize=8)
save_figure(fig, "krein_inertia_scan",
...)
```

The dotted line marks the threshold; the vertical axis is labelled 0 to 8 and extended to 10.5 to leave room for the legend, which is written in three columns at the top. Figure 4 of Notebook 10a shows bars that are half blue and half orange left of the threshold and entirely green right of it: the waves of real frequency mix the two signs of charge four and four, the growing waves carry no charge.

In [15], the Gram matrices of three waves.

```
cases = [(2, {0: 4, 1: 1, 2: 2}, "$m = 2$, $k = (4, 1, 2, 0)$: $w = 5$"),
         (2, {5: 1}, "$m = 2$, $k_5 = 1$: $w = \\sqrt{3}$"),
         (1, {5: 2}, "$m = 1$, $k_5 = 2$: $w = i\\sqrt{3}$")]
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.2))
block_sizes = []
```

Three waves are compared: a good-sector wave with $w = 5$, a wave with extra-time momentum and a real frequency $w = \sqrt{4-1} = \sqrt{3}$, and a wave with an imaginary frequency $w = \sqrt{1-4} = i\sqrt{3}$. Each entry of `cases` holds the mass, the momenta and the title of its panel.

```
for ax, (m_value, k, title) in zip(axes, cases):
    W = np.hstack([eigenspace(m_value, k, +1), eigenspace(m_value, k, -1)])
    gram = np.abs(W.conj().T @ B @ W)  # sizes of the Krein form between columns
    image = draw_matrix(ax, gram, title, cmap=SEQUENTIAL, vmin=0.0, vmax=1.0)
    ax.axhline(7.5, color=GREY, linewidth=1)  # the border between the two
    ax.axvline(7.5, color=GREY, linewidth=1)  # eigenspaces (rows/columns 8 and 9)
```

`np.hstack` puts the 8 basis columns of the $+w$ eigenspace and the 8 of the $-w$ eigenspace side by side into one 16×16 matrix W. `gram` holds the sizes of the entries of $W^\dagger B W$, the Krein form between every pair of these columns, drawn with the white-to-blue scale; grey lines separate the two eigenspaces.

```
    diagonal_blocks = max(gram[:8, :8].max(), gram[8:, 8:].max())
    off_blocks = max(gram[:8, 8:].max(), gram[8:, :8].max())
    block_sizes.append((diagonal_blocks, off_blocks))
    say(f"case {len(block_sizes)}: largest entry in the diagonal blocks "
        f"{diagonal_blocks:.3f}; off-diagonal blocks below 1e-12: {off_blocks < 1e-12}")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="size of the entry")
save_figure(fig, "krein_gram_matrices",
...)
```

`gram[:8, :8]` is the upper left 8×8 block (rows and columns 1 to 8), `gram[8:, 8:]` the lower right one, and the two others are the off-diagonal blocks. The printed lines show, for the first two cases, diagonal blocks with entries up to 0.894 and 0.866 and empty off-diagonal blocks (`True`), and for the third case empty diagonal blocks (`0.000`) and filled off-diagonal blocks (`False`). Figure 5 of Notebook 10a shows exactly this: for a real frequency the two eigenspaces are Krein-orthogonal (step (i)); for an imaginary frequency each eigenspace is neutral, and a growing wave has a nonzero Krein form only with a decaying one.

```
check(block_sizes[0][1] < 1e-12 and block_sizes[1][1] < 1e-12
      and block_sizes[2][0] < 1e-12 and block_sizes[2][1] > 0.1,
      "real w: the eigenspaces are Krein-orthogonal; imaginary w: each is neutral")
```

The check states the same in numbers.

In [16], the universes of masses $+m$ and $-m$.

```
Gamma_exact = g[0] * g[1] * g[2] * g[3] * g[4] * g[5] * g[6] * g[7]
h_minus = mode_hamiltonian_exact(-m, k_sym)  # the same momenta, mass -m
k_reflected = dict(k_sym)
k_reflected[0] = -k_sym[0]  # R_0: k0 -> -k0
h_minus_reflected = mode_hamiltonian_exact(-m, k_reflected)
```

The exact chirality Γ is the product of the eight gammas in the author's order. `h_minus` is $h_{-m}(k)$; `dict(k_sym)` makes a copy of the dictionary of momenta, in which k_0 is replaced by $-k_0$, and `h_minus_reflected` is $h_{-m}(R_0 k)$.

```
chirality_ok = (Gamma_exact * h_sym * Gamma_exact - h_minus).applyfunc(
    sp.expand) == zero
mirror_ok = (g[0] * h_sym * g[0] - h_minus_reflected).applyfunc(sp.expand) == zero
check_record(Gamma_exact * Gamma_exact == I16 and chirality_ok,
             "exact: Gamma h_m(k) Gamma = h_-m(k)",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_maps")
check_record(mirror_ok, "exact: gamma^(x0) h_m(k) gamma^(x0) = h_-m(R_0 k)",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_one_particle_maps")
```

The two identities of Section 10.6 are checked exactly, for all m and k, with $\Gamma\Gamma = I_{16}$; they reproduce the sympy and the Wolfram record.

In [17], the B-sectors of the good sector and the two spectra.

```
h_sample = mode_hamiltonian(2, {0: 4, 1: 1, 2: 2})
P_B = (np.eye(16) + B) / 2  # projector onto the eigenvalue +1 of B
sector_values = np.round(np.linalg.eigvals(P_B @ h_sample @ P_B).real, 10)
multiplicities = {v: int(np.sum(sector_values == v)) for v in (5.0, -5.0, 0.0)}
say(f"eigenvalues of P_B h P_B and how often each occurs: {multiplicities}")
check_record(multiplicities == {5.0: 4, -5.0: 4, 0.0: 8},
             "good sector, m = 2, k = (4, 1, 2, 0): on B = +1 energies +5, -5 (4 each)",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_spectrum_and_B_sectors")
```

In the good sector B commutes with h, so the projector $P_B = \frac{1}{2}(I_{16} + B)$ onto the eight columns with $Bu = u$ commutes with h, and h acts inside that 8-dimensional space. The eigenvalues of $P_B h P_B$ are those of h on that space, together with 0 for the eight directions that P_B removes. `np.round(..., 10)` rounds them to 10 decimals so that equal values compare equal. The printed dictionary `{5.0: 4, -5.0: 4, 0.0: 8}` says: on the $B = +1$ sector the energies are $+5$ and -5, four of each, as step (ii) of Theorem 10.1 requires; this is the record's exact example.

```
k1_values = np.linspace(0.0, 4.0, 41)
plus_spectra = [np.sort(np.linalg.eigvals(mode_hamiltonian(2.0, {1: x})).real)
                for x in k1_values]
minus_spectra = [np.sort(np.linalg.eigvals(mode_hamiltonian(-2.0, {1: x})).real)
                 for x in k1_values]
mass_values = np.linspace(-3.0, 3.0, 61)
mass_spectra = [np.sort(np.linalg.eigvals(mode_hamiltonian(x, {1: 1.0})).real)
                for x in mass_values]
difference = np.max(np.abs(np.array(plus_spectra) - np.array(minus_spectra)))
report("largest difference between the spectra of m = 2 and m = -2", f"{difference:.1e}")
check(difference < 1e-10, "numerical: the spectra of h_m and h_-m coincide")
```

The sorted eigenvalues of h are computed for $m = +2$ and $m = -2$ at 41 values of k_1 from 0 to 4, and at $k_1 = 1$ for 61 masses from -3 to 3. The largest difference between the spectra of $+2$ and -2 is printed as `0.0e+00`: identical.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.0))
axes[0].plot(k1_values, np.array(plus_spectra)[:, [0, 15]], color=BLUE, linewidth=2)
axes[0].plot(k1_values, np.array(minus_spectra)[:, [0, 15]], "o", color=ORANGE,
             markersize=5, fillstyle="none")
axes[0].plot([], [], color=BLUE, linewidth=2, label="$m = +2$ (line)")
axes[0].plot([], [], "o", color=ORANGE, fillstyle="none", label="$m = -2$ (circles)")
```

`[:, [0, 15]]` picks the smallest and the largest eigenvalue, $-w$ and $+w$ (the other fourteen lie on top of these two). The spectra of $+2$ are drawn as lines, those of -2 as open circles (`fillstyle="none"`). The two calls with empty lists draw nothing; they only create the entries of the legend.

```
axes[0].set_xlabel("momentum $k_1$ (with $m = \\pm 2$)")
axes[0].set_ylabel("eigenvalues $\\pm w$ of $h$")
axes[0].set_title("same spectrum for $+m$ and $-m$")
axes[0].legend(loc="center left")
axes[1].plot(mass_values, np.array(mass_spectra)[:, [0, 15]], color=GREEN,
             linewidth=2)
axes[1].set_xlabel("mass $m$ (with $k_1 = 1$)")
axes[1].set_ylabel("eigenvalues $\\pm\\sqrt{m^2 + k_1^2}$ of $h$")
axes[1].set_title("the spectrum is even in $m$")
save_figure(fig, "plus_minus_mass_spectra",
...)
```

Figure 6 of Notebook 10a shows on the left the circles of $m = -2$ sitting exactly on the lines of $m = +2$, and on the right the eigenvalues $\pm\sqrt{m^2 + 1}$ against the mass: curves that are mirror images in the vertical axis $m = 0$. The one-particle spectra of the universes of masses $+m$ and $-m$ are identical, not opposite.

In [18], the last check.

```
for name in ("10a_1_gamma4_c_and_b.png", "10a_2_frequency_squared.png",
             "10a_3_eigenvalue_flow.png", "10a_4_krein_inertia_scan.png",
             "10a_5_krein_gram_matrices.png", "10a_6_plus_minus_mass_spectra.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The loop checks that each of the six figure files exists in the figure folder, and `all_checks_passed()` prints the last line, ALL 28 CHECKS PASSED (notebook 10a): the six figure checks of this cell and the 22 checks of the cells before.

10.11 Quantum states, operators and fermion modes from zero

Sections 10.2 to 10.6 treated one wave as a column u of 16 complex numbers. A quantum field is something else: its components become *operators* that act on *quantum states*. This section introduces the few notions that are needed, from zero, with small worked examples; Notebook 10b then builds all of them in Python.

States and the inner product. In the examples of this chapter a **quantum state** is a column $\psi = (\psi_1, \ldots, \psi_n)$ of n complex numbers. The **inner product** of two states ϕ and ψ is the complex number

$$\langle \phi | \psi \rangle = \sum_{j=1}^{n} \phi_j^* \psi_j .$$

For $\phi = \psi$ every term is $\psi_j^* \psi_j = |\psi_j|^2 \geq 0$, so $\langle \psi | \psi \rangle > 0$ for every state ψ that is not the zero column: the inner product is **positive**. The number $\|\psi\| = \sqrt{\langle \psi | \psi \rangle}$ is the **length** of ψ, and a state of length 1 is **normalised**. A space of states with a positive inner product is a **Hilbert space**. Positivity is what quantum mechanics needs for probabilities: for normalised ϕ and ψ the number $|\langle \phi | \psi \rangle|^2$ is the probability of finding ϕ in the state ψ, and a probability cannot be negative.

Operators and the Hilbert adjoint. An **operator** X maps every state to a state and respects sums and multiples, $X(a\phi + b\psi) = aX\phi + bX\psi$; here it is a matrix. The **Hilbert adjoint** of X is the operator X^* with

$$\langle \phi | X\psi \rangle = \langle X^* \phi | \psi \rangle \quad \text{for all states } \phi, \psi .$$

For the inner product above X^* is the conjugate transpose of the matrix X: $\langle \phi | X\psi \rangle = \phi^\dagger X \psi = (X^\dagger \phi)^\dagger \psi$. In this chapter the star on an operator always means the Hilbert adjoint, and the dagger on a field operator is kept for the *canonical conjugate* of Section 10.12; for numbers, matrices and columns the star and the dagger keep their meaning of Section 10.1 (complex conjugate, conjugate transpose). One consequence of the definition is used again and again. Put $\psi = X^* \phi$:

$$\langle \phi | X X^* \phi \rangle = \langle X^* \phi | X^* \phi \rangle = \|X^* \phi\|^2 \geq 0 .$$

The first step is the definition of X^* with $\psi = X^* \phi$; the second is the definition of the length. An operator with $X^* = X$ is **Hermitian**; its expectation values $\langle \phi | X \phi \rangle$ are real.

Commutator, anticommutator and the Heisenberg equation. For two operators, $[X, Y] = XY - YX$ is the **commutator** and $\{X, Y\} = XY + YX$ the **anticommutator**. We shall need the identity

$$[XY, Z] = X\{Y, Z\} - \{X, Z\}Y .$$

Proof: the right side is $X(YZ+ZY)-(XZ+ZX)Y = XYZ+XZY-XZY-ZXY = XYZ-ZXY$, by multiplying out and cancelling XZY, and $XYZ - ZXY$ is $[XY, Z]$ by the definition of the commutator. The energy operator H (the **Hamiltonian**) moves the system in time. In the Heisenberg picture the states stay fixed and an operator O changes with the time x_4 as $O(x_4) = e^{iHx_4} O e^{-iHx_4}$. Differentiating with the product rule, and using that H commutes with $e^{\pm iHx_4}$ (both are power series in H), gives the **Heisenberg equation**

$$\frac{dO}{dx_4} = iH\,O(x_4) - i\,O(x_4)H = i\,[H, O(x_4)].$$

One fermion mode and the Pauli principle. Let b be an operator with

$$\{b, b^*\} = 1, \qquad b\,b = 0.$$

Then also $b^*b^* = (bb)^* = 0$. The **number operator** $N = b^*b$ obeys

$$NN = b^*bb^*b = b^*(1 - b^*b)b = b^*b - b^*b^*bb = N.$$

The second step replaces bb^* by $1 - b^*b$ (the anticommutator); the third multiplies out; the fourth uses $b^*b^* = 0$. If $Nv = nv$ for a state $v \neq 0$, then $nv = Nv = NNv = n^2v$, so $n^2 = n$: $n = 0$ or $n = 1$. A fermion mode is either empty or occupied once. This is the **Pauli principle**, and it follows from the anticommutator alone. Example: on the two states $|0\rangle = (1, 0)$ (empty) and $|1\rangle = (0, 1)$ (occupied) the matrices

$$b = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \qquad b^* = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

give $bb^* = \mathrm{diag}(1, 0)$ and $b^*b = \mathrm{diag}(0, 1)$, whose sum is the identity; $b|1\rangle = |0\rangle$ (it **annihilates** the fermion), $b^*|0\rangle = |1\rangle$ (it **creates** one), and $b^*|1\rangle = 0$: a second fermion cannot be created.

Many modes, patterns and the sign. With n modes $f_0, \ldots, f_{n-1}$ the rules are

$$\{f_p, f_q^*\} = \delta_{pq}, \qquad \{f_p, f_q\} = 0,$$

where δ_{pq} is 1 for $p = q$ and 0 otherwise. A basis state is a **pattern** of occupations $(o_0, o_1, \ldots, o_{n-1})$, each o_p being 0 (empty) or 1 (occupied); there are 2^n patterns. The pattern with every mode empty is the **vacuum** $|0\rangle$. The **Fock space** is the set of all superpositions of patterns, with the positive inner product in which the patterns are orthonormal. The operators act on a pattern as follows:

- f_p: if mode p is occupied it empties it and multiplies by $(-1)^s$, where s is the number of occupied modes below p (the modes $0, \ldots, p-1$); if mode p is empty the result is 0;
- f_p^*: if mode p is empty it fills it and multiplies by the same $(-1)^s$; if it is occupied the result is 0.

Why the sign: take two modes and write a pattern as $|o_0 o_1\rangle$. Then $f_0|11\rangle = |01\rangle$ (no occupied mode below 0), and $f_1|01\rangle = |00\rangle$ (mode 0 is empty), so $f_1 f_0|11\rangle = |00\rangle$. In the other order $f_1|11\rangle = -|10\rangle$ (one occupied mode, mode 0, lies below mode 1), and $f_0|10\rangle = |00\rangle$, so $f_0 f_1|11\rangle = -|00\rangle$. The sum is $\{f_0, f_1\}|11\rangle = 0$, as the rules require; without the sign it would be $2|00\rangle$. The rule $\{f_p, f_p^*\} = 1$ holds on every pattern: if mode p is empty, f_p^* fills it with a sign $(-1)^s$, f_p empties it again with the same sign (the modes below p have not changed), and $f_p^* f_p$ gives 0; the sum is $(-1)^{2s} = 1$ times the pattern. If mode p is occupied, the roles of the two products are exchanged.

A pattern as one whole number. The notebooks store the pattern $(o_0, \ldots, o_{n-1})$ as the whole number $n_{\text{pattern}} = \sum_p o_p 2^p$, whose binary digit number p (counted from 0, the last digit first) is o_p. For example, with modes 0 and 3 occupied the number is $1 + 8 = 9$, binary 1001. The number of occupied modes below p is the number of digits 1 among the binary digits $0, \ldots, p-1$. A state is stored as a Python dictionary that pairs every pattern of nonzero amplitude with its amplitude; the vacuum is the dictionary with the pattern 0 and the amplitude 1. With 16 modes there are $2^{16} = 65536$ patterns, but a state is stored by the few patterns it contains.

10.12 The canonical rule from the Lagrangian

To **quantise** dirac16complex means to replace its 16 components Ψ_A by operators and to fix their anticommutators. *Canonical quantisation* reads the rule off the Lagrangian, with the time x_4 as the evolution time. The slices $x_4 =$ const are seven-dimensional, with the coordinates $x_1, x_2, x_3, x_5, x_6, x_7, x_0$.

The time-derivative term, line by line. In the author's metric the Lagrangian density of dirac16complex is (Chapter 7, record `Revision/theory/field-theory.json`)

$$\mathcal{L} = \cos z \left[\tfrac{1}{2} \sum_a f_a^{-1} \big(\bar{\Psi} \gamma^{(x_a)} \partial_a \Psi - \partial_a \bar{\Psi} \gamma^{(x_a)} \Psi \big) - mS - U(S) \right],$$

with $\sqrt{|g|} = \cos z$ (on the backgrounds $b_4 = 1$ of the record, on which this chapter works; $b_4^{3/2} \cos z$ for the general metric of Chapter 3), the scale factors f_a of Section 10.3 ($f_4 = 1$), $\bar{\Psi} = \Psi^\dagger C$ and $S = \bar{\Psi}\Psi$; in this metric the spin connection drops out of the Lagrangian (`wolfram-field-theory.json`, check `L_spin_connection_drops_out_G`). The only terms with a derivative in x_4 are those with $a = 4$:

$$\tfrac{1}{2} \cos z \, \big(\Psi^\dagger C \gamma^{(x_4)} \partial_4 \Psi - \partial_4 \Psi^\dagger C \gamma^{(x_4)} \Psi \big).$$

This line writes out $\bar{\Psi} = \Psi^\dagger C$. Now $C\gamma^{(x_4)} = iB$, because the definition $B = -iC\gamma^{(x_4)}$ multiplied by i gives $iB = C\gamma^{(x_4)}$. Insert it:

$$\tfrac{i}{2} \cos z \, \big(\Psi^\dagger B \, \partial_4 \Psi - \partial_4 \Psi^\dagger B \, \Psi \big).$$

Add the total derivative $\frac{i}{2} \partial_4 (\cos z \, \Psi^\dagger B \Psi)$. A total derivative does not change the field equations (its integral over the time depends only on the end values, which the variation keeps fixed; Chapter 7). Since $\cos z$ does not depend on x_4, the product rule gives $\frac{i}{2} \partial_4 (\cos z \, \Psi^\dagger B \Psi) = \frac{i}{2} \cos z \, (\partial_4 \Psi^\dagger B \Psi + \Psi^\dagger B \partial_4 \Psi)$. Added to the line above, the two terms with $\partial_4 \Psi^\dagger$ cancel and the two with $\partial_4 \Psi$ add:

$$i\cos z\,\Psi^\dagger B\,\partial_4\Psi = \Psi^\dagger K\,\partial_4\Psi, \qquad K = i\cos z\,B.$$

The rest of the Lagrangian has no x_4-derivative; the Revision record writes it as $-\mathcal{H}$ with the **Hamiltonian density** $\mathcal{H} = \cos z\,[\Psi^\dagger(mC - \sum_{\mu\neq x_4} C\gamma^\mu D_\mu)\Psi + U(S)]$, so that $\mathcal{L} = \Psi^\dagger K\partial_4\Psi - \mathcal{H}$ exactly, up to the total derivative (`python-field-theory.json`, check `hamiltonian_form_and_heisenberg_equation`). In words: the time-derivative term contains the matrix B, and the momentum conjugate to Ψ_A is $\pi_A = i\cos z\,(\Psi^\dagger B)_A$, which depends on $\Psi^\dagger$ only, as for Dirac's electron (`python-field-theory.json`, check `canonical_momentum`).

The rule, line by line. Take a Lagrangian of the form $\Psi^\dagger K\partial_4\Psi - \Psi^\dagger h'\Psi$ with constant matrices K and h' (one point of the slice; the derivatives along the slice are inside h'). Varying $\Psi^\dagger$ gives the classical equation

$$K\,\partial_4\Psi = h'\Psi, \qquad \text{that is} \qquad \partial_4\Psi = K^{-1}h'\Psi.$$

In the quantum theory suppose that the operators obey $\{\Psi_A, \Psi_C^\dagger\} = A_{AC}$ with an unknown matrix A, and $\{\Psi_A, \Psi_C\} = 0$. The energy operator is $H = \Psi^\dagger h'\Psi = \sum_{A,C}\Psi_A^\dagger h'_{AC}\Psi_C$. For one component Ψ_c:

$$[H,\Psi_c] = \sum_{A,C} h'_{AC}\,[\Psi_A^\dagger\Psi_C, \Psi_c] = \sum_{A,C} h'_{AC}\big(\Psi_A^\dagger\{\Psi_C,\Psi_c\} - \{\Psi_A^\dagger,\Psi_c\}\Psi_C\big).$$

The first step takes the numbers h'_{AC} out of the commutator; the second is the identity $[XY,Z] = X\{Y,Z\} - \{X,Z\}Y$ of Section 10.11 with $X = \Psi_A^\dagger$, $Y = \Psi_C$, $Z = \Psi_c$. Now $\{\Psi_C,\Psi_c\} = 0$ and $\{\Psi_A^\dagger,\Psi_c\} = \{\Psi_c,\Psi_A^\dagger\} = A_{cA}$, so

$$[H,\Psi_c] = -\sum_{A,C} A_{cA}h'_{AC}\Psi_C = -(Ah'\Psi)_c,$$

by the definition of a matrix product. The Heisenberg equation then reads

$$\partial_4\Psi = i[H,\Psi] = -iAh'\Psi.$$

It agrees with the classical equation $\partial_4\Psi = K^{-1}h'\Psi$ for every h' exactly when $-iA = K^{-1}$, that is $A = iK^{-1}$. With $K = i\cos z\,B$, $B^{-1} = B$ (Section 10.2) and $1/i = -i$:

$$iK^{-1} = i\cdot\frac{1}{i\cos z}\,B^{-1} = \frac{B}{\cos z}.$$

From one point to the whole slice. So far the slice was a single point. To pass to the whole slice, divide it into many small cells, each with the coordinate volume ΔV (the product of its seven coordinate widths), and keep one value $\Psi(x)$ of the field per cell x. The Lagrangian of the slice is then the sum over the cells of ΔV times the density, so the time-derivative term of the cell x is $\Psi(x)^\dagger(K\Delta V)\,\partial_4\Psi(x)$, with $K = i\cos z\,B$ at the position of that cell; this term couples no two different cells (the derivatives along the slice, which do couple neighbouring cells, sit in h'). The rule just derived holds for any number of components: take as the components all 16 components of

all cells. Their time-derivative kernel is block diagonal, with one block $K\Delta V$ per cell, so its inverse is block diagonal with the blocks $(K\Delta V)^{-1}$, and the rule $A = iK^{-1}$ gives

$$\{\Psi_A(x), \Psi_C^\dagger(y)\} = i\,(K\Delta V)^{-1}_{AC}\,\delta_{xy} = B_{AC}\,\frac{\delta_{xy}}{\cos z\,\Delta V},$$

where δ_{xy} is 1 for the same cell and 0 for two different cells: components of different cells anticommute. The second step is $iK^{-1} = B/\cos z$ from above, divided by ΔV. As the cells shrink, $\delta_{xy}/\Delta V$ becomes the seven-dimensional **delta function** $\delta^7(x-y)$. It is defined by what it does in an integral: it is zero for $x \neq y$, and for every smooth function f on the slice

$$\int f(y)\,\delta^7(x-y)\,d^7y = f(x),$$

just as the sum over the cells $\sum_y \Delta V\, f(y)\,\delta_{xy}/\Delta V = f(x)$ picks out the cell x. It is not an ordinary function (no ordinary function is zero everywhere but at one point and still has the integral 1) but a rule for integrals, and in the theory it only appears inside such integrals. So the **canonical anticommutator** of dirac16complex on a slice $x_4 = \text{const}$ is

$$\{\Psi_A(x), \Psi_C^\dagger(y)\} = B_{AC}\,\frac{\delta^7(x-y)}{\cos z}.$$

At one point the factor $1/\cos z$ is a positive number, which changes no sign; the notebooks therefore work with $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$.

The Heisenberg equation is the wave equation. For a plane wave with frame momenta k_a along the slice, at one point with frozen coefficients, the derivatives D_a in $\mathcal{H}$ become ik_a and

$$h' = mC - i\sum_{a\neq 4} k_a\, C\gamma^{(x_a)}.$$

Multiply by $B = -iC\gamma^{(x_4)}$:

$$Bh' = -im\,C\gamma^{(x_4)}C - \sum_{a\neq 4} k_a\, C\gamma^{(x_4)}C\gamma^{(x_a)} = -im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_{a\neq 4} k_a\gamma^{(x_a)} = h.$$

The first step multiplies out $((-i)(-i) = -1)$; the second moves C through $\gamma^{(x_4)}$ (they commute, (B1) of Section 10.2) and uses $CC = I_{16}$; the result is the mode Hamiltonian h of Section 10.3. With $A = B$ the Heisenberg equation is $\partial_4\Psi = -iBh'\Psi = -ih\Psi$, that is $i\,\partial_4\Psi = h\Psi$: the quantum field obeys the classical wave equation of the field.

Why anticommutators. The rule uses anticommutators because dirac16complex is a fermion field by the author's definition: its components are anticommuting numbers. In ordinary 3+1 dimensional physics this choice is not free: the **spin-statistics theorem** of quantum field theory shows that, if the energy is to be bounded below and measurements at two points that no signal can connect are not to disturb each other, fields of half-integer spin (such as the electron's) must be quantised with anticommutators and fields of whole-number spin with commutators. No such theorem is proved for signature (4,4); here the anticommutator is an ASSUMPTION, part of the definition of the field.

10.13 The canonical conjugate is not the Hilbert adjoint: the Krein space

In ordinary quantum theory the canonical conjugate $\Psi^\dagger$ is the Hilbert adjoint of Ψ. In signature (4,4) this is impossible.

Theorem 10.2 (the canonical rule forces a Krein space). There is no space of states with a positive inner product on which operators Ψ_A obey $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$ with $\Psi^\dagger_A$ the Hilbert adjoint of Ψ_A. (PROVED: `python-field-theory.json` and `wolfram-field-theory.json`, check `no_positive_inner_product`.)

Proof. Take the column u with $u_7 = -i/\sqrt{2}$, $u_{16} = 1/\sqrt{2}$ and all other entries 0 (the column named by the record). By the table of B in Section 10.2, $(Bu)_7 = B_{7,16}u_{16} = i/\sqrt{2} = -u_7$ and $(Bu)_{16} = B_{16,7}u_7 = (-i)(-i/\sqrt{2}) = -1/\sqrt{2} = -u_{16}$, so $Bu = -u$; and $u^\dagger u = \frac{1}{2} + \frac{1}{2} = 1$, so $u^\dagger B u = -u^\dagger u = -1$. Define the operator $X = \sum_A u^*_A \Psi_A$ and its canonical conjugate $X^\dagger = \sum_A u_A \Psi^\dagger_A$. Then

$$\{X, X^\dagger\} = \sum_{A,C} u^*_A u_C \{\Psi_A, \Psi^\dagger_C\} = \sum_{A,C} u^*_A B_{AC} u_C = u^\dagger B u = -1.$$

The first step takes the numbers out of the anticommutator; the second is the canonical rule; the third is the definition of $u^\dagger B u$. Suppose now that $X^\dagger$ were the Hilbert adjoint X^*. Then for every normalised state ϕ, by the consequence of the definition of the adjoint in Section 10.11,

$$\langle\phi|\{X,X^*\}\phi\rangle = \langle\phi|XX^*\phi\rangle + \langle\phi|X^*X\phi\rangle = \|X^*\phi\|^2 + \|X\phi\|^2 \geq 0,$$

while $\{X,X^*\} = -1$ gives $\langle\phi|(-1)\phi\rangle = -1$. A number cannot be both ≥ 0 and -1. QED.

What remains: a Krein space. The canonical rule itself is consistent; what fails is only its reading with a positive inner product. A **Krein space** is a space with a Hermitian form $[u,v]$ that is *nondegenerate* (no nonzero u has $[u,v]=0$ for all v) but *indefinite* (it takes both signs), together with a matrix J, the **fundamental symmetry**, with $J^\dagger = J = J^{-1}$, such that $[u,Jv]$ is a positive inner product. For the one-particle columns of dirac16complex, $[u,v] = u^\dagger Bv$ and $J = B$: indeed $[u,Bv] = u^\dagger BBv = u^\dagger v$, the ordinary positive inner product. The theorem says that the canonical rule turns the state space of the field into a Krein space with fundamental symmetry B, whenever $\Psi^\dagger$ is read as the adjoint.

10.14 Two realisations and the expectation-value rule

The Revision record describes two honest ways to realise the canonical rule on a concrete space of states.

(a) The positive realisation. Keep a POSITIVE Fock space, with 16 modes $f_0,\ldots,f_{15}$, and let $\Psi_A = f_{A-1}$ and $\chi_A = f^*_{A-1}$, the Hilbert adjoint. Then *define* the canonical conjugate as

$$\Psi^\dagger_A = \sum_C \chi_C B_{CA}, \qquad \text{briefly} \qquad \Psi^\dagger = \chi B.$$

Line by line,

$$\{\Psi_A, \Psi^\dagger_C\} = \sum_D \{\Psi_A,\chi_D\}B_{DC} = \sum_D \delta_{AD}B_{DC} = B_{AC}.$$

The first step takes the numbers B_{DC} out of the anticommutator; the second is the Fock rule $\{f_{A-1}, f^*_{D-1}\} = \delta_{AD}$; the third keeps the one term $D = A$. So the canonical rule holds on a positive space, but $\Psi^\dagger$ is not the Hilbert adjoint: for the column u of Theorem 10.2,

$$X^\dagger = \sum_A u_A \Psi^\dagger_A = \sum_{A,C} u_A\chi_C B_{CA} = \sum_C (Bu)_C\chi_C = -\sum_C u_C\chi_C = -X^*,$$

where the third step collects $\sum_A B_{CA}u_A = (Bu)_C$, the fourth uses $Bu = -u$, and the last recognises $X^* = \sum_C u_C\chi_C$, the Hilbert adjoint of $X = \sum_C u^*_C\Psi_C$. So $\{X,X^*\} = +1$ (positive, as in every Hilbert space) while $\{X,X^\dagger\} = -1$ (the canonical value): the two differ by a sign. This is the form the Revision record uses for the good sector (Section 10.20).

(b) The Krein-Fock realisation. Keep $\Psi^\dagger$ as the conjugate and let the modes carry Krein norms ± 1. Choose 16 columns $u_1,\ldots,u_{16}$ with $u^\dagger_n Bu_{n'} = \epsilon_n\delta_{nn'}$, $\epsilon_n = +1$ or -1 (*Krein-orthonormal* modes). Write U for the matrix with these columns and $E = \mathrm{diag}(\epsilon_1,\ldots,\epsilon_{16})$, so that $U^\dagger BU = E$. Then also $UEU^\dagger = B$: multiply $U^\dagger BU = E$ from the left by UE, which gives $UEU^\dagger BU = UEE = U$ (because $EE = I_{16}$); multiply from the right by U^{-1}: $UEU^\dagger B = I_{16}$; multiply from the right by B:

$UEU^\dagger = B$ (because $BB = I_{16}$). Take operators b_n with $\{b_n, b^\dagger_{n'}\} = \epsilon_n \delta_{nn'}$ and put $\Psi = \sum_n u_n b_n$, $\Psi^\dagger = \sum_n u^\dagger_n b^\dagger_n$. Then

$$\{\Psi_A, \Psi^\dagger_C\} = \sum_{n,n'} (u_n)_A (u_{n'})^*_C \{b_n, b^\dagger_{n'}\} = \sum_n \epsilon_n (u_n)_A (u_n)^*_C = (UEU^\dagger)_{AC} = B_{AC} :$$

the same canonical rule. The simplest choice takes 8 eigenvectors of B with eigenvalue $+1$ ($\epsilon = +1$) and 8 with eigenvalue -1 ($\epsilon = -1$). A **Krein boost** of a pair, $u'_1 = \cosh t\, u_1 + \sinh t\, u_9$ and $u'_9 = \sinh t\, u_1 + \cosh t\, u_9$ (with $Bu_1 = u_1$, $Bu_9 = -u_9$, both of length 1 and orthogonal), keeps the Krein norms, because $\cosh^2 t - \sinh^2 t = 1$, and keeps the two modes Krein-orthogonal, because $\cosh t \sinh t - \sinh t \cosh t = 0$; but it changes the ordinary squared length to $\cosh^2 t + \sinh^2 t$. The record uses $\cosh t = \frac{5}{4}$, $\sinh t = \frac{3}{4}$ ($\frac{25}{16} - \frac{9}{16} = 1$), so the boosted mode has the ordinary squared length $\frac{25}{16} + \frac{9}{16} = \frac{34}{16} = 2.125$.

The expectation-value rule, line by line. In the one-mode state $b^\dagger_n|0\rangle$ (with $b_{n'}|0\rangle = 0$ for all n') the observable $\Psi^\dagger M \Psi = \sum_{k,k'} (u^\dagger_k M u_{k'})\, b^\dagger_k b_{k'}$ has the vacuum value

$$\langle 0|b_n (\Psi^\dagger M \Psi) b^\dagger_n|0\rangle = \sum_{k,k'} (u^\dagger_k M u_{k'}) \langle 0|b_n b^\dagger_k b_{k'} b^\dagger_n|0\rangle = \sum_{k,k'} (u^\dagger_k M u_{k'})\, \epsilon_n \delta_{k'n}\, \epsilon_n \delta_{kn} = u^\dagger_n M u_n .$$

The first step inserts the expansion; the second uses $b_{k'} b^\dagger_n|0\rangle = \{b_{k'}, b^\dagger_n\}|0\rangle = \epsilon_n \delta_{k'n}|0\rangle$ (the term $b^\dagger_n b_{k'}|0\rangle$ vanishes) and in the same way $\langle 0|b_n b^\dagger_k|0\rangle = \epsilon_n \delta_{kn}$; the third uses $\epsilon_n^2 = 1$. The Krein norm of the state is $\langle 0|b_n b^\dagger_n|0\rangle = \epsilon_n$, so the **normalised** expectation value is

$$\frac{\langle 0|b_n (\Psi^\dagger M \Psi) b^\dagger_n|0\rangle}{\langle 0|b_n b^\dagger_n|0\rangle} = \epsilon_n\, u^\dagger_n M u_n .$$

For a mode that is an eigenvector of B, $Bu_n = \epsilon_n u_n$, the conjugate transpose gives $u^\dagger_n B = \epsilon_n u^\dagger_n$ (B is Hermitian and ϵ_n real), so $\epsilon_n u^\dagger_n M u_n = u^\dagger_n B M u_n$, the form in which the Revision specification states the rule. For a Krein-boosted mode $Bu_n \neq \epsilon_n u_n$, and the form $u^\dagger_n B M u_n$ is wrong; the general rule is $\epsilon_n u^\dagger_n M u_n$ (`python-field-theory.json`, check `expectation_value_rule`).

10.15 Maps that keep the canonical rule, and the conjugation of the quantised field

Linear maps. If $\Psi' = M\Psi$ with a constant matrix M, the conjugate is $\Psi'^\dagger = \Psi^\dagger M^\dagger$, that is $\Psi'^\dagger_C = \sum_F \Psi^\dagger_F M^*_{CF}$, and

$$\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{D,F} M_{AD} M^*_{CF} \{\Psi_D, \Psi^\dagger_F\} = \sum_{D,F} M_{AD} B_{DF} M^*_{CF} = (MBM^\dagger)_{AC} .$$

The map keeps the canonical rule exactly when $MBM^\dagger = B$. The Revision pairing record lists $MBM^\dagger = \sigma B$ with a sign σ for 17 maps (`Revision/pairing/pairing-theory.json`, data `Krein_signs_M_B_Mdagger`; `wolfram-pairing.json`, check `Q_Krein_metric_of_images`). The signs follow from Section 10.2 in three lines. For a gamma, $(\gamma^{(x_a)})^\dagger = (\gamma^{(x_a)})^T = \eta_{aa} \gamma^{(x_a)}$ (the

gammas are real; the space-like ones are symmetric, the time-like ones antisymmetric) and $\gamma^{(x_a)}B = s_a B\gamma^{(x_a)}$ with $s_a = +1$ for $a = 1,2,3,4,8$ and $s_a = -1$ for $a = 5,6,7$; so

$$\gamma^{(x_a)}B(\gamma^{(x_a)})^\dagger = \eta_{aa}\,\gamma^{(x_a)}B\gamma^{(x_a)} = \eta_{aa}s_a\,B\gamma^{(x_a)}\gamma^{(x_a)} = \eta_{aa}s_a\eta_{aa}\,B = s_aB.$$

For the chirality, Γ is real and symmetric and $\Gamma B\Gamma = -B$ (Section 10.2), so $\Gamma B\Gamma^\dagger = -B$. For the reflection $P_a = \Gamma\gamma^{(x_a)}$ the two signs multiply: $\sigma = -s_a$. The table:

map M	**sign** σ **in** $MBM^\dagger = \sigma B$
Γ	-1
$\gamma^{(x_1)}, \gamma^{(x_2)}, \gamma^{(x_3)}, \gamma^{(x_4)}, \gamma^{(x_0)}$	$+1$
$\gamma^{(x_5)}, \gamma^{(x_6)}, \gamma^{(x_7)}$	-1
P_1, P_2, P_3, P_4, P_0	-1
P_5, P_6, P_7	$+1$

The chirality image $\Gamma\Psi$ of the pairing theorem T1 therefore carries the Krein metric $-B$ (statement Q1 of the quantum reading of the pairing record, Section 10.44), while the mirror image $\gamma^{(x_0)}\Psi$ of theorem T2 keeps $+B$ (statement Q5).

The conjugation of the quantised field. Charge conjugation is a MATRIX map (Chapter 5): the two charge-conjugation matrices are $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$, and for a classical field they give $\Psi^c = \mathcal{C}_+\bar\Psi^T = CC\Psi^* = \Psi^*$ (same mass) and $\Psi^c = \mathcal{C}_-\bar\Psi^T = \Gamma\Psi^*$ (mass reversed), since $\bar\Psi^T = (\Psi^\dagger C)^T = C^T\Psi^* = C\Psi^*$. (For a REAL field $\Psi^* = \Psi$, so the first map is the identity: a real field is its own conjugate, and plain complex conjugation does nothing to it; the nontrivial real map is Γ, Chapter 5.) For the QUANTISED field the role of Ψ^* is played by the column of conjugate operators $\Psi^{\dagger T}$, and the candidate conjugations are $\Psi^c = M\Psi^{\dagger T}$, that is $\Psi^c_A = \sum_D M_{AD}\Psi^\dagger_D$. Its conjugate is $\Psi^{c\dagger}_C = \sum_F M^*_{CF}\Psi_F$ (the conjugate of $\Psi^\dagger$ is Ψ). Line by line,

$$\{\Psi^c_A, \Psi^{c\dagger}_C\} = \sum_{D,F} M_{AD}M^*_{CF}\{\Psi^\dagger_D, \Psi_F\} = \sum_{D,F} M_{AD}B_{FD}M^*_{CF} = (MB^TM^\dagger)_{AC}.$$

The second step uses $\{\Psi^\dagger_D, \Psi_F\} = \{\Psi_F, \Psi^\dagger_D\} = B_{FD}$, and the third $B_{FD} = (B^T)_{DF}$. Because B is Hermitian and purely imaginary, $B^T = (B^\dagger)^* = B^* = -B$. Hence:

- $M = I_{16}$ (the $\mathcal{C}_+$ type, $\Psi \to \Psi^{\dagger T}$): $MB^TM^\dagger = -B$, the sign of the canonical rule is REVERSED;
- $M = \Gamma$ (the $\mathcal{C}_-$ type, $\Psi \to \Gamma\Psi^{\dagger T}$): $\Gamma B^T\Gamma^\dagger = -\Gamma B\Gamma = +B$, the canonical rule is KEPT.

So the conjugation of the quantised field that preserves $\{\Psi, \Psi^\dagger\} = B\delta$ is $\Psi \to \Gamma\Psi^{\dagger T}$, and it reverses the mass: the gammas are real, so the conjugate of the field equation $\gamma^\mu\partial_\mu\Psi = m\Psi$ (flat space, $U = 0$) is $\gamma^\mu\partial_\mu\Psi^* = m\Psi^*$, and since Γ anticommutes with every gamma, $\gamma^\mu\partial_\mu(\Gamma\Psi^*) = -\Gamma\gamma^\mu\partial_\mu\Psi^* = -m\,\Gamma\Psi^*$: the conjugated field obeys the equation of mass $-m$ (`charge-conjugation-and-u1.json`, check `quantum_charge_conjugation_unitary_type`). Chapter 21 uses this result for matter and antimatter.

10.16 Example: Notebook 10b builds the canonical rule on a Fock space

Notebook 10b repeats the derivation of $iK^{-1} = B/\cos z$ exactly with sympy, builds the fermionic Fock space of Section 10.11 in a few lines of Python, realises on it the canonical rule $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$ with $\Psi^\dagger = \chi B$ (Section 10.14), checks that the Heisenberg equation gives the classical wave equation (Section 10.12), checks Theorem 10.2 on the recorded column and makes the positivity visible for 300 random states, builds the Krein-Fock realisation with a Krein-boosted pair and checks the expectation-value rule for 60 random matrices, and reproduces the 17 signs of Section 10.15 and the conjugation $\Psi \to \Gamma \Psi^{\dagger T}$. It draws five figures and ends with the line ALL 25 CHECKS PASSED (notebook 10b).

10.17 How to run Notebook 10b

Step 1. What this notebook does and what it needs.

Notebook 10b (The canonical anticommutator forces a Krein space) is the file `Revision/textbook/notebooks/10b_canonical_krein.ipynb` of the repository Dirac_claude. It derives the canonical anticommutator of dirac16complex from the time derivative term of the Lagrangian (exactly, with sympy), builds a fermionic Fock space of the 16 components in a few lines of Python and checks on it the anticommutator, the Heisenberg equation and the theorem that the canonical conjugate cannot be the Hilbert adjoint in a space with a positive inner product; it then builds the Krein-Fock realisation with modes of negative Krein norm, including a Krein-boosted pair, checks

the expectation-value rule, and computes which matrix maps keep the anticommutator: the Krein signs of the chirality, of the eight gammas and of the eight reflections, and the conjugation of the quantised field that preserves the anticommutator (the matrix Gamma, which reverses the mass); five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10b_canonical_krein.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10b_canonical_krein.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10b_canonical_krein.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10b.captions.json`
- `Revision/textbook/figures/10b_1_positivity.png`
- `Revision/textbook/figures/10b_2_krein_norms_random.png`
- `Revision/textbook/figures/10b_3_krein_plane.png`
- `Revision/textbook/figures/10b_4_expectation_rule.png`
- `Revision/textbook/figures/10b_5_krein_signs.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10b_5_krein_signs.png exists
ALL 25 CHECKS PASSED (notebook 10b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10b_canonical_krein.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10b_canonical_krein.ipynb
python -m nbconvert --execute --inplace 10b_canonical_krein.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.18 Notebook 10b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10b_canonical_krein.ipynb`: every cell in order, with the output that the stored, executed notebook

holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

To *quantise* the field dirac16complex means to turn its 16 components $\Psi_A$
($A = 1, \dots, 16$) into operators on a space of states, with a rule for the
anticommutator $\{\Psi_A, \Psi^\dagger_C\} = \Psi_A\Psi^\dagger_C +
\Psi^\dagger_C\Psi_A$. This notebook

- derives that rule from the Lagrangian of the field (canonical quantisation with
  the time $x_4$): $\{\Psi_A(x), \Psi^\dagger_C(y)\} = B_{AC}\,\delta^7(x - y)/\cos z$
  with the matrix $B = -iC\gamma^{(x_4)}$;
- builds a *fermionic Fock space* (the quantum states of 16 fermion modes) in a few
  lines of Python, and checks on it the anticommutator and that the quantum
  equation of motion (the Heisenberg equation) gives back the classical wave
  equation of the field;
- checks the theorem that $\Psi^\dagger$ cannot be the ordinary (Hilbert) adjoint of
  $\Psi$ in a space whose inner product is positive: the state space must carry an
  indefinite inner product, a *Krein space*;
- builds the Krein-Fock realisation, with modes of negative Krein norm and a
  Krein-boosted pair, and checks the expectation-value rule of the Revision record;
- computes which matrix maps $\Psi \to M\Psi$ keep the anticommutator, and which
  conjugation of the quantised field keeps it: $\Psi \to \Gamma\Psi^{\dagger T}$
  with the chirality matrix $\Gamma$ (it reverses the mass); the map with $M = 1$
  would turn $B$ into $-B$;
- reproduces the corresponding checks of the Revision record and draws five
  teaching figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 10b (The canonical anticommutator forces a Krein space) is the file
‘Revision/textbook/notebooks/10b_canonical_krein.ipynb‘ of the repository Dirac_claude.
It derives the canonical anticommutator of dirac16complex from the time derivative term
of the Lagrangian (exactly, with sympy), builds a fermionic Fock space of the 16
components in a few lines of Python and checks on it the anticommutator, the Heisenberg
equation and the theorem that the canonical conjugate cannot be the Hilbert adjoint in a
space with a positive inner product; it then builds the Krein-Fock realisation with modes
of negative Krein norm, including a Krein-boosted pair, checks the expectation-value
rule, and computes which matrix maps keep the anticommutator: the Krein signs of the
chirality, of the eight gammas and of the eight reflections, and the conjugation of the
quantised field that preserves the anticommutator (the matrix Gamma, which reverses the
mass); five teaching figures. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
```

notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10b_canonical_krein.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10b_canonical_krein.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10b_canonical_krein.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10b.captions.json‘
- ‘Revision/textbook/figures/10b_1_positivity.png‘
- ‘Revision/textbook/figures/10b_2_krein_norms_random.png‘
- ‘Revision/textbook/figures/10b_3_krein_plane.png‘
- ‘Revision/textbook/figures/10b_4_expectation_rule.png‘
- ‘Revision/textbook/figures/10b_5_krein_signs.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10b_5_krein_signs.png exists
ALL 25 CHECKS PASSED (notebook 10b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10b_canonical_krein.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs).

Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 10b_canonical_krein.ipynb
python -m nbconvert --execute --inplace 10b_canonical_krein.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 10b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10b (The canonical anticommutator forces a Krein space) is the file
# Revision/textbook/notebooks/10b_canonical_krein.ipynb of the repository Dirac_claude.
# It derives the canonical anticommutator of dirac16complex from the time derivative term
# of the Lagrangian (exactly, with sympy), builds a fermionic Fock space of the 16

#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
```

```
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
```

```
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10b_canonical_krein.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10b_canonical_krein.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10b_canonical_krein.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10b.captions.json
# - Revision/textbook/figures/10b_1_positivity.png
# - Revision/textbook/figures/10b_2_krein_norms_random.png
# - Revision/textbook/figures/10b_3_krein_plane.png
# - Revision/textbook/figures/10b_4_expectation_rule.png
# - Revision/textbook/figures/10b_5_krein_signs.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
```

```
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10b_5_krein_signs.png exists
#     ALL 25 CHECKS PASSED (notebook 10b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10b_canonical_krein.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10b_canonical_krein.ipynb
#     python -m nbconvert --execute --inplace 10b_canonical_krein.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
```

```
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
#

## 3. The words used in this notebook

- **State, inner product, Hilbert space**: a quantum state is a vector; the inner
  product $\langle\phi|\psi\rangle = \sum_n \phi_n^*\psi_n$ of two states is a
  complex number, and $\langle\psi|\psi\rangle > 0$ for every state $\psi \neq 0$
  (it is *positive*). A space of states with a positive inner product is a
  *Hilbert space*. Positivity is what makes probabilities possible.
- **Operator, Hilbert adjoint**: an operator maps states to states. The Hilbert
  adjoint $X^*$ of $X$ is the operator with $\langle\phi|X\psi\rangle =
  \langle X^*\phi|\psi\rangle$ for all states; for a matrix it is the conjugate
  transpose.
- **Anticommutator**: $\{X, Y\} = XY + YX$.
- **Fermion mode, occupation, vacuum**: a fermion mode is either empty or occupied
  once (the Pauli principle). With 16 modes a basis state is a *pattern* of 16
  occupations (0 or 1); there are $2^{16} = 65536$ patterns. The *vacuum* is the
  pattern with every mode empty. The annihilation operator $f_p$ empties mode $p$
  and the creation operator $f_p^*$ fills it, with a sign explained in Section 6.
- **Fock space**: all superpositions of the patterns, with the positive inner
  product in which the patterns are orthonormal.
- **Canonical conjugate**: the operator $\Psi^\dagger_A$ that the Lagrangian pairs
  with $\Psi_A$; the question of the notebook is whether it equals the Hilbert
  adjoint $\Psi_A^*$.
- **Krein form, Krein space, fundamental symmetry**: a Krein space is a space with an
  indefinite but nondegenerate Hermitian form, here $[u, v] = u^\dagger B v$, and a
```

```
  matrix $J$ (here $J = B$) with $J^\dagger = J = J^{-1}$ such that
  $[u, Jv] = u^\dagger v$ is positive. $J$ is the *fundamental symmetry*.
- **Krein-orthonormal modes**: columns $u_n$ with $u_n^\dagger B u_m = \epsilon_n
  \delta_{nm}$, $\epsilon_n = +1$ or $-1$. A *Krein boost* mixes a mode of Krein
  norm $+1$ with one of $-1$ by the numbers $\cosh t$ and $\sinh t$; it keeps the
  Krein form but changes the ordinary length.
- **Pattern as a whole number**: the program stores a pattern as one whole number
  $n$ whose binary digit number $p$ (counted from 0) is the occupation of mode $p$;
  `n >> p & 1` reads that digit.
```

Text cell:

```
## 4. The physical and mathematical situation

**The time-derivative term of the Lagrangian, line by line.** The Lagrangian of
dirac16complex in the author's metric (the Revision theory record) is
$\mathcal{L} = \cos z\,\big[\frac12\sum_a f_a^{-1}(\bar\Psi\gamma^{(x_a)}\partial_a
\Psi - \partial_a\bar\Psi\gamma^{(x_a)}\Psi) - mS - U(S)\big]$ with $z = 6Hx_0$,
$\bar\Psi = \Psi^\dagger C$ and $f_4 = 1$. Its only terms with a derivative in the
time $x_4$ are

$$\tfrac12\cos z\,\big(\Psi^\dagger C\gamma^{(x_4)}\partial_4\Psi -
\partial_4\Psi^\dagger C\gamma^{(x_4)}\Psi\big).$$

The notebook checks that $C\gamma^{(x_4)} = iB$ (this is the definition
$B = -iC\gamma^{(x_4)}$ multiplied by $i$). Insert it:

$$\tfrac{i}{2}\cos z\,\big(\Psi^\dagger B\,\partial_4\Psi - \partial_4\Psi^\dagger
B\,\Psi\big).$$

Add the total derivative $\frac{i}{2}\partial_4(\cos z\,\Psi^\dagger B\Psi)$, which
does not change the field equations; since $\cos z$ does not depend on $x_4$, the
product rule gives $\frac{i}{2}\cos z(\partial_4\Psi^\dagger B\Psi +
\Psi^\dagger B\partial_4\Psi)$, and the sum is

$$i\cos z\,\Psi^\dagger B\,\partial_4\Psi = \Psi^\dagger K\,\partial_4\Psi,\qquad
K = i\cos z\,B .$$

**The rule.** For a Lagrangian of the first-order form $\Psi^\dagger K\partial_4\Psi
- \Psi^\dagger h'\Psi$ the classical equation is $K\partial_4\Psi = h'\Psi$. If the
quantum operators obey $\{\Psi_A, \Psi^\dagger_C\} = A_{AC}$ (and $\{\Psi_A,
\Psi_C\} = 0$), the operator $H = \Psi^\dagger h'\Psi$ satisfies
$[H, \Psi_c] = -(Ah'\Psi)_c$, so the Heisenberg equation $\partial_4\Psi =
i[H, \Psi]$ reads $\partial_4\Psi = -iAh'\Psi$. Agreement with the classical
equation $\partial_4\Psi = K^{-1}h'\Psi$ for every $h'$ requires $-iA = K^{-1}$,
that is $A = iK^{-1}$. With $K = i\cos z\,B$ and $B^{-1} = B$:

$$iK^{-1} = i\cdot\frac{1}{i\cos z}B^{-1} = \frac{B}{\cos z},\qquad
\{\Psi_A(x), \Psi^\dagger_C(y)\} = B_{AC}\,\frac{\delta^7(x - y)}{\cos z}.$$

(On a slice $x_4 = $ const the components at different points anticommute; the
seven-dimensional delta $\delta^7(x - y)$ expresses this. In the Fock-space
computations of this notebook one point is kept, so the anticommutator is the
```

```
matrix $B$ itself, up to the positive factor $1/\cos z$ that does not change any
sign.)

**The obstruction.** $B$ has the eigenvalue $-1$. For a column $u$ with $Bu = -u$
and $u^\dagger u = 1$, the operator $X = \sum_A u_A^*\Psi_A$ would have
$\{X, X^\dagger\} = u^\dagger Bu = -1$. If $X^\dagger$ were the Hilbert adjoint,
then for every state $\phi$ we would have $\langle\phi|\{X, X^\dagger\}|\phi\rangle =
\lVert X^\dagger\phi\rVert^2 + \lVert X\phi\rVert^2 \geq 0$, a contradiction. So the
canonical conjugate is not the Hilbert adjoint: the honest statement is that the
canonical rule defines a Krein space.
```

Text cell:

```
## 5. The time-derivative kernel and the canonical rule, exactly

The next cell reads the gammas, builds $C$, $B$ and the chirality $\Gamma =
\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ with numpy (whole numbers and the
imaginary unit `1j`), and checks $C\gamma^{(x_4)} = iB$ and $B^{-1} = B$. Then it
repeats the rule $iK^{-1} = B/\cos z$ with sympy, keeping $\cos z$ as a positive
symbol `c`.

It also defines `check_record(condition, name, record)`, which does what
`check(condition, name, record=record)` of the set-up cell does but prints the PASS
line and the line naming the reproduced Revision record in one piece (Jupyter
sends printed text to the screen in pieces whose boundaries depend on timing;
printing them in one piece keeps the stored output the same in every run).
Before it checks anything, `check_record` asks the helper `record_says_pass` whether
the cited record still says PASS: for a record name of the form
`<report file>, check <check name>` it opens that report (each file once, kept in
the dictionary `REPORT_CHECKS`) and stops the notebook with an error unless a check
of that name exists there with the verdict PASS; a record name without `, check `
names a data entry that the notebook reads and compares itself.
```

In [2]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

## 6. A fermionic Fock space in a few lines

The next cell builds the Fock space of 16 fermion modes $p = 0, 1, \dots, 15$ (mode
$p$ will carry the component $\Psi_{p+1}$). A state is stored as a Python
dictionary `{pattern: amplitude}` that lists only the patterns with a nonzero
amplitude; the vacuum is `{0: 1}` (the pattern 0 has every mode empty).

- `annihilate(p, state)` is $f_p$: in every pattern where mode $p$ is occupied it
```

```
  empties the mode; patterns where it is empty give nothing.
- `create(p, state)` is $f_p^*$: in every pattern where mode $p$ is empty it fills
  the mode.
- Both multiply by $(-1)^{\text{(number of occupied modes below } p)}$. This sign is
  what makes different modes ANTIcommute: exchanging the order in which two modes
  are filled changes the sign of the state.
- `add` forms combinations of states, `inner` is the positive inner product of two
  states, `largest` the largest size of an amplitude (to measure how far a state is
  from zero).
```

In [3]:

```
def sign_below(n, p):
    """(-1) to the power of the number of occupied modes below mode p in pattern n."""

## 7. The canonical field on the Fock space

In this positive Fock space the field component $\Psi_A$ is the annihilator $f_{A-1}$
and its Hilbert adjoint is $\chi_A = f_{A-1}^*$. The CANONICAL conjugate is defined as
$\Psi^\dagger = \chi B$, that is $\Psi^\dagger_A = \sum_C \chi_C B_{CA}$. Then

$$\{\Psi_A, \Psi^\dagger_C\} = \sum_D \{f_{A-1}, f_{D-1}^*\}B_{DC} = B_{AC},$$

the canonical rule of Section 5 (at one point). The next cell checks this for all
256 pairs $(A, C)$ on a random state. Then it checks the Heisenberg equation for a
plane wave: with the Hamiltonian-density matrix $h' = mC - i\sum_a k_a C\gamma^{(x_a)}$
(the matrix of $\Psi^\dagger(\ldots)\Psi$ in the Hamiltonian of a plane wave) the
```

```
operator $H = \Psi^\dagger h'\Psi = \chi(Bh')\Psi$ must satisfy $[H, \Psi_c] =
-(Bh'\Psi)_c$, and $Bh'$ must be the mode Hamiltonian $h = -im\gamma^{(x_4)} -
\gamma^{(x_4)}\sum_a k_a\gamma^{(x_a)}$. Together: $i\,\partial_4\Psi = i \cdot
i[H, \Psi] = h\Psi$, the classical wave equation of the field.
```

## 8. The theorem: the canonical conjugate is not the Hilbert adjoint

The Revision record names an exact column with $Bu = -u$: $u_7 = -i/\sqrt2$,
$u_{16} = 1/\sqrt2$, all other entries 0. The next cell checks $Bu = -u$ and
$u^\dagger Bu = -1$ and builds three operators on the Fock space:
$X = \sum_A u_A^*\Psi_A$, its Hilbert adjoint $X^* = \sum_A u_A\chi_A$, and its
canonical conjugate $X^\dagger = \sum_A u_A\Psi^\dagger_A$. It checks
$\{X, X^*\}\phi = \phi$ (positive, as in every Hilbert space) and $\{X, X^\dagger\}
\phi = -\phi$ (the canonical value $u^\dagger Bu = -1$). So $X^\dagger = -X^*$ here:
the canonical conjugate differs from the Hilbert adjoint.
```

Text cell:

```
The next cell makes the positivity visible. For 300 random normalised states $\phi$
it computes the two lengths $\lVert X\phi\rVert^2$ and $\lVert X^*\phi\rVert^2$.
Each is a squared length, never negative, and their sum is $\langle\phi|\{X,X^*\}|
\phi\rangle = 1$: every point lies on the line $x + y = 1$ in the positive quarter
of the plane. The canonical rule would need the sum $-1$ instead (the dashed line),
which no state of any Hilbert space can reach. The same cell also shows how
indefinite the Krein form is: for 5000 random unit columns $v$ (normal random
numbers, then divided by the length) the ordinary length is always 1, but the
Krein norm $v^\dagger Bv$ is spread between $-1$ and $1$.
```

## 9. The Krein-Fock realisation and the expectation-value rule

The Revision record also describes the other way out: keep $\Psi^\dagger$ as the
canonical conjugate and let the modes have Krein norms $\pm1$. The next cell

- builds 16 Krein-orthonormal modes: 8 eigenvectors of $B$ with eigenvalue $+1$
  ($\epsilon = +1$) and 8 with eigenvalue $-1$ ($\epsilon = -1$), each set made
  orthonormal by the Gram-Schmidt method applied to the columns of the projectors
  $\frac12(I \pm B)$;
- Krein-boosts the first pair, exactly as the record does:
  $u_1' = \frac54u_1 + \frac34u_9$, $u_9' = \frac34u_1 + \frac54u_9$ (with
```

```
  $\cosh t = \frac54$ and $\sinh t = \frac34$, and indeed $\frac{25}{16} -
  \frac{9}{16} = 1$);
- checks $U^\dagger BU = E$ and $UEU^\dagger = B$, where the columns of $U$ are the
  modes and $E = \mathrm{diag}(\epsilon_1, \dots, \epsilon_{16})$;
- realises the Krein-Fock operators on the Fock space as $b_n = f_n$ and
  $b_n^\dagger = \epsilon_n f_n^*$, so that $\{b_n, b_n^\dagger\} = \epsilon_n$, and
  the field as $\Psi = \sum_n u_n b_n$, $\Psi^\dagger = \sum_n u_n^* b_n^\dagger$.
  Then $\{\Psi_A, \Psi^\dagger_C\} = \sum_n\epsilon_n(u_n)_A(u_n)_C^* =
  (UEU^\dagger)_{AC} = B_{AC}$: the same canonical rule.
```

```

Text cell:

```
The next cell draws two pictures of what was just computed. The first shows the
plane spanned by the two modes $u_1$ ($B = +1$) and $u_9$ ($B = -1$) before the
boost. A column $a u_1 + b u_9$ has the ordinary squared length $a^2 + b^2$
(constant on circles) but the Krein norm $a^2 - b^2$ (constant on hyperbolas). The
boosted modes $(\frac54, \frac34)$ and $(\frac34, \frac54)$ lie on the hyperbolas of
Krein norm $+1$ and $-1$, outside the unit circle, and they are Krein-orthogonal:
$\frac54\cdot\frac34 - \frac34\cdot\frac54 = 0$. The second shows the expectation
values of the boosted mode for the 60 random matrices: the Fock-space value against
the rule $\epsilon u^\dagger Mu$ (on the diagonal) and against $u^\dagger BMu$
(scattered away from it).
```

## 10. Maps that keep the anticommutator; the conjugation of the quantised field

**Linear maps.** If $\Psi' = M\Psi$ with a constant matrix $M$, then
$\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{D,F} M_{AD}M_{CF}^*\{\Psi_D, \Psi^\dagger_F\} =
(MBM^\dagger)_{AC}$. The Revision pairing record lists $MBM^\dagger = \sigma B$ with a
sign $\sigma$ for 17 maps: the chirality $\Gamma$, the eight gammas
$\gamma^{(x_a)}$ and the eight reflections $P_a = \Gamma\gamma^{(x_a)}$. A map with
$\sigma = -1$ turns the canonical rule into its negative: the chirality image
$\Gamma\Psi$ of the pairing theorem T1 carries the Krein metric $-B$ (statement Q1
of the quantum reading), while the mirror map $\gamma^{(x_0)}$ of theorem T2 keeps
$+B$.

**Conjugation of the quantised field.** Charge conjugation is a MATRIX map. For the
quantised field it has the form $\Psi^c = M\Psi^{\dagger T}$, that is
$\Psi^c_A = \sum_C M_{AC}\Psi^\dagger_C$. Then, line by line,

$$\{\Psi^c_A, \Psi^{c\dagger}_C\} = \sum_{D,F} M_{AD}M_{CF}^*\{\Psi^\dagger_D,
\Psi_F\} = \sum_{D,F} M_{AD}B_{FD}M_{CF}^* = (MB^TM^\dagger)_{AC}.$$

$B$ is Hermitian and purely imaginary, so $B^T = B^* = -B$. For $M = I$ (the map
$\Psi \to \Psi^{\dagger T}$, which is not a symmetry here) the result is $B^T = -B$:
the sign of the canonical rule is reversed. For $M = \Gamma$ the result is
$\Gamma B^T\Gamma^\dagger = -\Gamma B\Gamma = +B$, because $\Gamma B\Gamma = -B$
($\Gamma$ anticommutes with the five gammas in $B$, an odd number). So the
conjugation of the quantised field that preserves $\{\Psi, \Psi^\dagger\} = B\delta$
is $\Psi \to \Gamma\Psi^{\dagger T}$, and since $\Gamma$ anticommutes with every
gamma it maps the field of mass $m$ to the field of mass $-m$. The next cell checks
all of this. It also counts the checks of the lead-check report
‘Revision/lead_checks/reports/charge-conjugation-and-u1.json‘, which ‘check_record‘
has just read into ‘REPORT_CHECKS‘: there are 12, all with the verdict PASS.
```

maps = {"Gamma": Gamma}
for a in range(8):
    maps[f"gamma^x{a}"] = gamma[a]
    maps[f"P_x{a}"] = Gamma @ gamma[a]  # the reflection P_a = Gamma gamma^(x_a)
```

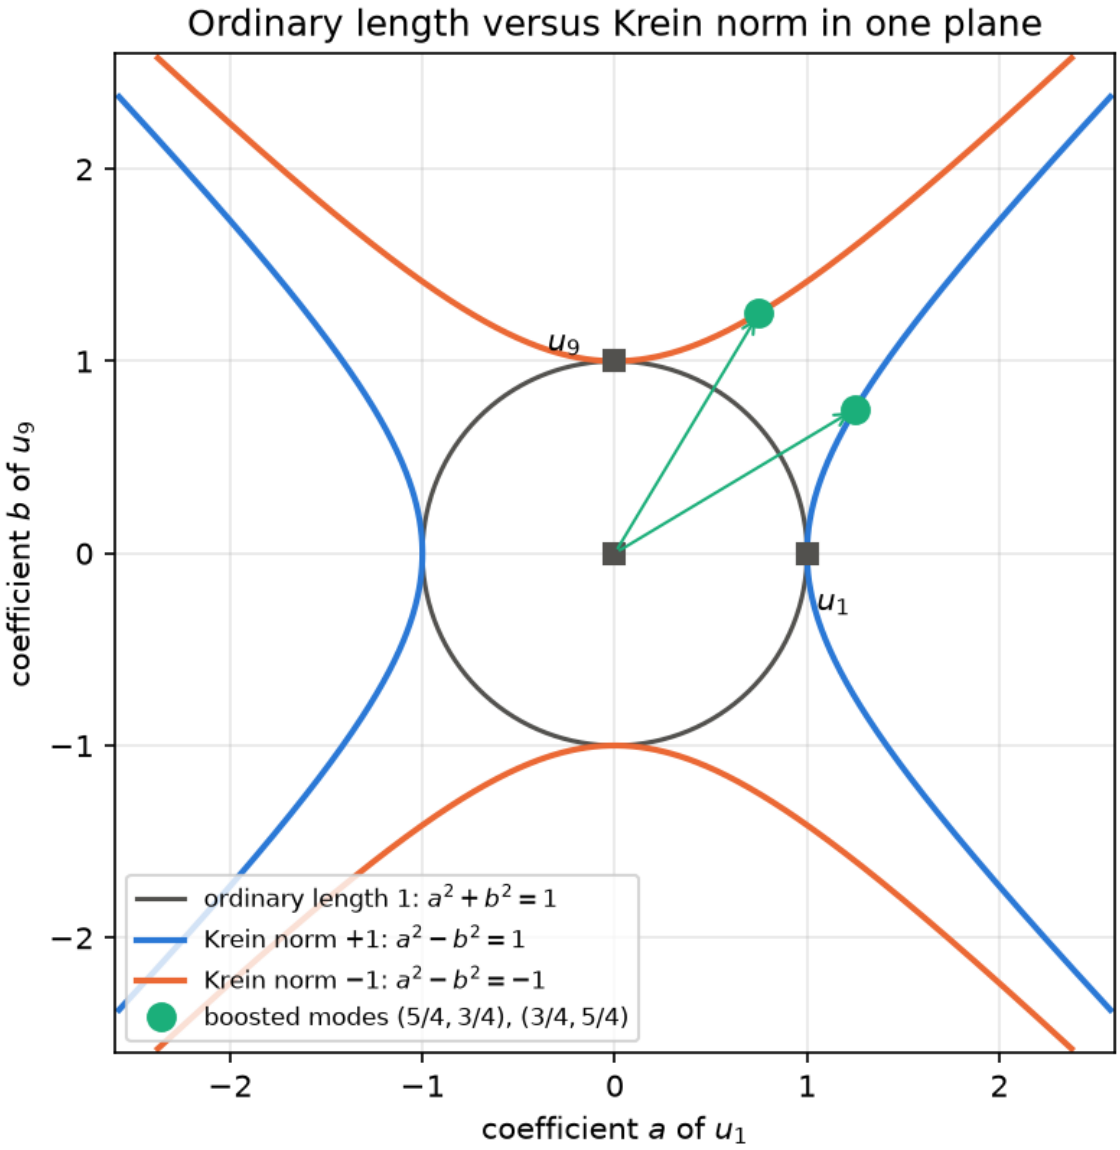

Figure 275: The plane of the columns $au_1 + bu_9$ spanned by a mode u_1 with $Bu_1 = u_1$ and a mode u_9 with $Bu_9 = -u_9$, both of ordinary length 1 (horizontal axis a, vertical axis b, pure numbers). The grey circle holds the columns of ordinary length 1, $a^2 + b^2 = 1$; the blue hyperbola those of Krein norm $a^2 - b^2 = +1$, the orange one those of Krein norm -1. The Krein-boosted modes $(5/4, 3/4)$ and $(3/4, 5/4)$ (green) keep the Krein norms $+1$ and -1 but have the ordinary squared length $34/16$, and they are Krein-orthogonal: $\frac{5}{4} \cdot \frac{3}{4} - \frac{3}{4} \cdot \frac{5}{4} = 0$. (Notebook 10b, figure 3.)

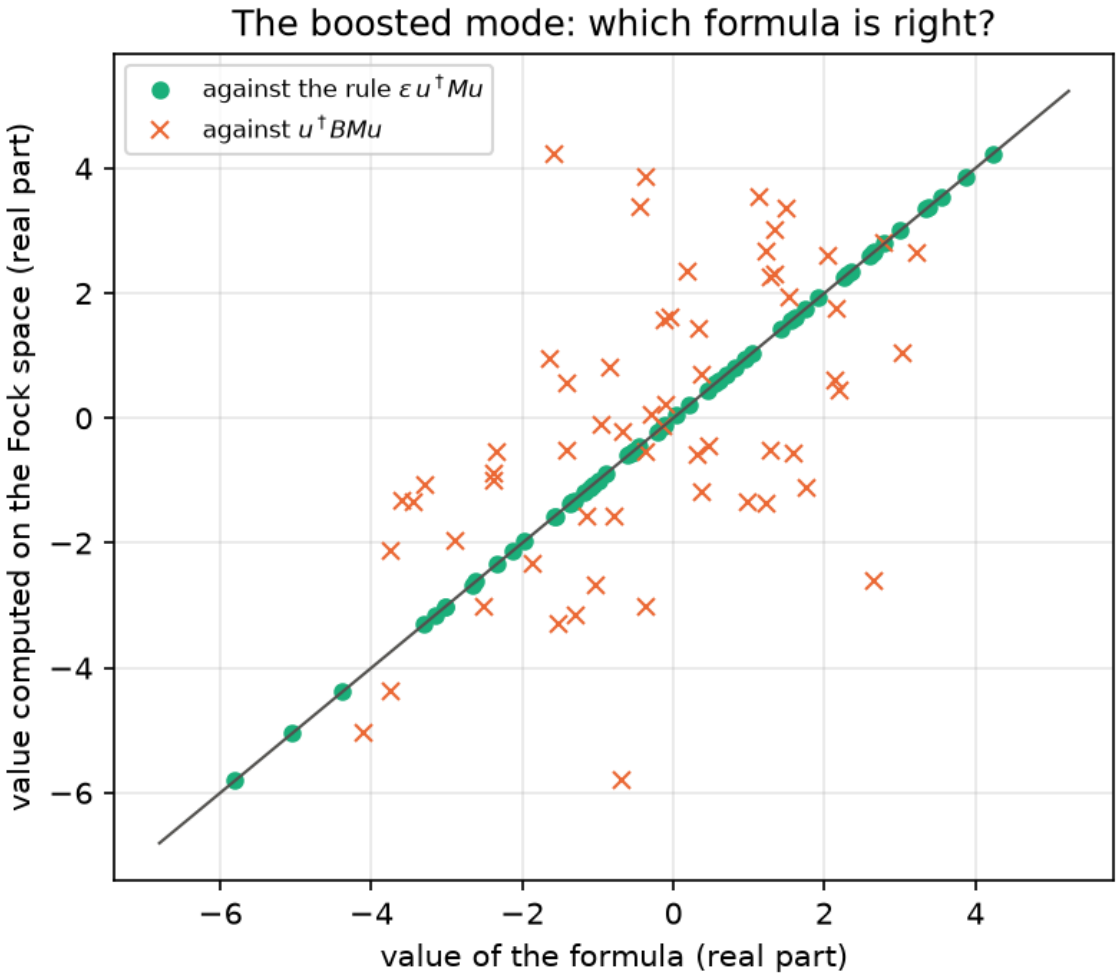

Figure 276: For 60 random complex 16×16 matrices M: the normalised expectation value of $\Psi^\dagger M \Psi$ in the Krein-boosted mode, computed on the Fock space (vertical axis), against the rule $\epsilon u^\dagger M u$ of the Revision record (green dots) and against the formula $u^\dagger BMu$ (orange crosses); horizontal axis: the value of the formula; real parts, pure numbers. The green dots lie exactly on the diagonal; the orange crosses do not, because the boosted mode is not an eigenvector of B. (Notebook 10b, figure 4.)

```
## 12. What this notebook showed

- PROVED (exactly): the time-derivative term of the Lagrangian is
  $\Psi^\dagger K\partial_4\Psi$ with $K = i\cos z\,B$, and the canonical rule
  $\{\Psi, \Psi^\dagger\} = iK^{-1}\delta^7 = B\delta^7/\cos z$.
- CHECKED on an explicit fermionic Fock space (16 modes, 65536 patterns, of which
  only the needed ones are stored): the anticommutation relations, the canonical
  rule with $\Psi^\dagger = \chi B$, and the Heisenberg equation $i\partial_4\Psi =
  h\Psi$ for a plane wave, the classical wave equation of the field.
- PROVED (and checked on the Fock space): because $B$ has the eigenvalue $-1$, the
  canonical conjugate $\Psi^\dagger$ cannot be the Hilbert adjoint of $\Psi$ in a
  space with a positive inner product. The canonical rule defines a Krein space
  with fundamental symmetry $B$; in a positive Hilbert space the canonical
  conjugate is $\Psi^\dagger = \chi B$, with $\chi$ the Hilbert adjoint.
- CHECKED: the Krein-Fock realisation with modes of Krein norm $\pm1$ (including a
  Krein-boosted pair) gives the same rule, and the expectation value in a mode is
  $\epsilon_n u_n^\dagger M u_n$, which equals $u_n^\dagger BMu_n$ only when the mode
  is an eigenvector of $B$.
- PROVED: the chirality image $\Gamma\Psi$ carries $-B$, the mirror image
  $\gamma^{(x_0)}\Psi$ keeps $+B$ (all 17 recorded signs reproduced); the
  conjugation of the quantised field that preserves the canonical rule is the
  MATRIX map $\Psi \to \Gamma\Psi^{\dagger T}$, which reverses the mass; the map
  with $M = I$ would reverse the sign of the rule.
- NOT shown here: a positive state space for the whole field. The next notebook
  builds the positive Fock space of the good sector, one momentum at a time, with
  frozen coefficients.
```

10.19 Line-by-line walk-through of Notebook 10b

The notebook has 12 code cells, In [1] to In [12]. As in Section 10.10, the docstrings of the functions (the text in triple quotes under a `def` line) are left out of the quotations; they are printed in Section 10.18.

In [1], the set-up cell. Its first 248 lines are comments that repeat the run instructions of Section 10.17. The code below the heading THE SET-UP is word for word the code of In [1] of Notebook 10a, explained line by line in Section 10.10, except for one line, `NOTEBOOK_ID = "10b"  # this notebook:  chapter 10, example b`. It defines `REPO`, `OUTPUT_ROOT`, `repository_file`, `output_file`, `say`, `save_figure`, `check`, `report` and `all_checks_passed`, and prints the single line `Set-up of notebook 10b complete:  repository folder found, helpers defined.`

In [2], the time-derivative kernel and the canonical rule.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices
import sympy as sp  # exact algebra with symbols
```

The same imports as In [2] of Notebook 10a: three modules of Python for printing into a buffer, numpy for numbers and sympy for exact algebra.

```
REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"
```

`REPORT_CHECKS` and `record_says_pass` are those of In [2] of Notebook 10a (Section 10.10): for a record name `<report file>, check <check name>` the function reads the report once and answers True only if a check of that name exists there with the verdict PASS; for a data entry of a file that the notebook reads itself it answers True.

```
def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

`check_record` is the function of In [2] of Notebook 10a (Section 10.10): it stops the notebook with an error if the cited record check is missing or not PASS; otherwise it runs `check(condition, name, record=record)`, collects the PASS line and the line naming the reproduced Revision record in a text buffer, and prints both in one piece, so that the stored output is the same in every run.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
gamma = {a: np.array(fixture["gamma"][a], dtype=int) for a in range(8)}
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16
Gamma = (gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5]
         @ gamma[6] @ gamma[7])  # the chirality matrix
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4)
```

The record `Revision/algebra/gammas.json` is read and the eight gammas are stored as whole-number arrays, `gamma[a]` being $\gamma^{(x_a)}$. `C` is $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, `Gamma` the chirality Γ, the product of all eight gammas in the author's order (the parentheses let the product run over two lines), and `B` is $B = -iC\gamma^{(x_4)}$.

```
check(np.array_equal(C @ gamma[4], 1j * B), "C gamma^(x4) = i B")
check(np.array_equal(B @ B, np.eye(16)), "B B = I, so the inverse of B is B")
```

The two facts used in Section 10.12: $C\gamma^{(x_4)} = iB$ and $BB = I_{16}$. Both comparisons are exact (whole numbers times $\pm i$), and two PASS lines are printed.

```
c = sp.Symbol("c", positive=True)  # c stands for cos z, positive on the patch
B_exact = sp.Matrix(16, 16, lambda i, j: sp.I * int(round(B[i, j].imag)))
K = sp.I * c * B_exact  # the kernel of the time-derivative term
rule = (sp.I * K.inv()).applyfunc(sp.simplify)  # the anticommutator matrix i K^-1
```

`c` is a sympy letter for $\cos z$, declared positive (on the patch $0 < z < \pi/2$, $\cos z > 0$). `sp.Matrix(16, 16, lambda i, j: ...)` builds a 16×16 exact matrix entry by entry: entry (i, j) is i times the whole number nearest to the imaginary part of the numpy entry B_{ij} (`round` and `int` turn ± 1.0 into ± 1), so `B_exact` is B with exact entries. `K` is the kernel $K = i \cos z\, B$ of Section 10.12, `K.inv()` its exact inverse, and `rule` is iK^{-1}, every entry simplified.

```
check_record(rule == B_exact / c,
             "exact: i K^(-1) = B / cos z with K = i cos z B",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "first_order_form_and_anticommutator")
```

The check confirms $iK^{-1} = B/\cos z$ exactly, the canonical rule of Section 10.12, and reproduces the Wolfram record check `first_order_form_and_anticommutator`. The cell prints three PASS lines.

In [3], a fermionic Fock space.

```
def sign_below(n, p):
    occupied_below = bin(n & ((1 << p) - 1)).count("1")  # count the 1-digits below p
    return -1 if occupied_below % 2 else 1
```

`sign_below(n, p)` is the sign $(-1)^s$ of Section 10.11, where s is the number of occupied modes below p in the pattern n. The operator written with two less-than signs shifts the binary digits of 1 to the left by p places, which gives 2^p; minus 1 gives the number whose p lowest binary digits are all 1. The operator `&` (binary *and*) keeps a binary digit only where both numbers have a 1, so `n & ...` keeps the digits of n below p. `bin` writes a whole number in binary as a text (for example `bin(9)` is the text `0b1001`), and `.count("1")` counts the digits 1 in it. `occupied_below % 2` is the remainder after division by 2: 1 for an odd count (sign -1), 0 for an even one (sign $+1$; a remainder 0 counts as false in the `if`).

```
def annihilate(p, state):
    result = {}
    for n, amplitude in state.items():
        if n >> p & 1:  # mode p is occupied in the pattern n
            new = n ^ (1 << p)  # the same pattern with mode p emptied
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result
```

`annihilate(p, state)` is f_p. A state is a dictionary `{pattern: amplitude}`, and the loop takes its pairs one by one. The test in the `if` line shifts n to the right by p binary places (the operator of

two greater-than signs) and keeps the last digit (`& 1`): it is 1 exactly when mode p is occupied. Then `^` (binary *exclusive or*) with 2^p flips digit p from 1 to 0: `new` is the pattern with mode p emptied. The amplitude times the sign is added to whatever `result` already holds for `new` (`result.get(new, 0)` is 0 when `new` is not yet there). Patterns in which mode p is empty contribute nothing.

```
def create(p, state):
    result = {}
    for n, amplitude in state.items():
        if not n >> p & 1:  # mode p is empty in the pattern n
            new = n | (1 << p)  # the same pattern with mode p filled
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result
```

`create(p, state)` is f_p^*, the Hilbert adjoint of f_p: it acts only where mode p is empty, and `|` (binary *or*) with 2^p sets digit p to 1. The sign is the same $(-1)^s$.

```
def add(*terms):
    result = {}
    for coefficient, state in terms:
        for n, amplitude in state.items():
            result[n] = result.get(n, 0) + coefficient * amplitude
    return result
```

`add` forms a combination of states. The star in `*terms` lets the function take any number of arguments, each a pair `(coefficient, state)`; the result is the sum of the coefficients times the states, pattern by pattern. For example `add((1, a), (-1, b))` is the state $a - b$.

```
def inner(left, right):
    return sum(np.conj(a) * right.get(n, 0) for n, a in left.items())

def largest(state):
    return max((abs(a) for a in state.values()), default=0.0)
```

`inner(left, right)` is the positive inner product $\langle \text{left}|\text{right}\rangle = \sum_n \text{left}_n^* \, \text{right}_n$ of Section 10.11; `np.conj` is the complex conjugate, and patterns missing from `right` count as amplitude 0. `largest(state)` is the largest size of an amplitude; `default=0.0` returns 0 for the empty dictionary, the zero state. A check of the form "`largest(a - b)` is tiny" says that the states a and b agree.

```
VACUUM = {0: 1.0}
rng = np.random.default_rng(12345)  # random numbers with a fixed seed

def random_state(patterns=6):
    state = {}
    for n in rng.integers(0, 2 ** 16, size=patterns):
        state[int(n)] = complex(rng.normal(), rng.normal())
    length = np.sqrt(inner(state, state).real)
    return {n: a / length for n, a in state.items()}
```

`VACUUM` is the pattern 0 (every mode empty) with amplitude 1. `rng` is a generator of random numbers started with the fixed *seed* 12345, so that every run draws the same numbers and the notebook prints the same output every time. `random_state` picks a few patterns at random (`rng.integers(0, 2 ** 16, size=patterns)` draws whole numbers from 0 up to $2^{16} - 1$), gives each a complex amplitude whose real and imaginary parts are drawn from the normal distribution (`rng.normal()`), and divides by the length, so that the state is normalised.

```
phi = random_state()
worst = 0.0
for p in range(16):
    for q in range(16):
        # {f_p, f_q^*} phi = f_p f_q^* phi + f_q^* f_p phi must be phi (p = q) or 0
        both = add((1, annihilate(p, create(q, phi))),
                   (1, create(q, annihilate(p, phi))))
        expected = phi if p == q else {}
        worst = max(worst, largest(add((1, both), (-1, expected))))
        # {f_p, f_q} phi must be 0
        pair = add((1, annihilate(p, annihilate(q, phi))),
                   (1, annihilate(q, annihilate(p, phi))))
        worst = max(worst, largest(pair))
```

For a random state ϕ the loops test every pair of modes (p, q), $16 \times 16 = 256$ pairs. `both` is $\{f_p, f_q^*\}\phi = f_p f_q^* \phi + f_q^* f_p \phi$ (an operator applied to the result of another is a product of operators), which must be ϕ for $p = q$ and 0 otherwise, as the comment line says; `pair` is $\{f_p, f_q\}\phi$, which must be 0. `worst` keeps the largest deviation seen in the $2 \times 256 = 512$ relations.

```
report("largest violation of the 512 anticommutation relations", f"{worst:.1e}")
check(worst < 1e-14, "the Fock operators obey {f_p, f_q^*} = delta_pq, {f_p, f_q} = 0")
```

The RESULT line shows `0.0e+00`: the relations hold exactly, because the amplitudes are only multiplied by ± 1 and added. The check prints its PASS line.

In [4], the canonical field on the Fock space.

```
def psi(A, state):
    return annihilate(A - 1, state)

def psi_dagger(A, state):
    return add(*[(B[C - 1, A - 1], create(C - 1, state))
                 for C in range(1, 17) if B[C - 1, A - 1] != 0])
```

These are the operators of the positive realisation of Section 10.14: $\Psi_A = f_{A-1}$ (component A uses mode $A - 1$, because the computer counts from 0), and the canonical conjugate $\Psi_A^\dagger = \sum_C \chi_C B_{CA}$ with $\chi_C = f_{C-1}^*$. The list comprehension builds the pairs (coefficient B_{CA}, state f_{C-1}^* applied to the state) for the components C with $B_{CA} \neq 0$ (only one per column, because B has one nonzero entry in every column), and the star in `add(*[...])` passes the list as separate arguments.

```
worst = 0.0
for A in range(1, 17):
```

```
    for C_index in range(1, 17):
        both = add((1, psi(A, psi_dagger(C_index, phi))),
                   (1, psi_dagger(C_index, psi(A, phi))))
        worst = max(worst, largest(add((1, both), (-B[A - 1, C_index - 1], phi))))
report("largest violation of {Psi_A, Psi^dagger_C} = B_AC", f"{worst:.1e}")
check_record(worst < 1e-14, "on the Fock space {Psi_A, Psi^dagger_C} = B_AC (256 pairs)",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "canonical_anticommutator_B")
```

For all 256 pairs (A, C) the loop computes $\{\Psi_A, \Psi_C^\dagger\}\phi$ and subtracts $B_{AC}\phi$ (the name `C_index` avoids overwriting the matrix `C`). The largest deviation is printed as `0.0e+00`, and the check reproduces the record check `canonical_anticommutator_B`: the canonical rule holds on a positive Fock space once $\Psi^\dagger$ is defined as χB.

```
m_value = 1.3  # any mass and momenta (here with momenta along the extra times too)
k = {0: 1.1, 1: 0.4, 2: -0.7, 3: 0.2, 5: 0.9, 6: -0.3, 7: 0.5}
h_prime = m_value * C - 1j * sum(k_a * (C @ gamma[a]) for a, k_a in k.items())
h_mode = -1j * m_value * gamma[4] - sum(k_a * (gamma[4] @ gamma[a])
                                        for a, k_a in k.items())
check(np.max(np.abs(B @ h_prime - h_mode)) < 1e-14,
      "B (m C - i sum_a k_a C gamma^a) equals the mode Hamiltonian h")
```

A mass of 1.3 and momenta along all seven slice directions, including the extra times (the identity holds for all of them). `h_prime` is the Hamiltonian-density matrix $h' = mC - i\sum_a k_a C\gamma^{(x_a)}$ of Section 10.12 and `h_mode` the mode Hamiltonian $h = -im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_a k_a\gamma^{(x_a)}$ of Section 10.3. The check confirms $Bh' = h$, derived line by line in Section 10.12.

```
def hamiltonian(state):
    M = B @ h_prime
    return add(*[(M[c_, d_], create(c_, annihilate(d_, state)))
                 for c_ in range(16) for d_ in range(16) if abs(M[c_, d_]) > 0])
```

`hamiltonian(state)` applies the energy operator $H = \Psi^\dagger h'\Psi = \sum_{A,D}\chi_C B_{CA}h'_{AD}\Psi_D = \sum_{C,D}(Bh')_{CD}\chi_C\Psi_D$ to a state: for each pair of modes (c, d) with a nonzero entry of $M = Bh'$ it takes $f_c^* f_d$ applied to the state (first empty mode d, then fill mode c) with the coefficient M_{cd}. The underscores in `c_` and `d_` only distinguish these names from others.

```
worst = 0.0
for c_ in range(16):
    commutator = add((1, hamiltonian(annihilate(c_, phi))),
                     (-1, annihilate(c_, hamiltonian(phi))))  # [H, Psi_c] phi
    expected = add(*[(-h_mode[c_, d_], annihilate(d_, phi)) for d_ in range(16)])
    worst = max(worst, largest(add((1, commutator), (-1, expected))))
report("largest violation of [H, Psi_c] = -(h Psi)_c", f"{worst:.1e}")
check_record(worst < 1e-12,
             "Heisenberg: i d4 Psi = h Psi, the classical wave equation",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "Heisenberg_equation_reproduces_field_equation")
```

For each component the loop computes $[H, \Psi_c]\phi = H\Psi_c\phi - \Psi_c H\phi$ and compares it with $-(h\Psi)_c\phi = -\sum_d h_{cd}\Psi_d\phi$, the result $[H, \Psi_c] = -(Ah'\Psi)_c$ of Section 10.12 with $A = B$ and $Bh' = h$. The largest deviation is printed as `1.6e-17`, rounding only. By the Heisenberg equation this is $i\,\partial_4\Psi = h\Psi$, the classical wave equation of the field, and the check reproduces the Wolfram record check `Heisenberg_equation_reproduces_field_equation`. The cell prints three PASS lines in all.

In [5], Theorem 10.2 on the recorded column.

```
u = np.zeros(16, dtype=complex)
u[6] = -1j / np.sqrt(2)  # u_7 (the computer counts from 0)
u[15] = 1 / np.sqrt(2)  # u_16
krein_norm_u = (u.conj() @ B @ u).real
report("u^dagger u and u^dagger B u", f"{(u.conj() @ u).real:.12f} and "
       f"{krein_norm_u:.12f}")
```

`np.zeros(16, dtype=complex)` is a column of 16 complex zeros; entries 7 and 16 (positions 6 and 15) are set to $-i/\sqrt{2}$ and $1/\sqrt{2}$, the column of the proof of Theorem 10.2. The RESULT line prints its ordinary squared length $u^\dagger u = 1.000000000000$ and its Krein norm $u^\dagger B u = -1.000000000000$.

```
def X(state):  # X = sum_A conj(u_A) Psi_A
    return add(*[(np.conj(u[A - 1]), psi(A, state)) for A in range(1, 17)])

def X_hilbert(state):  # X^* = sum_A u_A chi_A (the Hilbert adjoint of X)
    return add(*[(u[A - 1], create(A - 1, state)) for A in range(1, 17)])

def X_canonical(state):  # X^dagger = sum_A u_A Psi^dagger_A (canonical conjugate)
    return add(*[(u[A - 1], psi_dagger(A, state)) for A in range(1, 17)])
```

The three operators of Section 10.14: $X = \sum_A u_A^* \Psi_A$, its Hilbert adjoint $X^* = \sum_A u_A \chi_A$ (with $\chi_A = f^*_{A-1}$, the function `create`), and its canonical conjugate $X^\dagger = \sum_A u_A \Psi^\dagger_A$, as the comments say.

```
hilbert = add((1, X(X_hilbert(phi))), (1, X_hilbert(X(phi))))
canonical = add((1, X(X_canonical(phi))), (1, X_canonical(X(phi))))
hilbert_ok = largest(add((1, hilbert), (-1, phi))) < 1e-14  # {X, X^*} = +1
canonical_ok = largest(add((1, canonical), (1, phi))) < 1e-14  # {X, X^dagger} = -1
check_record(np.max(np.abs(B @ u + u)) < 1e-15 and abs(krein_norm_u + 1) < 1e-15
             and hilbert_ok and canonical_ok,
             "B u = -u: {X, X^*} = +1 but the canonical {X, X^dagger} = -1",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "no_positive_inner_product")
```

`hilbert` is $\{X, X^*\}\phi$ and `canonical` is $\{X, X^\dagger\}\phi$. The check requires $Bu = -u$, $u^\dagger B u = -1$, $\{X, X^*\}\phi = +\phi$ and $\{X, X^\dagger\}\phi = -\phi$, and reproduces the record check `no_positive_inner_product`: on a positive space the canonical conjugate is $-X^*$, not X^*, exactly as derived in Section 10.14.

In [6], positivity made visible.

```
lengths = []
for _ in range(300):
    state = random_state(patterns=4)
    x_part, x_star_part = X(state), X_hilbert(state)
    lengths.append((inner(x_part, x_part).real, inner(x_star_part, x_star_part).real))
lengths = np.array(lengths)
sums = lengths.sum(axis=1)
```

For 300 random normalised states (each a combination of 4 random patterns) the loop stores the pair of squared lengths $(\|X\phi\|^2, \|X^*\phi\|^2)$. `np.array` turns the list of pairs into a table with 300 rows and 2 columns, and `.sum(axis=1)` adds the two numbers of each row.

```
report("smallest and largest |X phi|^2 + |X^* phi|^2",
       f"{sums.min():.12f} and {sums.max():.12f}")
check(np.all(lengths >= 0) and np.max(np.abs(sums - 1)) < 1e-12,
      "positivity: |X phi|^2 + |X^* phi|^2 = 1 for every random state")
```

By Section 10.11, $\|X\phi\|^2 + \|X^*\phi\|^2 = \langle\phi|\{X, X^*\}\phi\rangle = \langle\phi|\phi\rangle = 1$. The printed smallest and largest sums are both `1.000000000000`, and the check requires every squared length to be ≥ 0 and every sum to be 1.

```
columns = rng.normal(size=(5000, 16)) + 1j * rng.normal(size=(5000, 16))
columns = columns / np.linalg.norm(columns, axis=1, keepdims=True)  # unit length
krein_norms = np.einsum("ni,ij,nj->n", columns.conj(), B, columns).real
```

5000 random complex columns with 16 entries (one per row of the table `columns`) are drawn and each is divided by its length (`np.linalg.norm(..., axis=1, keepdims=True)` computes the length of every row and keeps it as a column, so that the division acts row by row). `np.einsum("ni,ij,nj->n", ...)` computes, for each row n, the sum $\sum_{i,j} v_i^* B_{ij} v_j = v^\dagger B v$: the letters name the indices, and the indices that do not appear after the arrow are summed over.

```
report("smallest and largest Krein norm of the 5000 unit columns",
       f"{krein_norms.min():.3f} and {krein_norms.max():.3f}")
check(krein_norms.min() < -0.5 and krein_norms.max() > 0.5
      and np.all(np.abs(krein_norms) <= 1 + 1e-12),
      "random unit columns have Krein norms of both signs, all between -1 and 1")
```

The printed range is from `-0.777` to `0.704`. A Krein norm of a unit column can never lie outside $[-1, 1]$, because the eigenvalues of B are ± 1; the check requires values below -0.5 and above 0.5 (both signs) and none outside that interval.

```
fig, ax = plt.subplots(figsize=(6.0, 4.6))
ax.plot(lengths[:, 0], lengths[:, 1], "o", color="#2a78d6", markersize=4,
        label="300 random states $\\phi$")
line = np.linspace(-1.4, 1.2, 2)
ax.plot(line, 1 - line, color="#52514e", linewidth=1, label="$x + y = 1$")
ax.plot(line, -1 - line, "--", color="#eb6834", linewidth=2,
        label="$x + y = -1$ (canonical rule)")
```

The first picture: each random state is a blue dot at $x = \|X\phi\|^2$, $y = \|X^*\phi\|^2$. `line` holds the two end points -1.4 and 1.2 of a horizontal range, and the two `plot` calls draw the straight lines $y = 1 - x$ (grey) and $y = -1 - x$ (orange, dashed): the line on which the dots lie, and the line on which they would have to lie if the canonical conjugate were the Hilbert adjoint.

```
ax.set_xlim(-1.4, 1.2)
ax.set_ylim(-1.4, 1.2)
ax.set_xlabel("$x = \\|X\\phi\\|^2$")
ax.set_ylabel("$y = \\|X^*\\phi\\|^2$")
ax.set_title("Squared lengths are never negative")
ax.legend(loc="lower left")
save_figure(fig, "positivity",
...)
```

The ranges of both axes are fixed so that the negative quarter, where the dashed line runs, is visible. Figure 1 of Notebook 10b shows all 300 dots on the grey line, inside the quarter where both squared lengths are positive, and the orange dashed line far away in the region of negative values that no state can reach: this is Theorem 10.2 in one picture.

```
fig, ax = plt.subplots()
ax.set_axisbelow(True)  # draw the grid lines behind the bars
ax.hist(krein_norms, bins=50, range=(-1, 1), color="#2a78d6", edgecolor="white")
ax.axvline(0.0, color="#52514e", linewidth=1)
ax.set_xlabel("Krein norm $v^\\dagger B v$ of a random column with $v^\\dagger v = 1$")
ax.set_ylabel("number of columns (of 5000)")
ax.set_title("The Krein form is indefinite: both signs occur")
save_figure(fig, "krein_norms_random",
...)
```

The second picture is a **histogram**: `ax.hist` divides the interval from -1 to 1 into 50 equal bins and draws one bar per bin, as tall as the number of Krein norms that fall into it. Figure 2 of Notebook 10b shows a bell-shaped distribution centred at 0 and symmetric: every random unit column has the ordinary length 1, but its Krein norm is positive about as often as negative, and usually small, because a random column mixes the eight directions of positive and the eight of negative charge.

In [7], the Krein-Fock realisation.

```
def orthonormal_columns(P):
    basis = []
    for column in P.T:
        v = column.astype(complex)
        for _ in range(2):
            for e in basis:
                v = v - (e.conj() @ v) * e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:
            basis.append(v / length)
    return np.array(basis).T
```

This is the Gram-Schmidt function `orthonormal_basis` of In [10] of Notebook 10a under another name (Section 10.10): it returns orthonormal columns that span the range of the matrix P, removing from each column of P its parts along the columns found so far (twice, to remove rounding errors) and keeping what is left, divided by its length, when anything is left.

```
plus_modes = orthonormal_columns((np.eye(16) + B) / 2)  # B u = +u, 8 columns
minus_modes = orthonormal_columns((np.eye(16) - B) / 2)  # B u = -u, 8 columns
U = np.hstack([plus_modes, minus_modes]).astype(complex)  # 16 modes as columns
epsilon = np.array([1.0] * 8 + [-1.0] * 8)  # their Krein norms
```

$\frac{1}{2}(I_{16} \pm B)$ are the projectors onto the eigenspaces of B for $+1$ and -1 (by $BB = I_{16}$, the argument of Section 10.5). Their orthonormal columns are 8 modes with $Bu = u$ and 8 with $Bu = -u$; `U` holds the 16 modes as its columns, and `epsilon` their Krein norms $+1$ (eight times) and -1 (eight times).

```
cosh_t, sinh_t = 5 / 4, 3 / 4  # a Krein boost of the modes 1 and 9
first, ninth = U[:, 0].copy(), U[:, 8].copy()
U[:, 0] = cosh_t * first + sinh_t * ninth
U[:, 8] = sinh_t * first + cosh_t * ninth
E = np.diag(epsilon)
```

The Krein boost of Section 10.14 with $\cosh t = \frac{5}{4}$, $\sinh t = \frac{3}{4}$ replaces mode 1 by $\frac{5}{4}u_1 + \frac{3}{4}u_9$ and mode 9 by $\frac{3}{4}u_1 + \frac{5}{4}u_9$. `.copy()` keeps the old columns, so that the second line still uses the old first column. `E` is the diagonal matrix $E = \mathrm{diag}(\epsilon_1, \ldots, \epsilon_{16})$.

```
gram_ok = np.max(np.abs(U.conj().T @ B @ U - E)) < 1e-14  # U^dagger B U = E
complete_ok = np.max(np.abs(U @ E @ U.conj().T - B)) < 1e-14  # U E U^dagger = B
report("squared ordinary length of the boosted mode 1",
       f"{np.linalg.norm(U[:, 0]) ** 2:.6f}")
check(gram_ok and complete_ok,
      "Krein-orthonormal modes: U^dagger B U = E and U E U^dagger = B")
```

The check confirms the two matrix identities of Section 10.14, $U^\dagger B U = E$ (the boosted modes are still Krein-orthonormal) and $UEU^\dagger = B$. The RESULT line prints the squared ordinary length of the boosted mode, `2.125000`, which is $\frac{34}{16}$.

```
def b(n, state):  # b_n = f_n
    return annihilate(n, state)

def b_dagger(n, state):  # b_n^dagger = epsilon_n f_n^*
    return add((epsilon[n], create(n, state)))
```

On the positive Fock space the Krein-Fock operators are realised as $b_n = f_n$ and $b_n^\dagger = \epsilon_n f_n^*$, so that $\{b_n, b_n^\dagger\} = \epsilon_n \{f_n, f_n^*\} = \epsilon_n$, the rule of Section 10.14.

```
def krein_psi(A, state):  # Psi_A = sum_n (u_n)_A b_n
    return add(*[(U[A - 1, n], b(n, state)) for n in range(16)])
```

```
def krein_psi_dagger(A, state):  # Psi^dagger_A = sum_n conj((u_n)_A) b_n^dagger
    return add(*[(np.conj(U[A - 1, n]), b_dagger(n, state)) for n in range(16)])
```

The field $\Psi = \sum_n u_n b_n$ and its conjugate $\Psi^\dagger = \sum_n u_n^\dagger b_n^\dagger$, component by component; `U[A - 1, n]` is entry A of the mode u_{n+1}.

```
worst = 0.0
for A in range(1, 17):
    for C_index in range(1, 17):
        both = add((1, krein_psi(A, krein_psi_dagger(C_index, phi))),
                   (1, krein_psi_dagger(C_index, krein_psi(A, phi))))
        worst = max(worst, largest(add((1, both), (-B[A - 1, C_index - 1], phi))))
report("Krein-Fock: largest violation of {Psi_A, Psi^dagger_C} = B_AC", f"{worst:.1e}")
check(worst < 1e-13, "Krein-Fock realisation: {Psi, Psi^dagger} = B again")
```

As in In [4], all 256 anticommutators are compared with B_{AC}. The largest deviation is printed as `1.6e-16`: the Krein-Fock realisation gives the same canonical rule. The cell prints two PASS lines.

In [8], the expectation-value rule.

```
def expectation(n, M):
    excited = b_dagger(n, VACUUM)  # b_n^dagger |0>
    acted = {}
    for A in range(1, 17):
        psi_part = krein_psi(A, excited)
        for C_index in range(1, 17):
            if M[C_index - 1, A - 1] != 0:
                acted = add((1, acted), (M[C_index - 1, A - 1],
                                         krein_psi_dagger(C_index, psi_part)))
    numerator = inner(VACUUM, b(n, acted))  # <0| b_n ... |0>, a number
    norm = inner(VACUUM, b(n, excited))  # <0| b_n b_n^dagger |0> = epsilon_n
    return numerator / norm
```

`expectation(n, M)` computes the left side of the normalised rule of Section 10.14. `excited` is the state $b_n^\dagger|0\rangle$. The double loop applies $\Psi^\dagger M \Psi = \sum_{C,A} M_{CA} \Psi_C^\dagger \Psi_A$ to it: for each A it computes Ψ_A applied to the excited state once (`psi_part`), and adds $M_{CA}\Psi_C^\dagger$ applied to that. Then b_n is applied and the result is projected on the vacuum: `numerator` is $\langle 0|b_n(\Psi^\dagger M \Psi)b_n^\dagger|0\rangle$ and `norm` is $\langle 0|b_n b_n^\dagger|0\rangle = \epsilon_n$, as the comments say. The function returns their quotient.

```
rule_errors, naive_errors, points = [], [], []
for _ in range(60):
    M = rng.normal(size=(16, 16)) + 1j * rng.normal(size=(16, 16))
    for n in (3, 0):  # mode 4 (unboosted) and mode 1 (boosted), counted from 0
        value = expectation(n, M)
        rule = epsilon[n] * (U[:, n].conj() @ M @ U[:, n])
        naive = U[:, n].conj() @ B @ M @ U[:, n]
        rule_errors.append(abs(value - rule))
        if n == 3:
```

```
            naive_errors.append(abs(value - naive))
        else:
            points.append((value.real, rule.real, naive.real))
points = np.array(points)
```

For 60 random complex matrices M and two modes, mode 4 (not boosted, an eigenvector of B) and mode 1 (boosted), the loop compares the Fock-space value with the rule $\epsilon_n u_n^\dagger M u_n$ and with the form $u_n^\dagger BMu_n$. The deviations from the rule are collected for both modes; the deviations from $u^\dagger BMu$ only for mode 4, where it must also hold; for the boosted mode the three real parts are stored for the figure.

```
naive_boosted = np.max(np.abs(points[:, 0] - points[:, 2]))
report("largest |Fock value - epsilon u^dagger M u| (both modes)",
       f"{max(rule_errors):.1e}")
report("boosted mode: largest |Fock value - u^dagger B M u|", f"{naive_boosted:.2f}")
check_record(max(rule_errors) < 1e-12 and max(naive_errors) < 1e-12
             and naive_boosted > 0.1,
             "expectation rule eps u^dagger M u; u^dagger B M u fails if boosted",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "expectation_value_rule")
```

The printed lines show the deviation from the rule, `1.3e-15` (rounding only), and the deviation of the form $u^\dagger BMu$ for the boosted mode, `5.82`: large. The check requires both and reproduces the record check `expectation_value_rule`.

In [9], two pictures of the Krein-Fock realisation.

```
fig, ax = plt.subplots(figsize=(6.0, 6.0))
angle = np.linspace(0, 2 * np.pi, 400)
ax.plot(np.cos(angle), np.sin(angle), color="#52514e", linewidth=1.5,
        label="ordinary length 1: $a^2 + b^2 = 1$")
```

In the plane of the columns $au_1 + bu_9$ (with $Bu_1 = u_1$, $Bu_9 = -u_9$, both of length 1 and orthogonal) the ordinary squared length is $a^2 + b^2$ and the Krein norm is $a^2 - b^2$. The points $(\cos\theta, \sin\theta)$ for 400 angles from 0 to 2π draw the grey unit circle, the columns of ordinary length 1.

```
t = np.linspace(-1.6, 1.6, 400)
for side in (1, -1):  # the two branches of each hyperbola
    ax.plot(side * np.cosh(t), np.sinh(t), color="#2a78d6", linewidth=2,
            label="Krein norm $+1$: $a^2 - b^2 = 1$" if side == 1 else None)
    ax.plot(np.sinh(t), side * np.cosh(t), color="#eb6834", linewidth=2,
            label="Krein norm $-1$: $a^2 - b^2 = -1$" if side == 1 else None)
```

Since $\cosh^2 t - \sinh^2 t = 1$, the points $(\pm\cosh t, \sinh t)$ lie on the **hyperbola** $a^2 - b^2 = 1$ (blue, the columns of Krein norm $+1$) and the points $(\sinh t, \pm\cosh t)$ on $a^2 - b^2 = -1$ (orange). Each hyperbola has two branches, drawn by the two passes of the loop; only the first pass labels the curves (`None` gives no legend entry).

```
ax.plot([0, 1, 0], [1, 0, 0], "s", color="#52514e", markersize=7)
ax.annotate("$u_1$", (1.0, 0.0), xytext=(1.05, -0.3))
ax.annotate("$u_9$", (0.0, 1.0), xytext=(-0.35, 1.05))
ax.plot([1.25, 0.75], [0.75, 1.25], "o", color="#1baf7a", markersize=9,
        label="boosted modes $(5/4, 3/4)$, $(3/4, 5/4)$")
for x_end, y_end in ((1.25, 0.75), (0.75, 1.25)):
    ax.annotate("", xy=(x_end, y_end), xytext=(0, 0),
                arrowprops={"arrowstyle": "->", "color": "#1baf7a"})
```

Grey squares mark the origin and the two unboosted modes, $u_1 = (1, 0)$ and $u_9 = (0, 1)$, which `annotate` labels. Green dots mark the boosted modes $(\frac{5}{4}, \frac{3}{4})$ and $(\frac{3}{4}, \frac{5}{4})$, and an annotation without text but with `arrowprops` draws an arrow from the origin to each.

```
ax.set_xlim(-2.6, 2.6)
ax.set_ylim(-2.6, 2.6)
ax.set_aspect("equal")
ax.set_xlabel("coefficient $a$ of $u_1$")
ax.set_ylabel("coefficient $b$ of $u_9$")
ax.set_title("Ordinary length versus Krein norm in one plane")
ax.legend(loc="lower left", fontsize=8)
save_figure(fig, "krein_plane",
...)
```

`set_aspect("equal")` gives both axes the same scale, so that the circle looks round. Figure 3 of Notebook 10b shows the boosted modes outside the unit circle (their ordinary length is larger than 1) but exactly on the hyperbolas of Krein norm $+1$ and -1: a Krein boost keeps the Krein norms and changes the ordinary lengths, as a Lorentz boost keeps $t^2 - x^2$ and changes t and x.

```
fig, ax = plt.subplots(figsize=(6.0, 5.0))
ax.plot(points[:, 1], points[:, 0], "o", color="#1baf7a", markersize=5,
        label="against the rule $\\epsilon\\,u^\\dagger M u$")
ax.plot(points[:, 2], points[:, 0], "x", color="#eb6834", markersize=6,
        label="against $u^\\dagger B M u$")
low, high = points.min() - 1, points.max() + 1
ax.plot([low, high], [low, high], color="#52514e", linewidth=1)
ax.set_xlabel("value of the formula (real part)")
ax.set_ylabel("value computed on the Fock space (real part)")
ax.set_title("The boosted mode: which formula is right?")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "expectation_rule",
...)
```

The second picture plots, for the boosted mode and the 60 random matrices, the Fock-space value (vertical) against the rule (green dots) and against $u^\dagger BMu$ (orange crosses), with the grey diagonal from a little below the smallest to a little above the largest value. Figure 4 of Notebook 10b shows the green dots exactly on the diagonal and the orange crosses scattered around it: the rule of the record is right, the form $u^\dagger BMu$ is right only for modes that are eigenvectors of B.

In [10], maps that keep the canonical rule, and the conjugation.

```
pairing = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                     .read_text(encoding="utf-8"))
rows = pairing["data"]["Krein_signs_M_B_Mdagger"]
maps = {"Gamma": Gamma}
for a in range(8):
    maps[f"gamma^x{a}"] = gamma[a]
    maps[f"P_x{a}"] = Gamma @ gamma[a]  # the reflection P_a = Gamma gamma^(x_a)
```

The pairing record is read, and `rows` is its list of 17 entries, each holding the name of a map and the recorded sign. The dictionary `maps` pairs the same names with the matrices: the chirality, the eight gammas and the eight reflections $P_a = \Gamma\gamma^{(x_a)}$.

```
signs, agree = [], True
for row in rows:
    M = maps[row["map"]]
    transformed = M @ B @ M.conj().T  # M B M^dagger
    sign = (1 if np.array_equal(transformed, B)
            else -1 if np.array_equal(transformed, -B) else 0)
    signs.append(sign)
    agree = agree and sign == row["sign"]
names = [row["map"] for row in rows]  # the names of the 17 maps in the record
```

For each recorded map the loop computes $MBM^\dagger$ exactly and reads off its sign: $+1$ if it equals B, -1 if it equals $-B$, and 0 otherwise (which never happens). `agree` stays true while every computed sign equals the recorded one.

```
say("map: sign sigma in M B M^dagger = sigma B")
say(", ".join(f"{name}: {s:+d}" for name, s in zip(names, signs)))
check_record(agree and len(rows) == 17,
             "the Krein signs of all 17 recorded maps are reproduced",
             record="Revision/pairing/pairing-theory.json, data "
                    "Krein_signs_M_B_Mdagger")
```

The format code `+d` prints a whole number with its sign. The printed list is the table of Section 10.15: `Gamma: -1`, the gammas of x_0 to x_3 and x_7 with $+1$, those of x_5 to x_7 with -1, the reflections P_1 to P_4 and P_0 with -1 and P_5 to P_7 with $+1$. The check reproduces the record's data.

```
check_record(np.array_equal(Gamma @ B @ Gamma.T, -B),
             "the chirality image Gamma Psi carries the Krein metric -B",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.image_krein_metric")
check_record(np.array_equal(gamma[0] @ B @ gamma[0].T, B),
             "the mirror image gamma^(x0) Psi keeps +B",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.T2_image_keeps_B")
```

The two maps of the pairing theorems separately: $\Gamma B\Gamma^T = -B$ and $\gamma^{(x_0)}B(\gamma^{(x_0)})^T = +B$ (for real matrices the conjugate transpose is the transpose). They reproduce the sympy record checks `Q.image_krein_metric` and `Q.T2_image_keeps_B`.

```
identity = np.eye(16)
conjugation_identity = identity @ B.T @ identity.conj().T  # M = I
conjugation_gamma = Gamma @ B.T @ Gamma.conj().T  # M = Gamma
check(np.array_equal(B.T, -B), "B^T = -B (B is Hermitian and purely imaginary)")
check_record(np.array_equal(conjugation_gamma, B)
             and np.array_equal(conjugation_identity, -B),
             "Psi -> Gamma Psi^(dagger T) keeps B; with M = I one gets -B",
             record="Revision/lead_checks/reports/charge-conjugation-and-u1.json, "
                    "check quantum_charge_conjugation_unitary_type")
```

The conjugations of the quantised field, $\Psi \to M\Psi^{\dagger T}$, change the canonical matrix into $MB^TM^\dagger$ (Section 10.15). The cell checks $B^T = -B$, then $\Gamma B^T \Gamma^\dagger = +B$ and $I_{16} B^T I_{16} = -B$, and reproduces the lead check `quantum_charge_conjugation_unitary_type`.

```
lead_file = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
lead_verdicts = list(REPORT_CHECKS[lead_file].values())  # read by check_record
passed = lead_verdicts.count("PASS")
report("checks of charge-conjugation-and-u1.json with the verdict PASS",
       f"{passed} of {len(lead_verdicts)}")
check(lead_verdicts == ["PASS"] * 12,
      "the lead-check report charge-conjugation-and-u1.json holds 12 checks, all PASS")
```

The previous `check_record` has just read the lead-check report into the dictionary `REPORT_CHECKS` of In [2]. `REPORT_CHECKS[lead_file].values()` are the verdicts of all its checks, and `list(...)` makes a list of them; `lead_verdicts.count("PASS")` counts the entries equal to `PASS`. The RESULT line prints `12 of 12`, and the check confirms that the report holds exactly 12 checks, all with the verdict PASS (`["PASS"] * 12` is the list of twelve such entries): the number of checks that the table of records in Section 10.1 gives for this report.

```
mass_reversed = all(np.array_equal(Gamma @ gamma[a] @ Gamma, -gamma[a])
                    for a in range(8))
check(mass_reversed, "Gamma anticommutes with every gamma: the conjugation reverses m")
```

$\Gamma\gamma^{(x_a)}\Gamma = -\gamma^{(x_a)}$ for all eight gammas, which is the reason why $\Gamma\Psi^*$ obeys the equation of mass $-m$ (Section 10.15). The cell prints seven PASS lines.

In [11], the signs as a bar chart.

```
labels = [row["map"].replace("gamma^x", "g").replace("P_x", "P") for row in rows]
labels = [lab if lab != "Gamma" else "Gam" for lab in labels]
colours = ["#2a78d6" if s > 0 else "#eb6834" for s in signs]
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0),
                         gridspec_kw={"width_ratios": [4, 1]})
for ax in axes:
    ax.set_axisbelow(True)  # draw the grid lines behind the bars
```

Short labels are made from the recorded names (`gamma^x1` becomes `g1`, `P_x1` becomes `P1`, and `Gamma` becomes `Gam`), and each bar gets blue for the sign $+1$ and orange for -1. The figure has two panels; `width_ratios` makes the first four times as wide as the second.

```
axes[0].bar(range(len(signs)), signs, color=colours, width=0.7)
axes[0].set_xticks(range(len(signs)), labels)
axes[0].axhline(0, color="#52514e", linewidth=1)
axes[0].set_ylim(-1.4, 1.4)
axes[0].set_yticks([-1, 0, 1])
axes[0].set_ylabel("sign $\\sigma$ in $M B M^\\dagger = \\sigma B$")
axes[0].set_title("linear maps $\\Psi \\to M\\Psi$")
```

The left panel draws one bar of height $+1$ or -1 per map, labelled under the axis.

```
conjugation_signs = [-1, 1]  # M = I gives -B, M = Gamma gives +B
axes[1].bar([0, 1], conjugation_signs, color=["#eb6834", "#2a78d6"], width=0.6)
axes[1].set_xticks([0, 1], ["$M = I$", "$M = \\Gamma$"])
axes[1].axhline(0, color="#52514e", linewidth=1)
axes[1].set_ylim(-1.4, 1.4)
axes[1].set_yticks([-1, 0, 1])
axes[1].set_title("$\\Psi \\to M\\Psi^{\\dagger T}$")
save_figure(fig, "krein_signs",
...)
```

The right panel draws the two conjugations, with the signs just checked in In [10]. Figure 5 of Notebook 10b shows five orange bars among the gammas and reflections (Γ, $\gamma^{(x_5)}$ to $\gamma^{(x_7)}$ and five reflections) and, on the right, the orange bar of $M = I$ next to the blue bar of $M = \Gamma$: only the conjugation $\Psi \to \Gamma\Psi^{\dagger T}$, which reverses the mass, keeps the canonical rule.

In [12], the last check.

```
for name in ("10b_1_positivity.png", "10b_2_krein_norms_random.png",
             "10b_3_krein_plane.png", "10b_4_expectation_rule.png",
             "10b_5_krein_signs.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The loop checks that each of the five figure files exists, and the last line prints ALL 25 CHECKS PASSED (notebook 10b): the five figure checks and the 20 checks of the cells before (3 in In [2], 1 in In [3], 3 in In [4], 1 in In [5], 2 in In [6], 2 in In [7], 1 in In [8] and 7 in In [10]).

10.20 The good sector: a positive Fock space for one momentum

Theorem 10.2 forbids a positive inner product with $\Psi^\dagger$ read as the Hilbert adjoint, and Theorem 10.1 says that even the one-particle waves of real frequency mix the two signs of charge four and four. Yet the Revision record constructs, in the **good sector** (no momentum along the extra times, $k_5 = k_6 = k_7 = 0$), a POSITIVE quantum state space for each single momentum with frozen coefficients (flat-frame plane waves, in which the deflation of the extra times does not enter), with particles and antiparticles of positive energy. This section derives it line by line; the scope is stated at its end.

The waves of one good-sector momentum. In the good sector the mode Hamiltonian is

$$h = m\beta + \sum_{a=1,2,3,8} k_a \alpha^a, \qquad \beta = -i\gamma^{(x_4)}, \qquad \alpha^a = -\gamma^{(x_4)}\gamma^{(x_a)}.$$

All five matrices are Hermitian (Section 10.4), so h is Hermitian. By Section 10.4, $hh = E^2 I_{16}$ with $E = \sqrt{m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2} > 0$ and $\operatorname{tr} h = 0$, so h has the eigenvalue $+E$ eight times and $-E$ eight times. Choose orthonormal eigenvectors $u_1, \ldots, u_8$ with $hu_s = Eu_s$ and $v_1, \ldots, v_8$ with $hv_s = -Ev_s$ (for example by the Gram-Schmidt method applied to the columns of the projectors $\frac{1}{2}(I_{16} \pm h/E)$ of Section 10.5). A u and a v are orthogonal:

$$E\, v^\dagger u = v^\dagger h u = (h^\dagger v)^\dagger u = (hv)^\dagger u = -E\, v^\dagger u,$$

by $hu = Eu$, the rule $(Xv)^\dagger = v^\dagger X^\dagger$, $h^\dagger = h$ and $hv = -Ev$ (E is real); so $2E\, v^\dagger u = 0$ and $v^\dagger u = 0$. The 16×16 matrix $W = (u_1, \ldots, u_8, v_1, \ldots, v_8)$ therefore has orthonormal columns, $W^\dagger W = I_{16}$. Then W is invertible with $W^{-1} = W^\dagger$, and so also $WW^\dagger = I_{16}$, which written out is the **completeness** relation $\sum_s u_s u_s^\dagger + \sum_s v_s v_s^\dagger = I_{16}$.

The field on a positive Fock space. Take 16 fermion modes on a positive Fock space, called $b_1, \ldots, b_8$ (particles) and $d_1, \ldots, d_8$ (antiparticles), with $\{b_s, b_{s'}^*\} = \{d_s, d_{s'}^*\} = \delta_{ss'}$ and all other anticommutators zero, and put

$$\Psi = \sum_s \left(u_s\, b_s + v_s\, d_s^*\right), \qquad \chi = \sum_s \left(u_s^\dagger\, b_s^* + v_s^\dagger\, d_s\right), \qquad \Psi^\dagger = \chi B.$$

χ (a row of 16 operators) is the Hilbert adjoint of Ψ, and $\Psi^\dagger = \chi B$ is the positive realisation of Section 10.14. Line by line:

$$\{\Psi_A, \chi_C\} = \sum_s (u_s)_A (u_s)_C^* \{b_s, b_s^*\} + \sum_s (v_s)_A (v_s)_C^* \{d_s^*, d_s\}$$

$$= \sum_s (u_s)_A (u_s)_C^* + \sum_s (v_s)_A (v_s)_C^* = (WW^\dagger)_{AC} = \delta_{AC}.$$

The first step keeps only the anticommutators of an operator with its own adjoint (all others vanish); the second uses $\{b_s, b_s^*\} = \{d_s^*, d_s\} = 1$; the third recognises the product $WW^\dagger$; the fourth is completeness. Then, exactly as in Section 10.14, $\{\Psi_A, \Psi_C^\dagger\} = \sum_D \{\Psi_A, \chi_D\} B_{DC} = B_{AC}$: the canonical rule holds.

The energy, line by line. By Section 10.12 the energy of the momentum is $H = \Psi^\dagger h' \Psi = \chi B h' \Psi = \chi h \Psi$. Since $h\Psi = \sum_s (Eu_s b_s - Ev_s d_s^*)$,

$$\chi h \Psi = \sum_{s,s'} \left(u_{s'}^\dagger b_{s'}^* + v_{s'}^\dagger d_{s'}\right)\left(Eu_s b_s - Ev_s d_s^*\right) = \sum_s E\, b_s^* b_s - \sum_s E\, d_s d_s^*.$$

The second step multiplies out and uses the orthonormality: $u_{s'}^\dagger u_s = v_{s'}^\dagger v_s = \delta_{ss'}$ and $u_{s'}^\dagger v_s = v_{s'}^\dagger u_s = 0$ (the numbers stand in front of the operators). Now $d_s d_s^* = 1 - d_s^* d_s$ by the anticommutator, for each of the 8 values of s:

$$H = \sum_s E\left(b_s^* b_s + d_s^* d_s\right) - 8E.$$

The **vacuum** $|0\rangle$ is the state with $b_s|0\rangle = d_s|0\rangle = 0$ for all s. Its energy is $-8E$: in the old picture of Dirac, every one of the 8 negative-energy levels $-E$ is filled, the filled **Dirac sea**. **Normal ordering** is the prescription that drops this constant: the normal-ordered energy is the energy minus that of the vacuum,

$$:H: = \sum_s E\left(b_s^* b_s + d_s^* d_s\right) \geq 0.$$

A **particle** $b_s^*|0\rangle$ and an **antiparticle** $d_s^*|0\rangle$ (a hole in the filled sea) both have the energy $+E > 0$.

The charge. $Q = \Psi^\dagger B \Psi = \chi B B \Psi = \chi\Psi$, and the same steps with h replaced by I_{16} give

$$\chi\Psi = \sum_s \left(b_s^* b_s + d_s d_s^*\right) = \sum_s \left(b_s^* b_s - d_s^* d_s\right) + 8.$$

After normal ordering a particle has the charge $+1$ and an antiparticle -1.

Counting the states of one momentum. A pattern with N_b occupied particle modes and N_d occupied antiparticle modes is an eigenstate of both operators: its normal-ordered energy is $E(N_b + N_d)$ and its normal-ordered charge is $N_b - N_d$ (each $b_s^* b_s$ and $d_s^* d_s$ counts whether its mode is occupied). The number of ways to choose j occupied modes out of 8 is the **binomial coefficient** $\binom{8}{j} = \frac{8!}{j!\,(8-j)!}$, where $n! = 1 \cdot 2 \cdots n$ and $0! = 1$; for example $\binom{8}{0} = 1$, $\binom{8}{1} = 8$ and $\binom{8}{4} = \frac{40320}{24 \cdot 24} = 70$. So $\binom{8}{N_b}\binom{8}{N_d}$ patterns have the given N_b and N_d, and the total is $\sum_{N_b}\binom{8}{N_b}\sum_{N_d}\binom{8}{N_d} = 2^8 \cdot 2^8 = 65536$. Only the vacuum ($N_b = N_d = 0$) has the energy 0; $8 + 8 = 16$ states have one quantum; the largest group, $\binom{8}{4}^2 = 4900$ states, has 8 quanta and the charge 0. No state has a negative normal-ordered energy.

statement	**status**	**where it is verified**
good sector, one momentum with frozen coefficients: positive Fock space, $\Psi^\dagger = \chi B$, $\{\Psi, \Psi^\dagger\} = B$; vacuum $-8E$; every quantum $+E$; charges ± 1	PROVED (derivation above) and checked for $m = 2$, $k = (k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$ (vacuum -40) and for $m = 3$, $k_1 = 4$, $E = 5$	`python-field-theory.json`, check `good_sector_positive_fock_realisation`; `wolfram-field-theory.json`, check `Fock_space_good_sector_example`
normal ordering (dropping the vacuum value)	ASSUMED	a prescription, as in Dirac's theory

statement	status	where it is verified
scope: single good-sector momenta, in flat 4+4 space or in the frozen-coefficient model of Section 10.3 (ASSUMED: it leaves out the hidden-direction terms, including the connection term $3H\gamma^{(x_0)}$)	OPEN beyond it	a positive-norm Hilbert space for the whole field in the deflating background, the extra-time sector and the operator theory for $\lambda \neq 0$ beyond the finite model of Section 10.21 are not constructed; in the author's metric the curved good-sector mode operator is Hermitian only up to a boundary term at $z = \pi/2$ (Section 10.27; Revision theory document, section 11)

10.21 The expectation-value rule and the energy-momentum tensor operator

The rule in the positive realisation. Every classical bilinear $\Psi^\dagger M \Psi$ becomes the operator $\chi BM\Psi$. Write $N = BM$ and insert the expansion:

$$\chi N\Psi = \sum_{s,s'} \Big[(u_{s'}^\dagger N u_s)\, b_{s'}^* b_s + (u_{s'}^\dagger N v_s)\, b_{s'}^* d_s^* + (v_{s'}^\dagger N u_s)\, d_{s'} b_s + (v_{s'}^\dagger N v_s)\, d_{s'} d_s^* \Big].$$

In the particle state $b_1^*|0\rangle$ the second and third kinds of terms change the number of quanta by two and have expectation value 0; the first kind gives $u_1^\dagger N u_1$; the fourth gives $\sum_s v_s^\dagger N v_s$, which is also its vacuum value and is removed by normal ordering. So the normal-ordered expectation value is $u_1^\dagger BMu_1$. In the antiparticle state $d_1^*|0\rangle$ the first kind gives 0, and the fourth gives $\sum_{s\neq 1} v_s^\dagger N v_s$ (the term $s = 1$ vanishes, because $d_1^* d_1^*|0\rangle = 0$); minus the vacuum value this is $-v_1^\dagger N v_1$. Hence the **expectation-value rule** of the Revision record:

$$\langle :\Psi^\dagger M \Psi: \rangle = u^\dagger BMu \text{ (particle)}, \qquad \langle :\Psi^\dagger M \Psi: \rangle = -v^\dagger BMv \text{ (antiparticle)}.$$

Two examples: for $M = B$ (the charge) the rule gives $u^\dagger BBu = u^\dagger u = 1$ and $-v^\dagger v = -1$; for $M = h' = Bh$ (the energy) it gives $u^\dagger BBhu = u^\dagger hu = E$ and $-v^\dagger hv = -(-E) = E$.

The energy-momentum tensor operator. The energy-momentum tensor of Chapter 9 becomes an operator by replacing the field by the quantised field and normal ordering with respect to the good-sector modes (Revision record `Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`, section 12):

$$\hat{T}^\nu{}_\mu(x) = :T^\nu{}_\mu\big[\hat{\Psi}, \hat{\bar{\Psi}}\big]:, \qquad \hat{\bar{\Psi}} = \hat{\Psi}^\dagger C, \qquad \hat{\Psi}^\dagger = \hat{\chi} B.$$

With $\hat{S} = \hat{\Psi}^\dagger C \hat{\Psi}$ and the kinetic terms $\hat{K}_\mu = \frac{1}{2f_\mu}(\hat{\bar{\Psi}}\gamma^{(\mu)}\partial_\mu\hat{\Psi} - \partial_\mu\hat{\bar{\Psi}}\gamma^{(\mu)}\hat{\Psi})$, the energy density and the pressures are

$$\hat{\rho} = -\hat{T}^{x_4}{}_{x_4} = :\Big(- \sum_{\mu \neq x_4} \hat{K}_\mu + m\hat{S} + U(\hat{S})\Big):, \qquad \hat{p}_\mu = \hat{T}^{\mu}{}_{\mu} = :\Big(\sum_{\nu \neq \mu} \hat{K}_\nu - m\hat{S} - U(\hat{S})\Big): \quad (\mu \neq x_4),$$

with the kinetic part $:(-\sum_{\mu \neq x_4} \hat{K}_\mu):$ and the potential part $:(m\hat{S} + U(\hat{S})):$ of the energy density. For $\lambda = 0$ every component is a normal-ordered bilinear, and its one-particle expectation values follow the rule just derived. For $\lambda \neq 0$ the potential term is quartic in the field, and the expectation value of $:U(S):$ is not U of the expectation value of $:S:$ in general.

The case $\lambda \neq 0$ in a finite model. The operator form of the on-shell identity $\sum_\mu \langle :K_\mu: \rangle = \langle :(m + U')S: \rangle$, and with it $\rho = mS + U$ and $p = SU' - U$, is verified by the Revision record in one finite model only (`Revision/theory/fock_quartic/`, one Python checker with sympy and an exact engine for the anticommutation rules, no Wolfram counterpart; 21 of 21 checks pass). The model is the positive Fock space of Section 10.20 ($\Psi^\dagger = \chi B$) for one good-sector plane-wave mode set with frozen coefficients: flat frame, volume 1, 16 modes and 2^{16} states, at rest ($k = 0$, symbolic m) and for $m = 3$, $k = (4, 0, 0, 0)$. There, for solutions of the interacting operator field equation, $:\sum_\mu K_\mu: = :(m + U'(S))S:$ holds as an exact operator identity on every state if and only if the potential $U = \frac{\lambda}{2}:SS:$ and the energy-momentum tensor are both Wick (normal) ordered, and at rest $\hat{\rho} = :mS + U:$ and $\hat{p} = :SU' - U:$ hold in the same sense (checks `trace_identity_operator_identity_wick` and `homogeneous_rho_p_operator_identities_wick`). Every other tested combination (four orderings of the potential, two definitions of the left-hand side, two right-hand sides; 30 combinations on the two mode sets) violates the identity by a nonzero one-body operator, sometimes plus a constant, that is linear in λ (check `trace_identity_fails_for_every_other_combination`), and it fails already in expectation values: at rest on every state except the vacuum of the mode set (check `expectation_classes_M0`), and for $k = (4, 0, 0, 0)$ in a state with a single particle or a single antiparticle (check `expectation_values_M1`). An occupation state with n quanta at rest has $\rho = mn + \frac{\lambda}{2}n(n-1)$ and $p = \frac{\lambda}{2}n(n-1)$, so $\langle :U(S): \rangle = \frac{\lambda}{2}n(n-1)$ differs from $U(\langle :S: \rangle) = \frac{\lambda}{2}n^2$ (check `homogeneous_expectation_values_are_not_U_of_expectation`). For the field on a whole slice (many momenta), for the curved x_0 dependence with its boundary term at $z = \pi/2$ and for the extra-time sector the operator form stays OPEN, and symmetry and conservation of the quartic operator are not verified. Numerical expectation values of $\hat{T}$ for many-fermion states of the field on a whole slice are computed only in the Kohn-Sham approximation (Chapters 14 and 15); the finite model gives none for a physical many-fermion state.

operator form of the on-shell identity for $\lambda \neq 0$ (at rest also $\hat{\rho} = :mS + U:$, $\hat{p} = :SU' - U:$)	PROVED (exact, sympy and an exact engine for the anticommutation rules) in the finite model of one good-sector mode set with frozen coefficients only, where, of the tested orderings, it holds if and only if U and $\hat{T}$ are Wick ordered; OPEN for the field on a whole slice, the curved x_0 dependence and the extra-time sector; symmetry and conservation of the quartic operator not verified	`fock-quartic.json`, checks `trace_identity_operator_identity_wick`, `trace_identity_fails_for_every_other_combination` and `homogeneous_rho_p_operator_identities_wick`

10.22 The commuting field dirac16complex00: an energy unbounded below

The second field of the theory, dirac16complex00 (written Φ), has 16 COMMUTING complex components. The author defines it as a classical ("semi-classical") field, the analogue of Dirac's wave function of 1928, and the Revision record does not quantise it. Without anticommutators there is no Pauli principle, no filled sea and no normal ordering, and its classical energy is not positive.

The energy density of one plane wave, line by line. Take flat space, $U = 0$ and a positive-frequency plane wave $\Phi = c\,u\,e^{i(k\cdot x - Ex_4)}$ of the good sector, with $hu = Eu$, $E > 0$, a complex number c and $k \cdot x = \sum_{a\neq 4} k_a x_a$. The energy density is $\rho = -T^{x_4}{}_{x_4} = -\sum_{\mu\neq x_4} K_\mu + mS$ (Chapter 9), with $K_a = \frac{1}{2}(\bar{\Phi}\gamma^{(x_a)}\partial_a\Phi - \partial_a\bar{\Phi}\gamma^{(x_a)}\Phi)$, $S = \bar{\Phi}\Phi$ and $\bar{\Phi} = \Phi^\dagger C$.

- $\partial_a\Phi = ik_a\Phi$, and $\partial_a\bar{\Phi} = (\partial_a\Phi)^\dagger C = -ik_a\bar{\Phi}$, because the conjugate of ik_a is $-ik_a$ (the derivative of the exponential, and the conjugate transpose of a number times a column).
- So $K_a = \frac{1}{2}(ik_a + ik_a)\bar{\Phi}\gamma^{(x_a)}\Phi = ik_a|c|^2\,u^\dagger C\gamma^{(x_a)}u$, because in $\bar{\Phi}\gamma^{(x_a)}\Phi$ the exponentials $e^{-i(\ldots)}$ and $e^{+i(\ldots)}$ cancel and $c^*c = |c|^2$; in the same way $S = |c|^2 u^\dagger Cu$.
- Therefore $\rho = |c|^2\,u^\dagger\big(mC - i\sum_a k_a C\gamma^{(x_a)}\big)u = |c|^2\,u^\dagger h'u$, with the matrix h' of Section 10.12.
- From $Bh' = h$ and $BB = I_{16}$ follows $h' = Bh$ (multiply by B from the left), and $hu = Eu$ gives $u^\dagger h'u = u^\dagger Bhu = E\,u^\dagger Bu$:

$$\rho = E\,|c|^2\,u^\dagger Bu.$$

The charge density is $\Phi^\dagger B\Phi = |c|^2 u^\dagger B u$. In the good sector B commutes with h, and by Theorem 10.1 the eigenspace of $+E$ contains four orthonormal columns with $Bu = u$ and four with $Bu = -u$. The first four have $\rho = +E|c|^2$, the other four $\rho = -E|c|^2$, although all eight have the positive frequency E. Multiplying the wave by a large number c makes its energy density as negative as one likes: **the classical energy of dirac16complex00 is unbounded below**, already for $U = 0$ in the good sector, and its charge density $\Phi^\dagger B\Phi$ is an indefinite form. For its charge, as for that of dirac16complex (Section 10.2), only the local conservation law is proved; the total over a slice is constant only if no charge flows through the boundary, which at $z = \pi/2$ is an ASSUMED no-flux condition that the record does not impose (`wolfram-field-theory.json`, check `charge_density_is_Krein_form_C`). Dirac's wave function of 1928 has the positive density $\psi^\dagger\psi$; dirac16complex00 does not. For the recorded momentum $m = 2$, $k = (k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$ and $|c| = 1$ the energy densities are $+5$ and -5 and the charge densities $+1$ and -1 (`python-scope.json`, check `commuting_field_energy_unbounded_below`). Quantising the fermion field with anticommutators and normal ordering makes the good-sector energy positive; for the classical commuting field there is no such mechanism, and no quantum statement is made for dirac16complex00 in this book.

10.23 Example: Notebook 10c builds the positive Fock space of one momentum

Notebook 10c builds the good-sector waves of the recorded momentum $m = 2$, $k = (k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$, the positive Fock space with the operators b_s and d_s, and the field Ψ with $\Psi^\dagger = \chi B$ (Section 10.20); it checks the canonical rule, computes the vacuum energy -40, the normal-ordered energies $+5$ and charges ± 1 of all 16 one-quantum states, checks the expectation-value rule of Section 10.21 for 100 random matrices and for the second recorded momentum $m = 3$, $k_1 = 4$, counts all 65536 states of one momentum, and computes the energy densities ± 5 of the commuting field (Section 10.22). It draws five figures and ends with the line ALL 14 CHECKS PASSED (notebook 10c).

10.24 How to run Notebook 10c

Step 1. What this notebook does and what it needs.

Notebook 10c (The good sector: a positive Fock space for one momentum) is the file `Revision/textbook/notebooks/10c_good_sector_fock.ipynb` of the repository Dirac_claude. For one momentum without extra-time components (the good sector) it computes the orthonormal eigenvectors of the Hermitian mode Hamiltonian, expands the field in particle and antiparticle operators on a positive fermionic Fock space with the canonical conjugate realised as chi B, and checks the canonical anticommutator, the vacuum energy of the filled Dirac sea (minus 8 E), the normal-ordered energies (plus E for particles and for antiparticles), the charges (plus 1 and minus 1) and the expectation-value rule, for the two exact examples of the Revision record; it counts the states of all 65536 occupation patterns by energy and charge, and contrasts the quantised fermion with the classical commuting field dirac16complex00, whose energy is unbounded below; five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10c_good_sector_fock.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10c_good_sector_fock.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10c_good_sector_fock.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10c.captions.json`
- `Revision/textbook/figures/10c_1_expectation_rule.png`
- `Revision/textbook/figures/10c_2_dirac_sea.png`
- `Revision/textbook/figures/10c_3_fock_spectrum.png`
- `Revision/textbook/figures/10c_4_commuting_energy.png`
- `Revision/textbook/figures/10c_5_energy_density_spread.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10c_5_energy_density_spread.png exists
ALL 14 CHECKS PASSED (notebook 10c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10c_good_sector_fock.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10c_good_sector_fock.ipynb
python -m nbconvert --execute --inplace 10c_good_sector_fock.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.25 Notebook 10c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10c_good_sector_fock.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The previous notebooks of this chapter showed that the canonical rule
```

$\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$ (at one point) forces an indefinite inner product when $\Psi^\dagger$ is read as the Hilbert adjoint. The Revision record shows that in the *good sector* (waves that do not depend on the extra times x_5, x_6, x_7) a POSITIVE quantum state space exists for each single momentum with frozen coefficients (flat-frame plane waves, in which the deflation of the extra times does not enter). This notebook builds it, for one momentum at a time, and checks every recorded number:

- the mode Hamiltonian h of a good-sector momentum is Hermitian, with eigenvalues $+E$ and $-E$ (eight each), $E = \sqrt{m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2}$;
- the field is expanded in particle operators b_s and antiparticle operators d_s on a positive Fock space, and the canonical conjugate is realised as $\Psi^\dagger = \chi B$ with χ the Hilbert adjoint; then $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$ holds;
- the vacuum (the *filled Dirac sea*) has energy $-8E$; after *normal ordering* a particle and an antiparticle both have energy $+E$, and charges $+1$ and -1;
- the expectation-value rule $\langle{:}\Psi^\dagger M\Psi{:}\rangle = u^\dagger BMu$ for a particle and $-v^\dagger BMv$ for an antiparticle;
- all $2^{16} = 65536$ occupation patterns of one momentum, counted by energy and charge;
- the contrast with the classical COMMUTING field dirac16complex00, which has no Fock space and no normal ordering: its positive-frequency waves have energy densities of both signs, so its energy is unbounded below.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 10c (The good sector: a positive Fock space for one momentum) is the file ‘Revision/textbook/notebooks/10c_good_sector_fock.ipynb‘ of the repository Dirac_claude. For one momentum without extra-time components (the good sector) it computes the orthonormal eigenvectors of the Hermitian mode Hamiltonian, expands the field in particle and antiparticle operators on a positive fermionic Fock space with the canonical conjugate realised as chi B, and checks the canonical anticommutator, the vacuum energy of the filled Dirac sea (minus 8 E), the normal-ordered energies (plus E for particles and for antiparticles), the charges (plus 1 and minus 1) and the expectation-value rule, for the two exact examples of the Revision record; it counts the states of all 65536 occupation patterns by energy and charge, and contrasts the quantised fermion with the classical commuting field dirac16complex00, whose energy is unbounded below; five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any

terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned

versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10c_good_sector_fock.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10c_good_sector_fock.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10c_good_sector_fock.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10c.captions.json‘
- ‘Revision/textbook/figures/10c_1_expectation_rule.png‘
- ‘Revision/textbook/figures/10c_2_dirac_sea.png‘
- ‘Revision/textbook/figures/10c_3_fock_spectrum.png‘
- ‘Revision/textbook/figures/10c_4_commuting_energy.png‘
- ‘Revision/textbook/figures/10c_5_energy_density_spread.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10c_5_energy_density_spread.png exists
ALL 14 CHECKS PASSED (notebook 10c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10c_good_sector_fock.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 10c_good_sector_fock.ipynb
  python -m nbconvert --execute --inplace 10c_good_sector_fock.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.

- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 10c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10c (The good sector: a positive Fock space for one momentum) is the file
# Revision/textbook/notebooks/10c_good_sector_fock.ipynb of the repository Dirac_claude.
# For one momentum without extra-time components (the good sector) it computes the
# orthonormal eigenvectors of the Hermitian mode Hamiltonian, expands the field in
# particle and antiparticle operators on a positive fermionic Fock space with the
# canonical conjugate realised as chi B, and checks the canonical anticommutator, the
# vacuum energy of the filled Dirac sea (minus 8 E), the normal-ordered energies (plus E
# for particles and for antiparticles), the charges (plus 1 and minus 1) and the
# expectation-value rule, for the two exact examples of the Revision record; it counts
# the states of all 65536 occupation patterns by energy and charge, and contrasts the
# quantised fermion with the classical commuting field dirac16complex00, whose energy is
# unbounded below; five teaching figures. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
```

```
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
```

```
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
```

```
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10c_good_sector_fock.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10c_good_sector_fock.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10c_good_sector_fock.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10c.captions.json
# - Revision/textbook/figures/10c_1_expectation_rule.png
# - Revision/textbook/figures/10c_2_dirac_sea.png
# - Revision/textbook/figures/10c_3_fock_spectrum.png
# - Revision/textbook/figures/10c_4_commuting_energy.png
# - Revision/textbook/figures/10c_5_energy_density_spread.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
```

```
#
#     PASS the figure file 10c_5_energy_density_spread.png exists
#     ALL 14 CHECKS PASSED (notebook 10c)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10c_good_sector_fock.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10c_good_sector_fock.ipynb
#     python -m nbconvert --execute --inplace 10c_good_sector_fock.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
```

## 3. The words used in this notebook

- **Good sector**: no momentum along the extra times, $k_5 = k_6 = k_7 = 0$.
- **Mode Hamiltonian** $h$: the $16 \times 16$ matrix with $i\,du/dx_4 = hu$ for a
  plane wave $u\,e^{ik\cdot x}$ (built in the first notebook of this chapter); its
  eigenvalues are the frequencies, read as energies.
- **Orthonormal**: columns $u_s$ with $u_s^\dagger u_{s'} = 1$ for $s = s'$ and 0
  otherwise. **Completeness**: 16 orthonormal columns $w_1, \dots, w_{16}$ satisfy
  $\sum_n w_n w_n^\dagger = I_{16}$.
- **Particle, antiparticle**: a quantum of positive energy created by $b_s^*$, and
  a quantum created by $d_s^*$, which is a hole in the filled negative-energy levels.
- **Dirac sea**: the picture in which every negative-energy level is filled in the
  vacuum. Its energy, $-E$ for each of the 8 negative levels, is $-8E$.
- **Normal ordering**: writing every product with the annihilators to the right, by
  definition dropping the constant that the reordering produces (here $-8E$ for the
  energy). The normal-ordered value of an operator $X$ in a state is its value minus
  the vacuum value.
- **Charge**: the U(1) charge $Q = \Psi^\dagger B\Psi$ of the field (its density, an
  indefinite form). Its local conservation law is proved; the total over a slice is
  constant only if no charge flows through the boundary, which at $z = \pi/2$ is an
  ASSUMED no-flux condition that the Revision record does not impose.
- **Expectation value**: $\langle\phi|X|\phi\rangle$ in a normalised state $\phi$.
- **Fock space, pattern, vacuum, $f_p$, $f_p^*$**: as in the previous notebook of
  this chapter: a basis state is a pattern of occupations of 16 fermion modes,
  stored as a whole number whose binary digit $p$ is the occupation of mode $p$.
- **dirac16complex00**: the second field of the theory, with 16 COMMUTING complex
  components; it is a classical field (it is not quantised).
- **Energy density**: $\rho = -T^{x_4}{}_{x_4}$, the time-time component of the
  energy-momentum tensor with the sign convention of the Revision record.
```

Text cell:

```
## 4. The physical and mathematical situation

**One good-sector momentum.** In the good sector $h = m\beta + \sum_{a}k_a\alpha^a$
with $\beta = -i\gamma^{(x_4)}$ and $\alpha^a = -\gamma^{(x_4)}\gamma^{(x_a)}$ for
$a = 1, 2, 3, 8$; all five matrices are Hermitian, so $h$ is Hermitian and has real
eigenvalues; $h^2 = E^2 I_{16}$ and $\mathrm{tr}\,h = 0$ give eight eigenvalues $+E$
and eight $-E$. Choose orthonormal eigenvectors $u_1, \dots, u_8$ ($hu_s = Eu_s$) and
$v_1, \dots, v_8$ ($hv_s = -Ev_s$). Eigenvectors of a Hermitian matrix for different
eigenvalues are orthogonal, so the 16 columns are orthonormal, and the matrix $W$
with these columns obeys $WW^\dagger = I_{16}$ (completeness).

**The field.** On a positive Fock space with operators $b_s, d_s$ ($\{b_s, b_{s'}^*\}
= \{d_s, d_{s'}^*\} = \delta_{ss'}$, all other anticommutators zero) put

$$\Psi = \sum_s (u_s b_s + v_s d_s^*),\qquad \chi = \sum_s (u_s^\dagger b_s^* +
v_s^\dagger d_s),\qquad \Psi^\dagger = \chi B .$$

Here $\chi$ is the Hilbert adjoint of $\Psi$. Line by line:
$\{\Psi_A, \chi_C\} = \sum_s (u_s)_A(u_s)_C^* + \sum_s (v_s)_A(v_s)_C^* =
(WW^\dagger)_{AC} = \delta_{AC}$, and therefore $\{\Psi_A, \Psi^\dagger_C\} = \sum_D
\{\Psi_A, \chi_D\}B_{DC} = B_{AC}$: the canonical rule.

**The energy.** The Hamiltonian of the momentum is $\Psi^\dagger h'\Psi$ with
$h' = mC - i\sum_a k_aC\gamma^{(x_a)}$, and $Bh' = h$ (previous notebook), so it
equals $\chi h\Psi$. Insert the expansion; $hu_s = Eu_s$, $hv_s = -Ev_s$ and the
orthonormality leave

$$\chi h\Psi = \sum_s E\,b_s^*b_s - \sum_s E\,d_sd_s^* = \sum_s E\,(b_s^*b_s +
d_s^*d_s) - 8E,$$

where the last step used $d_sd_s^* = 1 - d_s^*d_s$ for each of the 8 values of $s$.
The vacuum ($b_s|0\rangle = d_s|0\rangle = 0$) has energy $-8E$; after normal
ordering every particle and every antiparticle has energy $+E > 0$.

**The charge.** $Q = \Psi^\dagger B\Psi = \chi BB\Psi = \chi\Psi = \sum_s(b_s^*b_s +
d_sd_s^*) = \sum_s(b_s^*b_s - d_s^*d_s) + 8$: after normal ordering particles have
charge $+1$ and antiparticles $-1$.

**The commuting field.** For dirac16complex00 there is no Fock space and no
normal ordering. For a plane wave $\Phi = c\,u\,e^{i(k\cdot x - Ex_4)}$ with
$hu = Eu$ the energy density is $\rho = E\,|c|^2\,u^\dagger Bu$ (derived in
Section 10), and $u^\dagger Bu$ takes both signs on the eigenspace of $+E$: the
classical energy is unbounded below.
```

Text cell:

```
## 5. The gamma matrices, $B$ and the mode Hamiltonian

The next cell reads the gammas, builds $C$ and $B$, defines the mode Hamiltonian
$h$ of a good-sector momentum and the helper ‘check_record‘ (the PASS line and the
line of the reproduced Revision record are printed in one piece, so that the stored
output is the same in every run), and the colours of the figures.
Before it checks anything, ‘check_record‘ asks the helper ‘record_says_pass‘ whether
```

the cited record still says PASS: for a record name of the form
‘<report file>, check <check name>‘ it opens that report (each file once, kept in
the dictionary ‘REPORT_CHECKS‘) and stops the notebook with an error unless a check
of that name exists there with the verdict PASS; a record name without ‘, check ‘
names a data entry that the notebook reads and compares itself.

In [2]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices

```

Text cell:

```
## 6. One good-sector momentum: $m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$

The sympy verifier of the Revision record uses the mass $m = 2$ and the momenta
$k_1 = 1$, $k_2 = 2$, $k_3 = 0$, $k_0 = 4$, so $E = \sqrt{4 + 1 + 4 + 0 + 16} = 5$.
The next cell builds $h$, checks that it is Hermitian, that $h^2 = 25 I_{16}$ and
that it commutes with $B$, and computes the eigenvectors as the orthonormal columns
of the projectors $\frac12(I \pm h/E)$ (the same procedure as in the first notebook
of this chapter). It then checks orthonormality and completeness, $W^\dagger W =
WW^\dagger = I_{16}$, where $W = (u_1, \dots, u_8, v_1, \dots, v_8)$.
```

In [3]:

## 7. The positive Fock space and the field operators

The next cell copies the fermionic Fock space of the previous notebook (states are
dictionaries `{pattern: amplitude}`; `annihilate(p, state)` is $f_p$ and
`create(p, state)` is $f_p^*$, with the sign that makes different modes
anticommute). The 16 modes are used as follows: modes $p = 0, \dots, 7$ are the
particles, $b_{s} = f_{s-1}$; modes $p = 8, \dots, 15$ are the antiparticles,
$d_s = f_{s+7}$. The field $\Psi = \sum_s (u_sb_s + v_sd_s^*)$ is then
$\Psi_A = \sum_p W_{Ap}F_p$ with $F_p = f_p$ for $p < 8$ and $F_p = f_p^*$ for
$p \geq 8$, and its Hilbert adjoint is $\chi_A = \sum_p W_{Ap}^*F_p^*$.

Every operator of the form $\chi N\Psi = \sum_{A,C}\chi_A N_{AC}\Psi_C$ becomes
$\sum_{p,q} (W^\dagger NW)_{pq}F_p^*F_q$; the function `bilinear(N, state)` applies
it to a state. The cell checks $\{\Psi_A, \chi_C\} = \delta_{AC}$ and
$\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$ on a random state.
```

## 9. The expectation-value rule, and the second recorded example

In the positive realisation every classical bilinear $\Psi^\dagger M\Psi$ becomes
$\chi BM\Psi$. For the particle state $b_s^*|0\rangle$ only the term
$(u_s^\dagger BMu_s)\,b_s^*b_s$ contributes after normal ordering, so the
normal-ordered expectation value is $u_s^\dagger BMu_s$; for the antiparticle state
$d_s^*|0\rangle$ the term $(v_s^\dagger BMv_s)\,d_sd_s^* = (v_s^\dagger BMv_s)(1 -
d_s^*d_s)$ gives $-v_s^\dagger BMv_s$. The next cell checks both for 100 random
complex matrices $M$ and draws the result.
```

## 10. All 65536 states of one momentum, and the picture of the Dirac sea

A pattern $n$ with $N_b$ occupied particle modes and $N_d$ occupied antiparticle
modes is an eigenstate of the energy and of the charge: by Section 4 its
normal-ordered energy is $E(N_b + N_d)$ and its normal-ordered charge is
$N_b - N_d$. The next cell checks this on 200 random patterns with the Fock-space
operators, then counts all 65536 patterns by energy and charge (the number of
patterns with given $N_b$ and $N_d$ is $\binom{8}{N_b}\binom{8}{N_d}$, where
$\binom{8}{j}$ counts the ways to choose $j$ of 8 modes), and draws two figures: the
classical energies $\pm E$ of the waves against the momentum (with the filled sea),
and the counts of the quantum states.
```

In [8]:

```

## 11. The contrast: the classical commuting field dirac16complex00

The field dirac16complex00 has 16 COMMUTING components and is not quantised. Its
energy density, with the sign convention of the Revision record, is
$\rho = -T^{x_4}{}_{x_4} = -\sum_{\mu \neq x_4}K_\mu + mS$ for $U = 0$, with
$K_\mu = \frac12(\bar\Phi\gamma^{(\mu)}\partial_\mu\Phi - \partial_\mu\bar\Phi
\gamma^{(\mu)}\Phi)$ in flat space and $S = \bar\Phi\Phi$, $\bar\Phi = \Phi^\dagger C$.
For the plane wave $\Phi = c\,u\,e^{i(k\cdot x - Ex_4)}$, line by line:

- $\partial_a\Phi = ik_a\Phi$ and $\partial_a\bar\Phi = -ik_a\bar\Phi$ (the
  conjugate of $e^{ik_ax_a}$ is $e^{-ik_ax_a}$);
- so $K_a = \frac12(ik_a + ik_a)\bar\Phi\gamma^{(x_a)}\Phi = ik_a|c|^2u^\dagger
  C\gamma^{(x_a)}u$, and $S = |c|^2u^\dagger Cu$;
```

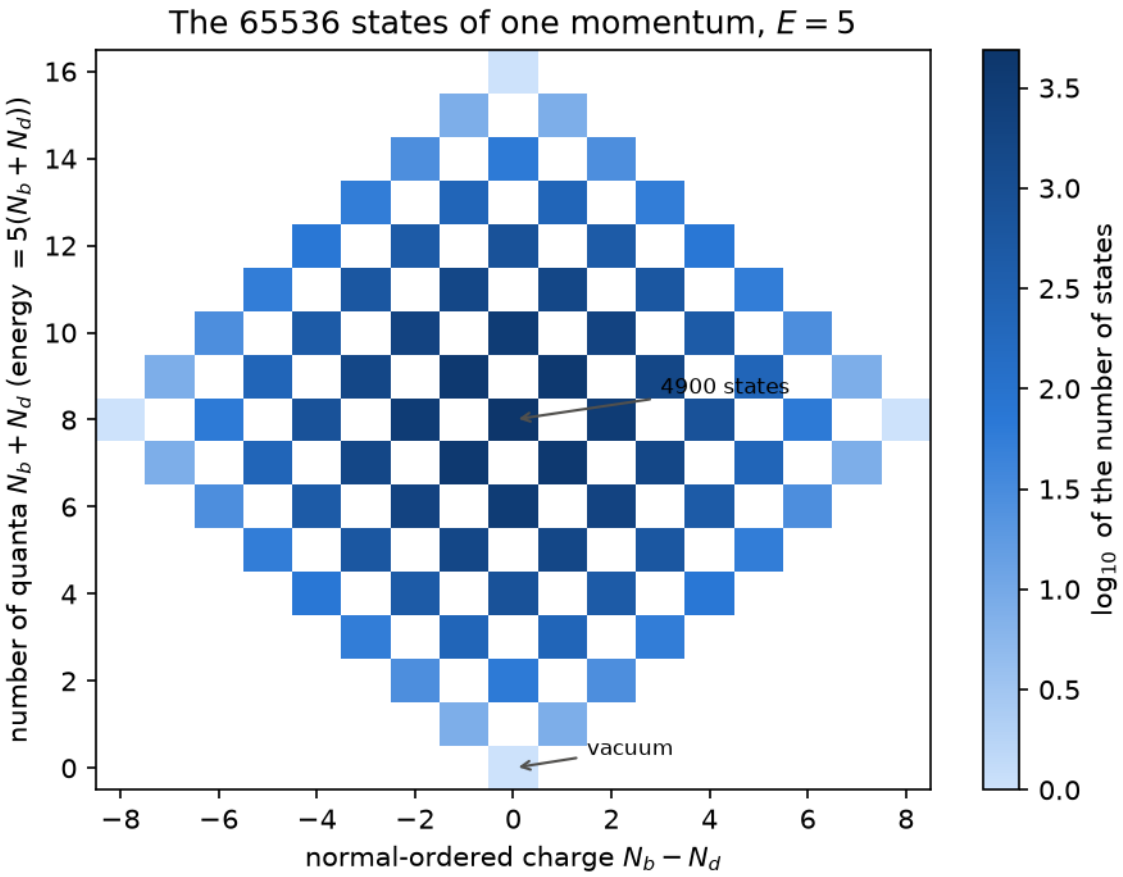

Figure 280: All $2^{16} = 65536$ quantum states of one good-sector momentum ($m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$), sorted by their normal-ordered charge $N_b - N_d$ (horizontal axis) and their number of quanta $N_b + N_d$ (vertical axis; the energy is $5(N_b + N_d)$). The colour is the base-10 logarithm of the number of states in each square (lightest blue: one state); white squares are empty. The vacuum is the single state at the bottom; there are 16 states with one quantum, and the largest number, 4900, has 8 quanta and charge 0. No state has negative energy. (Notebook 10c, figure 3.)

```
- $\rho = |c|^2u^\dagger(mC - i\sum_a k_aC\gamma^{(x_a)})u = |c|^2u^\dagger h'u$;
- since $Bh' = h$ and $B^2 = I$, $h' = Bh$, and $hu = Eu$ gives $\rho =
  E\,|c|^2\,u^\dagger Bu$.

The charge density is $\Phi^\dagger B\Phi = |c|^2u^\dagger Bu$. In the good sector
$B$ commutes with $h$, so the eigenspace of $+E$ contains 4 columns with $Bu = u$
and 4 with $Bu = -u$ (the inertia $(4, 4)$ of the first notebook). The next cell
finds them (orthonormal columns of the product of the projectors
$\frac12(I + h/E)$ and $\frac12(I \pm B)$), computes $\rho$ directly from the
formula for $K_\mu$ and $S$ (not from the shortcut), and checks the record: for
$|c| = 1$ the energy densities are $+5$ and $-5$ and the charge densities $+1$ and
$-1$.

```
The next cell compares the two fields in a bar chart, and then shows the whole range
of classical energy densities: for 4000 random unit columns $u$ in the eigenspace of
$+E$ (random combinations of its 8 orthonormal columns) the energy density
$\rho = E\,u^\dagger Bu$ of the commuting wave $\Phi = u\,e^{i(k\cdot x - Ex_4)}$.
Since $u^\dagger Bu$ lies between $-1$ and $1$, $\rho$ lies between $-5$ and $5$, and
multiplying $\Phi$ by a number $c$ multiplies $\rho$ by $|c|^2$: the energy of the
classical commuting field is unbounded below.
```

## 13. What this notebook showed

- CONSTRUCTED and CHECKED (for the two exact examples of the Revision record,
  $m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$ and $m = 3$, $k_1 = 4$, both with $E =
  5$): in the good
  sector the mode Hamiltonian is Hermitian with eigenvalues $\pm E$, the field is
  expanded in particle and antiparticle operators on a POSITIVE Fock space, and with
  $\Psi^\dagger = \chi B$ the canonical rule $\{\Psi, \Psi^\dagger\} = B$ holds.
- The vacuum, the filled Dirac sea, has energy $-8E = -40$ per momentum; after
  normal ordering every particle and every antiparticle has energy $+E$, and their
  charges are $+1$ and $-1$. All 65536 states of one momentum have non-negative
  normal-ordered energy $E(N_b + N_d)$.
- The expectation-value rule: $u^\dagger BMu$ for a particle, $-v^\dagger BMv$ for an
  antiparticle (checked for 100 random matrices and for the matrices of the
  WolframScript record).
- The classical COMMUTING field dirac16complex00 has positive-frequency waves of
  energy density $+5$ and $-5$ for the same momentum: its classical energy is
  unbounded below already for $U = 0$ in the good sector (reproduced), and its
  charge is indefinite. The quantum statements of this chapter concern only the
  fermion field dirac16complex: the author defines dirac16complex00 as a classical
  ("semi-classical") field, and the Revision record does not quantise it.
- SCOPE: the positive Fock space is built for single good-sector momenta with frozen
  coefficients (flat space). A positive-norm Hilbert space for the whole field, the
  extra-time sector with its growing waves, and the interacting operator theory
  ($\lambda \neq 0$) beyond a finite model of one good-sector mode set (in which the
  energy-momentum tensor operator obeys the on-shell identity with Wick ordering
  only) are not constructed; the next notebook shows what happens in the curved
  good sector of the author's metric without a boundary condition at $z = \pi/2$.
```

10.26 Line-by-line walk-through of Notebook 10c

The notebook has 12 code cells, In [1] to In [12]; docstrings are left out of the quotations (they are printed in Section 10.25).

In [1], the set-up cell. Its first 249 lines are comments that repeat the run instructions of Section 10.24. The code is that of In [1] of Notebook 10a (Section 10.10), with the line `NOTEBOOK_ID = "10c" # this notebook: chapter 10, example c`. It prints `Set-up of notebook 10c complete: repository folder found, helpers defined.`

In [2], the gammas, B and the mode Hamiltonian.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices

REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"

def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

The imports and the functions `record_says_pass` and `check_record` of In [2] of Notebook 10a (Section 10.10): `check_record` stops the notebook if the cited report check is missing or not PASS (the question that `record_says_pass` answers, reading each report file once into `REPORT_CHECKS`), and otherwise prints the PASS line and the line naming the reproduced record in one piece. This notebook needs no sympy.

```
BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
gamma = {a: np.array(fixture["gamma"][a], dtype=int) for a in range(8)}
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4)
```

The four colours of the figures (as in Notebook 10a), the gammas of the record `Revision/algebra/gammas.json`, C and B.

```
def mode_hamiltonian(m, k):
    h = -1j * m * gamma[4]
    for a, k_a in k.items():
        h = h - k_a * (gamma[4] @ gamma[a])
    return h
```

The mode Hamiltonian $h = -im\gamma^{(x_4)} - \gamma^{(x_4)} \sum_a k_a \gamma^{(x_a)}$ of Section 10.3, exactly as in In [5] of Notebook 10a; `k` is a dictionary of momenta.

```
def orthonormal_columns(P):
    basis = []
    for column in P.T:
        v = column.astype(complex)
        for _ in range(2):
            for e in basis:
                v = v - (e.conj() @ v) * e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:
            basis.append(v / length)
    return np.array(basis).T

say("gammas, C, B and the mode Hamiltonian are ready")
```

The Gram-Schmidt function of In [7] of Notebook 10b (Section 10.19): orthonormal columns that span the range of P. The last line prints the single output line of the cell.

In [3], the waves of one good-sector momentum.

```
def good_sector_modes(m, k):
    h = mode_hamiltonian(m, k)
    E = np.sqrt(m ** 2 + sum(k_a ** 2 for k_a in k.values()))  # no extra times
    U_plus = orthonormal_columns((np.eye(16) + h / E) / 2)
    V_minus = orthonormal_columns((np.eye(16) - h / E) / 2)
    return h, E, np.hstack([U_plus, V_minus])
```

For a good-sector momentum (only the directions 1, 2, 3, 8 in `k`) the function computes h, the energy $E = \sqrt{m^2 + \sum_a k_a^2}$, and orthonormal bases of the ranges of the projectors $\frac{1}{2}(I_{16} \pm h/E)$: the eigenvectors $u_1, \ldots, u_8$ of $+E$ and $v_1, \ldots, v_8$ of $-E$ (Section 10.20). It returns h, E and the matrix W with these 16 columns.

```
h, E, W = good_sector_modes(2, {0: 4, 1: 1, 2: 2})
report("E for m = 2, k = (4, 1, 2, 0)", f"{E:.12f}")
hermitian = np.max(np.abs(h - h.conj().T)) < 1e-15
square_ok = np.max(np.abs(h @ h - 25 * np.eye(16))) < 1e-13
commutes = np.max(np.abs(B @ h - h @ B)) < 1e-15
```

The recorded momentum $m = 2$, $k_1 = 1$, $k_2 = 2$, $k_0 = 4$ gives $E = \sqrt{4 + 1 + 4 + 16} = 5$, printed as `5.000000000000`. The three truth values test that h is Hermitian, that $hh = 25I_{16}$ and that h commutes with B.

```
eigen_ok = (np.max(np.abs(h @ W[:, :8] - E * W[:, :8])) < 1e-13
            and np.max(np.abs(h @ W[:, 8:] + E * W[:, 8:])) < 1e-13)
complete = (np.max(np.abs(W.conj().T @ W - np.eye(16))) < 1e-13
            and np.max(np.abs(W @ W.conj().T - np.eye(16))) < 1e-13)
say(f"h Hermitian: {hermitian}, h^2 = 25 I: {square_ok}, B h = h B: {commutes}")
say(f"8 + 8 eigenvectors: {eigen_ok}; orthonormal and complete: {complete}")
check(hermitian and square_ok and commutes and eigen_ok and complete
      and W.shape == (16, 16),
      "good sector: h Hermitian, h^2 = E^2, 8 + 8 orthonormal complete eigenvectors")
```

`W[:, :8]` are the first eight columns, the u_s, which must obey $hu = Eu$; `W[:, 8:]` are the last eight, the v_s, with $hv = -Ev$. `complete` tests $W^\dagger W = I_{16}$ (orthonormal) and $WW^\dagger = I_{16}$ (complete). The two printed lines show `True` for all five properties, and the check requires them and that W has 16 rows and 16 columns.

In [4], the positive Fock space and the field operators.

```
def sign_below(n, p):
    return -1 if bin(n & ((1 << p) - 1)).count("1") % 2 else 1

def annihilate(p, state):  # f_p
    result = {}
    for n, amplitude in state.items():
        if n >> p & 1:
            new = n ^ (1 << p)
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result

def create(p, state):  # f_p^*
    result = {}
    for n, amplitude in state.items():
        if not n >> p & 1:
            new = n | (1 << p)
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result
```

The Fock space of In [3] of Notebook 10b, explained line by line in Section 10.19: `sign_below` is the sign $(-1)^s$ (s the number of occupied modes below p, written here in one line), `annihilate` is f_p (it empties mode p where it is occupied) and `create` is f_p^* (it fills mode p where it is empty), both with that sign.

```
def add(*terms):
    result = {}
    for coefficient, state in terms:
        for n, amplitude in state.items():
            result[n] = result.get(n, 0) + coefficient * amplitude
    return result
```

```
def inner(left, right):
    return sum(np.conj(a) * right.get(n, 0) for n, a in left.items())

def largest(state):
    return max((abs(a) for a in state.values()), default=0.0)
```

The same three helpers as in Notebook 10b: combinations of states, the positive inner product, and the largest size of an amplitude.

```
def F(p, state):  # F_p: b (p < 8) or d^* (p >= 8)
    return annihilate(p, state) if p < 8 else create(p, state)

def F_star(p, state):  # the Hilbert adjoint of F_p
    return create(p, state) if p < 8 else annihilate(p, state)
```

The 16 modes are used as follows: modes 0 to 7 are the particles, $b_s = f_{s-1}$; modes 8 to 15 the antiparticles, $d_s = f_{s+7}$. In the field $\Psi = \sum_s (u_s b_s + v_s d_s^*)$ the particle modes enter with b and the antiparticle modes with d^*, so the field is $\Psi_A = \sum_p W_{Ap} F_p$ with $F_p = f_p$ for $p < 8$ and $F_p = f_p^*$ for $p \geq 8$. `F` is F_p, and `F_star` its Hilbert adjoint.

```
def bilinear(N, state, modes):
    M = modes.conj().T @ N @ modes
    terms = []
    for q in range(16):
        lowered = F(q, state)
        if lowered:
            terms += [(M[p, q], F_star(p, lowered)) for p in range(16)
                      if abs(M[p, q]) > 1e-15]
    return add(*terms)
```

`bilinear(N, state, modes)` applies the operator $\chi N \Psi = \sum_{A,C} \chi_A N_{AC} \Psi_C$ to a state. Inserting $\Psi_C = \sum_q W_{Cq} F_q$ and $\chi_A = \sum_p W_{Ap}^* F_p^*$ gives $\sum_{p,q} (W^\dagger N W)_{pq} F_p^* F_q$, which needs only the 16×16 matrix $\mathtt{M} = W^\dagger N W$. For each q the function applies F_q once (`lowered`); an empty dictionary counts as false, so a zero result is skipped. Then it adds $M_{pq} F_p^*$ applied to it for every p with a nonzero entry; `terms += [...]` appends the new pairs to the list.

```
def psi(A, state, modes):  # Psi_A = sum_p W_Ap F_p
    return add(*[(modes[A - 1, p], F(p, state)) for p in range(16)])

def chi(A, state, modes):  # chi_A = sum_p conj(W_Ap) F_p^*
    return add(*[(np.conj(modes[A - 1, p]), F_star(p, state)) for p in range(16)])

def psi_dagger(A, state, modes):  # the canonical conjugate: sum_C chi_C B_CA
    return add(*[(B[C_ - 1, A - 1], chi(C_, state, modes)) for C_ in range(1, 17)
                 if B[C_ - 1, A - 1] != 0])
```

The field component Ψ_A, its Hilbert adjoint χ_A and the canonical conjugate $\Psi^\dagger_A = \sum_C \chi_C B_{CA}$, as the comments say.

```
VACUUM = {0: 1.0}
rng = np.random.default_rng(12345)
phi = {int(n): complex(rng.normal(), rng.normal())
       for n in rng.integers(0, 2 ** 16, size=5)}  # a random state
```

The vacuum (every mode empty: no particle and, in this realisation, no antiparticle), a random generator with the fixed seed 12345, and a random state of 5 patterns (not normalised; the anticommutator test does not need it).

```
worst_delta, worst_B = 0.0, 0.0
for A in range(1, 17):
    for C_ in range(1, 17):

        worst_B = max(worst_B, largest(add((1, with_dagger), (-B[A - 1, C_ - 1], phi))))
report("largest violation of {Psi_A, chi_C} = delta_AC", f"{worst_delta:.1e}")
report("largest violation of {Psi_A, Psi^dagger_C} = B_AC", f"{worst_B:.1e}")
check(worst_delta < 1e-12 and worst_B < 1e-12,
      "positive Fock space: {Psi, chi} = I and {Psi, Psi^dagger} = B")
```

For all 256 pairs (A, C) the loops compute $\{\Psi_A, \chi_C\}\phi$, which must be $\delta_{AC}\phi$ (completeness, Section 10.20), and $\{\Psi_A, \Psi^\dagger_C\}\phi$, which must be $B_{AC}\phi$. Both largest deviations are printed as `6.3e-16`, rounding only, and the check prints its PASS line: on this positive Fock space the canonical rule holds.

In [5], vacuum energy, normal ordering, energies and charges.

```
def one_quantum_values(N, modes):
    vacuum_value = inner(VACUUM, bilinear(N, VACUUM, modes)).real
    values = []
    for p in range(16):  # p < 8: b^*|0>, p >= 8: d^*|0>
        state = create(p, VACUUM)
        values.append(inner(state, bilinear(N, state, modes)).real - vacuum_value)
    return np.array(values), vacuum_value
```

`one_quantum_values(N, modes)` computes the vacuum value $\langle 0|\chi N\Psi|0\rangle$ and, for each of the 16 one-quantum states (filling mode p of the vacuum gives $b^*_{p+1}|0\rangle$ for $p < 8$ and $d^*_{p-7}|0\rangle$ for $p \geq 8$), the normal-ordered value: the value in that state minus the vacuum value (Section 10.20).

```
energies, vacuum_energy = one_quantum_values(h, W)
charges, vacuum_charge = one_quantum_values(np.eye(16), W)
report("vacuum energy (the filled Dirac sea)", f"{vacuum_energy:.10f}")
report("vacuum charge before normal ordering", f"{vacuum_charge:.10f}")
say(f"normal-ordered energies of the 16 quanta: {np.round(energies, 10).tolist()}")
say(f"normal-ordered charges of the 16 quanta:  {np.round(charges, 10).tolist()}")
```

The energy is $\chi h \Psi$ ($N = h$) and the charge $\chi \Psi$ ($N = I_{16}$). The printed lines show the vacuum energy $-40.0000000000 = -8E$, the vacuum charge 8 before normal ordering, the 16 normal-ordered energies, all 5.0, and the 16 charges, eight times 1.0 and eight times -1.0: exactly the results of Section 10.20.

```
expected_charges = np.array([1] * 8 + [-1] * 8)  # 8 particles, 8 antiparticles
check_record(abs(vacuum_energy + 40) < 1e-12 and np.max(np.abs(energies - 5)) < 1e-12
             and np.max(np.abs(charges - expected_charges)) < 1e-12,
             "m = 2, k = (4, 1, 2, 0): vacuum -40, every quantum +5, charges +1, -1",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_positive_fock_realisation")
```

The check requires these numbers and reproduces the record check `good_sector_positive_fock_realisation`.

In [6], the expectation-value rule.

```
particle_points, antiparticle_points = [], []
for _ in range(100):
    M = rng.normal(size=(16, 16)) + 1j * rng.normal(size=(16, 16))
    values, _ = one_quantum_values(B @ M, W)  # real parts of <:chi B M Psi:>
    particle_points.append((values[0], (W[:, 0].conj() @ B @ M @ W[:, 0]).real))
    antiparticle_points.append((values[8], -(W[:, 8].conj() @ B @ M @ W[:, 8]).real))
particle_points = np.array(particle_points)
antiparticle_points = np.array(antiparticle_points)
```

For 100 random complex matrices M the classical bilinear $\Psi^\dagger M \Psi$ becomes the operator $\chi B M \Psi$, and `one_quantum_values(B @ M, W)` gives its normal-ordered values (real parts) in the 16 one-quantum states. The value in the first particle state ($p = 0$) is paired with the formula $u_1^\dagger B M u_1$, and the value in the first antiparticle state ($p = 8$) with $-v_1^\dagger B M v_1$ (Section 10.21).

```
worst = max(np.max(np.abs(particle_points[:, 0] - particle_points[:, 1])),
            np.max(np.abs(antiparticle_points[:, 0] - antiparticle_points[:, 1])))
report("largest deviation from the rule (100 random M)", f"{worst:.1e}")
check(worst < 1e-12,
      "rule: u^dagger B M u for a particle, -v^dagger B M v for an antiparticle")
```

The largest deviation is printed as `1.8e-15`, rounding only, and the check prints its PASS line.

```
fig, ax = plt.subplots(figsize=(6.0, 5.0))
ax.plot(particle_points[:, 1], particle_points[:, 0], "o", color=BLUE, markersize=5,
        label="particle: against $u^\\dagger B M u$")
ax.plot(antiparticle_points[:, 1], antiparticle_points[:, 0], "s", color=ORANGE,
        markersize=5, fillstyle="none",
        label="antiparticle: against $-v^\\dagger B M v$")
low = min(particle_points.min(), antiparticle_points.min()) - 1
high = max(particle_points.max(), antiparticle_points.max()) + 1
ax.plot([low, high], [low, high], color=GREY, linewidth=1)
ax.set_xlabel("value of the formula (real part)")
```

```
ax.set_ylabel("normal-ordered value on the Fock space (real part)")
ax.set_title("The expectation-value rule in the good sector")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "expectation_rule",
...)
```

The Fock-space values (vertical) are drawn against the formulas (horizontal): blue dots for particles, open orange squares for antiparticles, and the grey diagonal. Figure 1 of Notebook 10c shows all 200 points on the diagonal: the expectation-value rule of the Revision record holds in the good sector.

In [7], the second recorded example.

```
h2, E2, W2 = good_sector_modes(3, {1: 4})
energies2, vacuum2 = one_quantum_values(h2, W2)
charges2, _ = one_quantum_values(np.eye(16), W2)
dense = np.array([[(3 * A + 5 * C_) % 7 - 3 for C_ in range(1, 17)]
                  for A in range(1, 17)])
tests = {"C": C, "-i C gamma4": -1j * C @ gamma[4], "-i C gamma1": -1j * C @ gamma[1],
         "C gamma2 gamma3": C @ gamma[2] @ gamma[3], "dense": dense}
```

The momentum of the Wolfram record, $m = 3$ and $k_1 = 4$ ($E = \sqrt{9+16} = 5$), with its energies and charges. The five test matrices are those named by the record: C, $-iC\gamma^{(x_4)}$, $-iC\gamma^{(x_1)}$, $C\gamma^{(x_2)}\gamma^{(x_3)}$, and a dense matrix of whole numbers, here the notebook's own: entry (A, C) is the remainder of $3A + 5C$ after division by 7 (`%` is the remainder), minus 3.

```
rule_ok = True
for label, M in tests.items():
    values, _ = one_quantum_values(B @ M, W2)
    expected_particle = (W2[:, 0].conj() @ B @ M @ W2[:, 0]).real
    expected_anti = -(W2[:, 8].conj() @ B @ M @ W2[:, 8]).real
    rule_ok = rule_ok and abs(values[0] - expected_particle) < 1e-12 \
        and abs(values[8] - expected_anti) < 1e-12
    say(f"M = {label:16s} particle {values[0]:+.6f}, antiparticle {values[8]:+.6f}")
report("E and the vacuum energy for m = 3, k1 = 4", f"{E2:.6f} and {vacuum2:.6f}")
```

For each test matrix the loop compares the normal-ordered values with the rule (a backslash at the end of a line continues the statement on the next line) and prints one line. The printed values are $+0.6$ for $M = C$ in both states, $+1$ and -1 for $M = -iC\gamma^{(x_4)} = B$ (the charges, as Section 10.21 predicts), 0.8 for $M = -iC\gamma^{(x_1)}$, 0 for $M = C\gamma^{(x_2)}\gamma^{(x_3)}$, and -0.48 and -1.92 for the dense matrix. The RESULT line shows $E = 5$ and the vacuum energy -40.

```
check_record(abs(vacuum2 + 8 * E2) < 1e-12 and np.max(np.abs(energies2 - E2)) < 1e-12
             and np.max(np.abs(charges2 - np.array([1] * 8 + [-1] * 8))) < 1e-12
             and rule_ok,
             "m = 3, k1 = 4: vacuum -8E, energies +E, charges +-1, the rule holds",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "Fock_space_good_sector_example")
```

The check reproduces the Wolfram record check `Fock_space_good_sector_example`: vacuum $-8E$, every quantum $+E$, charges ± 1, and the rule for all five matrices.

In [8], all 65536 states of one momentum.

```
from math import comb  # comb(8, j): the number of ways to choose j of 8 things

eigen_ok = True
for n in rng.integers(0, 2 ** 16, size=200):
    n = int(n)
    n_b = bin(n & 0xFF).count("1")  # occupied particle modes (digits 0 to 7)
    n_d = bin(n >> 8).count("1")  # occupied antiparticle modes (digits 8 to 15)
    state = {n: 1.0}
```

`comb(8, j)` is the binomial coefficient $\binom{8}{j}$. For 200 random patterns: `0xFF` is the number 255 written in base 16, whose eight lowest binary digits are 1, so `n & 0xFF` keeps the digits 0 to 7 of n and their count is N_b; shifting n to the right by 8 binary places keeps the digits 8 to 15, whose count is N_d. `state` is the pattern itself with amplitude 1.

```
    energy_state = bilinear(h, state, W)
    charge_state = bilinear(np.eye(16), state, W)
    eigen_ok = eigen_ok and largest(add(
        (1, energy_state), (-(E * (n_b + n_d) - 8 * E), state))) < 1e-12
    eigen_ok = eigen_ok and largest(add(
        (1, charge_state), (-(n_b - n_d + 8), state))) < 1e-12
check(eigen_ok, "every pattern has energy E (N_b + N_d) - 8E and charge N_b - N_d + 8")
```

The energy and the charge operators are applied to the pattern, and the results are compared with the pattern times $E(N_b + N_d) - 8E$ and times $N_b - N_d + 8$ (the values before normal ordering, Section 10.20). The check confirms that every one of the 200 patterns is an eigenstate with these eigenvalues.

```
counts = np.zeros((17, 17), dtype=int)  # rows: N_b + N_d, columns: N_b - N_d + 8
for n in range(2 ** 16):
    n_b, n_d = bin(n & 0xFF).count("1"), bin(n >> 8).count("1")
    counts[n_b + n_d, n_b - n_d + 8] += 1
formula = np.zeros((17, 17), dtype=int)
for n_b in range(9):
    for n_d in range(9):
        formula[n_b + n_d, n_b - n_d + 8] += comb(8, n_b) * comb(8, n_d)
```

`counts` is a table of whole numbers: row $N_b + N_d$ (0 to 16 quanta) and column $N_b - N_d + 8$ (the charge from -8 to 8, shifted by 8 so that the column numbers start at 0). The first loop goes through all 65536 patterns and adds 1 in the square of each (`+= 1` adds to the stored value). `formula` holds the counts $\binom{8}{N_b}\binom{8}{N_d}$ of Section 10.20.

```
report("number of patterns", int(counts.sum()))
report("patterns with energy 0 (the vacuum only)", int(counts[0].sum()))
report("patterns with one quantum (energy 5)", int(counts[1].sum()))
check(np.array_equal(counts, formula) and counts.sum() == 2 ** 16,
      "the 65536 patterns are counted by binomial(8, N_b) binomial(8, N_d)")
```

The printed numbers are 65536 patterns in all, 1 with the energy 0 (the vacuum) and 16 with one quantum. The check confirms that the direct count equals the formula in every square.

In [9], the Dirac sea and the states of one momentum.

```
k_values = np.linspace(0.0, 5.0, 201)  # the size of the momentum
branch = np.sqrt(2.0 ** 2 + k_values ** 2)  # E for m = 2
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
ax = axes[0]
ax.plot(k_values, branch, color=BLUE, linewidth=2, label="$+E$: particle levels")
ax.plot(k_values, -branch, color=ORANGE, linewidth=2,
        label="$-E$: levels filled in the vacuum")
ax.fill_between(k_values, -branch, -6.5, color=ORANGE, alpha=0.2,
                label="the filled Dirac sea")
ax.set_xlabel("size of the momentum $|k|$ (with $m = 2$)")
ax.set_ylabel("eigenvalue of $h$ (classical wave energy)")
ax.set_ylim(-6.5, 6.5)
ax.set_title("classical energies of the waves")
ax.legend(loc="center right", fontsize=8)
```

The left panel draws the classical wave energies $\pm E = \pm\sqrt{4 + |k|^2}$ for $m = 2$ against the size $|k|$ of the momentum, from 0 to 5. `fill_between` shades, with 20 percent opacity (`alpha=0.2`), the region between the lower curve and the bottom of the picture: the filled sea of negative levels.

```
ax = axes[1]
ax.plot(k_values, branch, color=BLUE, linewidth=2, label="particle $b^*|0\\rangle$")
ax.plot(k_values, branch, "--", color=ORANGE, linewidth=2,
        label="antiparticle $d^*|0\\rangle$ (same curve)")
ax.axhline(0.0, color=GREY, linewidth=1)
ax.set_xlabel("size of the momentum $|k|$ (with $m = 2$)")
ax.set_ylabel("normal-ordered energy of one quantum")
ax.set_ylim(-6.5, 6.5)
ax.set_title("quantum: both quanta have energy $+E$")
ax.legend(loc="lower right", fontsize=8)
save_figure(fig, "dirac_sea",
...)
```

The right panel draws the normal-ordered energies of a particle and of an antiparticle, both $+E$, so the dashed orange curve lies on the blue one. Figure 2 of Notebook 10c shows on the left two classical branches, one of them negative and filled, and on the right only positive energies: quantisation with normal ordering turns the negative classical branch into antiparticles of positive energy.

```
from matplotlib.colors import LinearSegmentedColormap  # colour scales

fig, ax = plt.subplots(figsize=(7.0, 5.0))
shown = np.where(counts > 0, np.log10(np.maximum(counts, 1)), np.nan)  # NaN: empty
light_to_dark = LinearSegmentedColormap.from_list(
    "light_to_dark_blue", ["#cde2fb", "#2a78d6", "#0d366b"])  # 1 state is visible
image = ax.imshow(shown, origin="lower", cmap=light_to_dark, aspect="auto",
                  extent=(-8.5, 8.5, -0.5, 16.5))
```

The second figure is a heat map of the table `counts`. The colour shows the base-10 logarithm of the count (`np.log10`), so that 1 and 4900 states can both be seen; `np.maximum(counts, 1)` avoids the logarithm of 0, and `np.where` puts NaN ("not a number", drawn as white) into the empty squares. The colour scale runs from light blue (one state) to dark blue. `origin="lower"` puts row 0 at the bottom, and `extent` places the squares at the charges $-8, \ldots, 8$ horizontally and the numbers of quanta $0, \ldots, 16$ vertically.

```
ax.annotate("vacuum", (0, 0), xytext=(1.5, 0.3), fontsize=8,
            arrowprops={"arrowstyle": "->", "color": GREY})
ax.annotate("4900 states", (0, 8), xytext=(3.0, 8.6), fontsize=8,
            arrowprops={"arrowstyle": "->", "color": GREY})
ax.set_xlabel("normal-ordered charge $N_b - N_d$")
ax.set_ylabel("number of quanta $N_b + N_d$ (energy $= 5(N_b + N_d)$)")
ax.set_title("The 65536 states of one momentum, $E = 5$")
ax.grid(False)
fig.colorbar(image, ax=ax, label="$\\log_{10}$ of the number of states")
save_figure(fig, "fock_spectrum",
...)
```

Two arrows label the vacuum and the largest group, 4900 states with 8 quanta and charge 0. Figure 3 of Notebook 10c shows a diamond of filled squares: one state at the bottom (the vacuum), 16 in the row above, the largest numbers in the middle, and nothing below the vacuum: no state has negative energy.

In [10], the commuting field dirac16complex00.

```
energy_projector = (np.eye(16) + h / E) / 2  # onto the eigenspace of +E
plus_part = orthonormal_columns(energy_projector @ (np.eye(16) + B) / 2)
minus_part = orthonormal_columns(energy_projector @ (np.eye(16) - B) / 2)
k_sample = {0: 4, 1: 1, 2: 2}  # the momenta of the sample, m = 2
```

In the good sector B commutes with h, so the product of the projector onto the eigenspace of $+E$ with the projector $\frac{1}{2}(I_{16} \pm B)$ projects onto the columns that have both $hu = Eu$ and $Bu = \pm u$. Their orthonormal bases are `plus_part` and `minus_part`.

```
def energy_density(u, m=2.0, k=k_sample):
    Phibar = u.conj() @ C  # the row Phi^dagger C at x = 0
    S = (Phibar @ u).real
    K = {a: (0.5 * (Phibar @ gamma[a] @ (1j * k_a * u))
             - 0.5 * ((-1j * k_a) * Phibar) @ gamma[a] @ u) for a, k_a in k.items()}
    return (-sum(K.values()) + m * S).real
```

`energy_density(u)` computes $\rho = -\sum_a K_a + mS$ for the wave $\Phi = u\, e^{i(k\cdot x - 5x_4)}$ with $|c| = 1$, at the point $x = 0$ and the time 0, directly from the definitions of Section 10.22 and not from the shortcut $\rho = E\, u^\dagger B u$: `Phibar` is the row $\bar\Phi = \Phi^\dagger C$; $\partial_a \Phi = ik_a \Phi$ and $\partial_a \bar\Phi = -ik_a \bar\Phi$ are written as `1j * k_a * u` and `(-1j * k_a) * Phibar`, and `K` holds $K_a = \frac{1}{2}(\bar\Phi \gamma^{(x_a)} \partial_a \Phi - \partial_a \bar\Phi \gamma^{(x_a)} \Phi)$ for the three directions of the momentum.

```
densities_plus = [energy_density(plus_part[:, j]) for j in range(plus_part.shape[1])]
densities_minus = [energy_density(minus_part[:, j])
```

```
                  for j in range(minus_part.shape[1])]
charge_plus = [(u.conj() @ B @ u).real for u in plus_part.T]
charge_minus = [(u.conj() @ B @ u).real for u in minus_part.T]
say(f"dimensions: {plus_part.shape[1]} with B u = +u, {minus_part.shape[1]} with "
    f"B u = -u")
say(f"energy densities: {np.round(densities_plus, 10).tolist()} and "
    f"{np.round(densities_minus, 10).tolist()}")
say(f"charge densities: {np.round(charge_plus, 10).tolist()} and "
    f"{np.round(charge_minus, 10).tolist()}")
```

The energy densities and the charge densities $u^\dagger B u$ of the columns of both bases. The printed lines show 4 columns of each kind, the energy densities 5.0 (four times) and -5.0 (four times), and the charge densities 1.0 and -1.0.

```
check_record(plus_part.shape[1] == 4 and minus_part.shape[1] == 4
             and np.max(np.abs(np.array(densities_plus) - 5)) < 1e-12
             and np.max(np.abs(np.array(densities_minus) + 5)) < 1e-12
             and np.max(np.abs(np.array(charge_plus) - 1)) < 1e-12
             and np.max(np.abs(np.array(charge_minus) + 1)) < 1e-12,
             "commuting field: positive-frequency waves with energy +5 and -5",
             record="Revision/theory/reports/python-scope.json, check "
                    "commuting_field_energy_unbounded_below")
```

The check reproduces the record check `commuting_field_energy_unbounded_below`: waves of the same positive frequency with the energy densities $+5$ and -5.

In [11], the two fields compared.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0), sharey=True)
for ax in axes:
    ax.set_axisbelow(True)  # draw the grid lines behind the bars
classical = densities_plus + densities_minus
axes[0].bar(range(1, 9), classical,
            color=[BLUE] * len(densities_plus) + [ORANGE] * len(densities_minus))
axes[0].axhline(0.0, color=GREY, linewidth=1)
axes[0].set_xticks(range(1, 9))
axes[0].set_xlabel("positive-frequency wave (4 with $Bu = u$, 4 with $Bu = -u$)")
axes[0].set_ylabel("energy (units of $m$)")
axes[0].set_title("classical commuting field: $\\rho = \\pm 5$")
```

Two panels with a common vertical axis (`sharey=True`). The `+` of two Python lists joins them, so `classical` is the list of the eight energy densities; the left panel draws them as bars, blue for $Bu = u$ and orange for $Bu = -u$.

```
axes[1].bar(range(1, 17), energies, color=[BLUE] * 8 + [GREEN] * 8)
axes[1].axhline(0.0, color=GREY, linewidth=1)
axes[1].set_xticks(range(1, 17, 3))
axes[1].set_xlabel("quantum (1 to 8 particles, 9 to 16 antiparticles)")
axes[1].set_title("quantised fermion: every quantum $+5$")
save_figure(fig, "commuting_energy",
...)
```

The right panel draws the normal-ordered energies of the 16 one-quantum states of In [5], blue for particles and green for antiparticles. Figure 4 of Notebook 10c shows four bars of $+5$ and four of -5 on the left, and sixteen bars of $+5$ on the right: the same momentum, a positive energy for every quantum of the quantised fermion field, energies of both signs for the classical commuting field.

```
coefficients = rng.normal(size=(4000, 8)) + 1j * rng.normal(size=(4000, 8))
eigenspace = np.hstack([plus_part, minus_part])  # 8 orthonormal columns
samples = coefficients @ eigenspace.T  # each row: a random column u in the space
samples = samples / np.linalg.norm(samples, axis=1, keepdims=True)
rho = E * np.einsum("ni,ij,nj->n", samples.conj(), B, samples).real
```

4000 random complex combinations of the 8 orthonormal columns of the eigenspace of $+E$: row n of `samples` is $\sum_j c_{nj} e_j$ with the random coefficients c_{nj}, normalised to length 1. For each, `rho` is the energy density $E\,u^\dagger B u$ of Section 10.22 (the sum $u^\dagger B u$ is formed by `np.einsum`, as in In [6] of Notebook 10b).

```
report("smallest and largest energy density of the 4000 waves",
       f"{rho.min():.3f} and {rho.max():.3f}")
check(rho.min() < -2 and rho.max() > 2 and np.all(np.abs(rho) <= 5 + 1e-12),
      "random positive-frequency commuting waves have energy densities of both signs")
```

The printed range is from `-4.364` to `4.333`, inside $[-5, 5]$, and the check requires values below -2 and above 2.

```
fig, ax = plt.subplots()
ax.set_axisbelow(True)
ax.hist(rho, bins=40, range=(-5, 5), color=BLUE, edgecolor="white")
ax.axvline(0.0, color=GREY, linewidth=1)
ax.set_xlabel("energy density $\\rho = E\\,u^\\dagger B u$ of a commuting wave "
              "($|c| = 1$)")
ax.set_ylabel("number of waves (of 4000)")
ax.set_title("dirac16complex00: positive frequency, energy of both signs")
save_figure(fig, "energy_density_spread",
...)
```

A histogram with 40 bins between -5 and 5. Figure 5 of Notebook 10c shows a distribution symmetric about 0: about half of the positive-frequency waves of the commuting field have a negative energy density, and multiplying a wave by a number c multiplies its energy by $|c|^2$, so the classical energy is unbounded below.

In [12], the last check.

```
for name in ("10c_1_expectation_rule.png", "10c_2_dirac_sea.png",
             "10c_3_fock_spectrum.png", "10c_4_commuting_energy.png",
             "10c_5_energy_density_spread.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The five figure files exist, and the last line prints ALL 14 CHECKS PASSED (notebook 10c): the five figure checks and the 9 checks of the cells before (one each in In [3] to In [7], In [10] and In [11], and two in In [8]).

10.27 The curved good sector: symmetric only up to a boundary term

The positive Fock space of Section 10.20 was built for one plane wave with frozen coefficients. In the author's curved metric the waves of the good sector depend on the hidden coordinate x_0, with $z = 6Hx_0$ between the **tip** $z = 0$ and the **patch end** $z = \pi/2$, where $g_{00} = \cot^2 z$ and the volume factor $\sqrt{|g|} = \cos z$ vanish. Is the evolution there still Hermitian, and is the Krein charge still conserved?

The field equation for waves in x_4 and x_0. In the author's metric the field equation of dirac16complex with $U = 0$ is (Chapter 7, record `Revision/theory/field-theory.json`)

$$e^{-a_4}\sin^{-1/6} z\sum_{i=1}^{3}\gamma^{(x_i)}\partial_i\Psi+\gamma^{(x_4)}\partial_4\Psi+e^{a_4}\sin^{-1/6} z\sum_{t=5}^{7}\gamma^{(x_t)}\partial_t\Psi+\tan z\,\gamma^{(x_0)}\partial_0\Psi+3H\gamma^{(x_0)}\Psi=m\Psi.$$

Each derivative is divided by the scale factor of its direction ($1/f_0 = 1/\cot z = \tan z$), and $3H\gamma^{(x_0)}$ is the term $\gamma^\mu\Omega_\mu$ of the canonical spin connection (Chapter 6). For a wave of the good sector that depends only on x_4 and x_0 the first and the third sums vanish:

$$\gamma^{(x_4)}\partial_4\Psi+\tan z\,\gamma^{(x_0)}\partial_0\Psi+3H\gamma^{(x_0)}\Psi=m\Psi.$$

Multiply from the left by $\gamma^{(x_4)}$, use $\gamma^{(x_4)}\gamma^{(x_4)} = -I_{16}$, solve for $\partial_4\Psi$ (as in Section 10.3) and multiply by i:

$$i\,\partial_4\Psi = h\Psi, \qquad h = A + D\,\partial_0,$$

with the matrices

$$A=-im\gamma^{(x_4)}+3iH\gamma^{(x_4)}\gamma^{(x_0)}, \qquad D=\tan z\,M_0, \qquad M_0=i\gamma^{(x_4)}\gamma^{(x_0)}.$$

Four matrix facts. With $(\gamma^{(x_4)})^T = -\gamma^{(x_4)}$, $(\gamma^{(x_0)})^T = \gamma^{(x_0)}$ and $\gamma^{(x_0)}\gamma^{(x_4)} = -\gamma^{(x_4)}\gamma^{(x_0)}$:

(D1) $M_0^\dagger = -i(\gamma^{(x_0)})^T(\gamma^{(x_4)})^T = -i\gamma^{(x_0)}(-\gamma^{(x_4)}) = i\gamma^{(x_0)}\gamma^{(x_4)} = -i\gamma^{(x_4)}\gamma^{(x_0)} = -M_0$: M_0 is anti-Hermitian, and so is D ($\tan z$ is real).

(D2) $\cos z\, D = \cos z \tan z\, M_0 = \sin z\, M_0$.

(D3) $A^\dagger = im(\gamma^{(x_4)})^T - 3iH(\gamma^{(x_0)})^T(\gamma^{(x_4)})^T = -im\gamma^{(x_4)} + 3iH\gamma^{(x_0)}\gamma^{(x_4)} = -im\gamma^{(x_4)} - 3iH\gamma^{(x_4)}\gamma^{(x_0)}$, so $A - A^\dagger = 6iH\gamma^{(x_4)}\gamma^{(x_0)} = 6HM_0$. Since $\partial_0 \sin z = 6H\cos z$ (chain rule, $z = 6Hx_0$), this is $\cos z\,(A - A^\dagger) = (\partial_0 \sin z)\, M_0$.

(D4) B commutes with $\gamma^{(x_4)}$ and $\gamma^{(x_0)}$ (Section 10.2), hence with A, $A^\dagger$, D and M_0.

Symmetric up to a boundary term, line by line. Write u' for $\partial_0 u$, for two wave functions $u(x_0)$ and $v(x_0)$. Then

$$u^\dagger(hv) - (hu)^\dagger v = u^\dagger A v + u^\dagger D v' - u^\dagger A^\dagger v - u'^\dagger D^\dagger v = u^\dagger(A - A^\dagger)v + u^\dagger D v' + u'^\dagger D v.$$

The first step inserts $h = A + D\partial_0$ and uses $(Xw)^\dagger = w^\dagger X^\dagger$; the second collects the A terms and uses $D^\dagger = -D$ (D1). Multiply by $\cos z$ and write $G = \cos z\, D = \sin z\, M_0$ (D2):

$$\cos z\,[u^\dagger(hv) - (hu)^\dagger v] = \cos z\, u^\dagger(A - A^\dagger)v + u^\dagger G v' + u'^\dagger G v = (\partial_0 \sin z)\, u^\dagger M_0 v + \partial_0(u^\dagger G v) - u^\dagger(\partial_0 G)v.$$

The second step uses (D3) for the first term and the product rule $\partial_0(u^\dagger G v) = u'^\dagger G v + u^\dagger G' v + u^\dagger G v'$ for the other two. Since $\partial_0 G = (\partial_0 \sin z) M_0$, the first and the last terms cancel:

$$\cos z\,[u^\dagger(hv) - (hu)^\dagger v] = \partial_0\big(\sin z\; u^\dagger M_0 v\big).$$

The left side, integrated over the hidden direction with the volume $\cos z\, dx_0$, is the difference between $\int \cos z\, u^\dagger(hv)\, dx_0$ and $\int \cos z\, (hu)^\dagger v\, dx_0$; the right side is a **boundary term**: its integral over $0 < z < \pi/2$ is the bracket $\sin z\, u^\dagger M_0 v$ at $z = \pi/2$ minus its value at $z = 0$. At the tip $\sin z = 0$, so for wave functions that stay finite there the bracket vanishes. At the patch end $\sin z = 1$, and the bracket $u^\dagger M_0 v$, the **flux** through $z = \pi/2$, does not vanish in general. Example: $\gamma^{(x_4)}\gamma^{(x_0)}$ is real and symmetric ($(\gamma^{(x_4)}\gamma^{(x_0)})^T = \gamma^{(x_0)}(-\gamma^{(x_4)}) = \gamma^{(x_4)}\gamma^{(x_0)}$) and squares to $-\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_0)} = I_{16}$, so it has the eigenvalue $+1$; for a column with $\gamma^{(x_4)}\gamma^{(x_0)}u = u$ and $u^\dagger u = 2$ the flux is $u^\dagger M_0 u = i\, u^\dagger u = 2i$. The patch end is not infinitely far away: its proper distance from a point z_0 is $\int \sqrt{g_{00}}\, dx_0 = \frac{1}{6H}\int_{z_0}^{\pi/2} \cot z\, dz = -\frac{1}{6H}\ln \sin z_0$, a finite number.

The Krein version. Because B commutes with every matrix in h (D4) and is constant, $B(hu) = h(Bu)$, so $(hu)^\dagger Bv = (Bhu)^\dagger v = (h(Bu))^\dagger v$, while $u^\dagger B(hv) = (Bu)^\dagger(hv)$. The derivation above with u replaced by Bu gives

$$\cos z\,[u^\dagger B(hv) - (hu)^\dagger Bv] = \partial_0\big(\sin z\; u^\dagger B M_0 v\big).$$

The role of the spin-connection term. Without the term $3H\gamma^{(x_0)}$ the matrix A would be $A_0 = -im\gamma^{(x_4)}$ with $A_0 - A_0^\dagger = 0$, and the same steps would leave

$$\cos z\,[u^\dagger(h_0 v) - (h_0 u)^\dagger v] = \partial_0\big(\sin z\, u^\dagger M_0 v\big) - 6H\cos z\, u^\dagger M_0 v\,:$$

a remainder that is not a boundary term. In these variables and with this volume, the spin-connection term is exactly what makes the hidden-direction operator symmetric up to the boundary term. (This role depends on the variables: with $\Psi = \sin^{-1/2} z\, \chi$ the connection term disappears from the equation altogether; `python-scope.json`, check `rescaling_removes_the_connection_term`.)

What follows. The good-sector evolution in the author's metric is Hermitian, and the Krein charge $\int \cos z\, \Psi^\dagger B \Psi\, d^7x$ conserved, only if a **boundary condition** at $z = \pi/2$ removes the flux. The Kohn-Sham record imposes such a condition, the Z2 brane condition, which is ASSUMED (Chapter 14); the quantisation of the Revision record imposes none.

10.28 Waves that do not depend on x_0, and where their Krein charge goes

Finite norm. A wave of the good sector that depends on x_4 only has $\partial_0\Psi = 0$, so h acts on it as the constant matrix A. Its norm is finite: on the patch $0 < z < \pi/2$, that is $0 < x_0 < \pi/(12H)$,

$$\int_0^{\pi/(12H)} \cos(6Hx_0)\,dx_0 = \Big[\frac{\sin(6Hx_0)}{6H}\Big]_0^{\pi/(12H)} = \frac{\sin(\pi/2) - \sin 0}{6H} = \frac{1}{6H},$$

by the antiderivative of the cosine and the chain rule. So these waves are honest members of the good sector.

Growth for $m^2 < 9H^2$. Square A:

$$(-im\gamma^{(x_4)})^2 = -m^2\gamma^{(x_4)}\gamma^{(x_4)} = m^2 I_{16}, \qquad (3iH\gamma^{(x_4)}\gamma^{(x_0)})^2 = -9H^2(\gamma^{(x_4)}\gamma^{(x_0)})^2 = -9H^2 I_{16},$$

and the mixed terms cancel:

$$(-im\gamma^{(x_4)})(3iH\gamma^{(x_4)}\gamma^{(x_0)}) + (3iH\gamma^{(x_4)}\gamma^{(x_0)})(-im\gamma^{(x_4)}) = 3mH\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)} + \gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_4)}\big)$$

$$= 3mH\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)} - \gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)}\big) = 0,$$

by multiplying out ($(-i)(3i) = 3$) and by exchanging $\gamma^{(x_0)}\gamma^{(x_4)}$ in the second product. Hence

$$AA = (m^2 - 9H^2)\, I_{16}.$$

For $m^2 < 9H^2$, that is $-3H < m < 3H$, the eigenvalues of A are $\pm i\sqrt{9H^2 - m^2}$ (eight of each, because $\operatorname{tr} A = 0$), and half of these finite-norm waves grow like $e^{\kappa x_4}$ with $\kappa = \sqrt{9H^2 - m^2}$. At $m = H = 1$ the eigenvalues are $\pm\sqrt{-8} = \pm 2\sqrt{2}\,i$ (`python-scope.json`, check `good_sector_x0_independent_modes_without_boundary_condition`). For $m^2 > 9H^2$ they are real. So without a boundary condition the curved good sector of the author's metric contains growing waves whenever $|m| < 3H$.

An exact growing solution. The equation $i\,\partial_4\Psi = A\Psi$ is $\partial_4\Psi = M\Psi$ with $M = -iA = -m\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}$, and $MM = -AA = (9H^2 - m^2)I_{16} = k^2 I_{16}$ with $k = \sqrt{9H^2 - m^2}$. As in Section 10.4 the exponential series collapses (even powers $M^{2j} = k^{2j} I_{16}$, odd powers $M^{2j+1} = k^{2j} M$), and

$$\Psi(x_4) = e^{Mx_4}\chi = \Big(\cosh(kx_4)\, I_{16} + \frac{\sinh(kx_4)}{k}\, M\Big)\chi$$

for any constant column χ, by the power series of cosh and sinh. Check: $\partial_4\Psi = (k\sinh(kx_4)\, I_{16} + \cosh(kx_4)\, M)\chi$, while $M\Psi = (\cosh(kx_4)\, M + \frac{\sinh(kx_4)}{k} MM)\chi = (\cosh(kx_4)\, M + k\sinh(kx_4)\, I_{16})\chi$: equal. This is the member $\alpha = 0$ of the exact family of the Revision theory record (`python-f`

ield-theory.json, check exact_solution_family_x4_x0). For large x_4 both cosh and sinh grow like $\frac{1}{2}e^{kx_4}$, so the ordinary squared length $\Psi^\dagger\Psi$ grows like e^{2kx_4}.

Where the Krein charge goes, line by line. The Krein charge of this wave is $Q(x_4) = \int \cos z\, \Psi^\dagger B\Psi\, dx_0 = \Psi^\dagger B\Psi/(6H)$, because Ψ does not depend on x_0. Its rate of change: from $\partial_4\Psi = -ih\Psi$ and $\partial_4\Psi^\dagger = i(h\Psi)^\dagger$,

$$\partial_4(\Psi^\dagger B\Psi) = i(h\Psi)^\dagger B\Psi - i\Psi^\dagger B(h\Psi) = -i\big[\Psi^\dagger B(h\Psi) - (h\Psi)^\dagger B\Psi\big].$$

Multiply by $\cos z$, integrate over the patch, and use the Krein version of Section 10.27 with $u = v = \Psi$:

$$\frac{dQ}{dx_4} = -i\int \partial_0\big(\sin z\, \Psi^\dagger B M_0\Psi\big)\, dx_0 = -i\,\Psi^\dagger B M_0\Psi\Big|_{z=\pi/2} = \Psi^\dagger B\gamma^{(x_4)}\gamma^{(x_0)}\Psi.$$

The second step integrates the derivative (the bracket vanishes at the tip and is $\Psi^\dagger BM_0\Psi$ at $z = \pi/2$); the third inserts $M_0 = i\gamma^{(x_4)}\gamma^{(x_0)}$ and $-i\cdot i = 1$. The charge is not conserved: it changes by exactly the flux through the patch end. Notebook 10d follows it for $m = H = 1$ ($k = 2\sqrt{2}$) and a column χ with $B\chi = \chi$ and $\chi^\dagger\chi = 1$: $Q(0) = \chi^\dagger B\chi/6 = 1/6$, printed as 0.166667, and $Q(1.5) = 454.007$; the change agrees with the flux added up over time to a relative accuracy of 6.7×10^{-7}.

10.29 Example: Notebook 10d studies the curved good sector

Notebook 10d proves the four matrix facts (D1) to (D4) and the boundary-term identities of Section 10.27 exactly with sympy, checks them on two concrete wave functions, computes the flux $2i$ of the recorded column, shows the role of the spin-connection term in a figure, proves $AA = (m^2 - 9H^2)I_{16}$ and the norm $1/(6H)$, follows the eigenvalues of A as the mass grows, and verifies the exact growing solution and the change of its Krein charge by the flux through $z = \pi/2$ (Section 10.28). It draws five figures and ends with the line ALL 16 CHECKS PASSED (notebook 10d).

10.30 How to run Notebook 10d

Step 1. What this notebook does and what it needs.

Notebook 10d (The curved good sector and the boundary at z = pi/2) is the file `Revision/textbook/notebooks/10d_curved_good_sector.ipynb` of the repository Dirac_claude. In the author's metric it writes the good-sector mode operator along the hidden direction, proves exactly with sympy that it is symmetric, and that the Krein form is conserved, only up to a boundary term that vanishes at the tip z = 0 but not at the patch end z = pi/2, shows that without the spin-connection term 3 H a remainder survives, shows that the waves independent of x0 (finite norm) have the frequencies squared m^2 - 9 H^2 and therefore grow when m^2 is below 9 H^2, checks an exact growing solution and that its Krein charge changes by exactly the flux through z = pi/2, reproduces the recorded numbers, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10d_curved_good_sector.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10d_curved_good_sector.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10d_curved_good_sector.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10d.captions.json`
- `Revision/textbook/figures/10d_1_volume_and_flux.png`
- `Revision/textbook/figures/10d_2_symmetry_defect.png`
- `Revision/textbook/figures/10d_3_frequency_paths.png`
- `Revision/textbook/figures/10d_4_growth_rate.png`
- `Revision/textbook/figures/10d_5_krein_leak.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10d_5_krein_leak.png exists
ALL 16 CHECKS PASSED (notebook 10d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10d_curved_good_sector.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10d_curved_good_sector.ipynb
python -m nbconvert --execute --inplace 10d_curved_good_sector.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.31 Notebook 10d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10d_curved_good_sector.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The previous notebooks of this chapter worked with plane waves in flat 4+4 space (or
with the coefficients frozen at one point). This notebook goes back to the author's
curved metric and looks at the good sector (no dependence on the extra times
$x_5, x_6, x_7$) along the hidden direction $x_0$, with $z = 6Hx_0$ running from
the tip $z = 0$ to the patch end $z = \pi/2$. It

- writes the mode operator $h$ of the field equation for waves that depend only on
  $x_4$ and $x_0$: $i\,\partial_4\Psi = h\Psi$;
- proves exactly (sympy) that $h$ is symmetric for the volume $\cos z\,dx_0$ only up
  to a boundary term $\partial_0(\sin z\,u^\dagger M_0v)$, and that the Krein form is
  conserved only up to a similar term; the term vanishes at the tip but NOT at
  $z = \pi/2$;
- shows that the spin-connection term $3H\gamma^{(x_0)}$ of the field equation is
  exactly what makes the hidden-direction operator symmetric up to that boundary
  term (without it a remainder $-6H\cos z\,u^\dagger M_0v$ survives);
- shows that the waves that do not depend on $x_0$ (they have a finite norm) see the
  matrix $A = -im\gamma^{(x_4)} + 3iH\gamma^{(x_4)}\gamma^{(x_0)}$, with $A^2 = (m^2 -
  9H^2)I_{16}$: for $m^2 < 9H^2$ their frequencies are imaginary and they grow;
- checks an exact growing solution, and that its Krein charge changes in time by
  exactly the flux through $z = \pi/2$;
- reproduces the recorded numbers and draws five teaching figures.

The message for the chapter: the positive Fock space of the previous notebook is a
```

```
construction for flat space (frozen coefficients). In the curved good sector the
evolution is Hermitian, and the Krein charge conserved, only if a boundary condition
is imposed at $z = \pi/2$, and the Revision record imposes none.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 10d (The curved good sector and the boundary at z = pi/2) is the file
‘Revision/textbook/notebooks/10d_curved_good_sector.ipynb‘ of the repository
Dirac_claude. In the author’s metric it writes the good-sector mode operator along the
hidden direction, proves exactly with sympy that it is symmetric, and that the Krein form
is conserved, only up to a boundary term that vanishes at the tip z = 0 but not at the
patch end z = pi/2, shows that without the spin-connection term 3 H a remainder survives,
shows that the waves independent of x0 (finite norm) have the frequencies squared m^2 - 9
H^2 and therefore grow when m^2 is below 9 H^2, checks an exact growing solution and that
its Krein charge changes by exactly the flux through z = pi/2, reproduces the recorded
numbers, and draws five teaching figures. It needs a computer with Windows 11, macOS or
Linux, an internet connection for the installation, the program Git, and Python 3.12 or
newer (the notebooks were built with Python 3.14.5) with these packages at exactly these
versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10,
nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook
itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program
that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 10d_curved_good_sector.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical

laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10d_curved_good_sector.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10d_curved_good_sector.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10d.captions.json‘
- ‘Revision/textbook/figures/10d_1_volume_and_flux.png‘
- ‘Revision/textbook/figures/10d_2_symmetry_defect.png‘
- ‘Revision/textbook/figures/10d_3_frequency_paths.png‘
- ‘Revision/textbook/figures/10d_4_growth_rate.png‘
- ‘Revision/textbook/figures/10d_5_krein_leak.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10d_5_krein_leak.png exists
ALL 16 CHECKS PASSED (notebook 10d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started

without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10d_curved_good_sector.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 10d_curved_good_sector.ipynb
python -m nbconvert --execute --inplace 10d_curved_good_sector.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 10d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10d (The curved good sector and the boundary at z = pi/2) is the file
# Revision/textbook/notebooks/10d_curved_good_sector.ipynb of the repository
# Dirac_claude. In the author's metric it writes the good-sector mode operator along the
# hidden direction, proves exactly with sympy that it is symmetric, and that the Krein
# form is conserved, only up to a boundary term that vanishes at the tip z = 0 but not at
# the patch end z = pi/2, shows that without the spin-connection term 3 H a remainder
# survives, shows that the waves independent of x0 (finite norm) have the frequencies
# squared m^2 - 9 H^2 and therefore grow when m^2 is below 9 H^2, checks an exact growing
# solution and that its Krein charge changes by exactly the flux through z = pi/2,
# reproduces the recorded numbers, and draws five teaching figures. It needs a computer
# with Windows 11, macOS or Linux, an internet connection for the installation, the
# program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
```

```
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
```

```
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10d_curved_good_sector.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10d_curved_good_sector.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
```

```
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10d_curved_good_sector.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10d.captions.json
# - Revision/textbook/figures/10d_1_volume_and_flux.png
# - Revision/textbook/figures/10d_2_symmetry_defect.png
# - Revision/textbook/figures/10d_3_frequency_paths.png
# - Revision/textbook/figures/10d_4_growth_rate.png
# - Revision/textbook/figures/10d_5_krein_leak.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10d_5_krein_leak.png exists
#     ALL 16 CHECKS PASSED (notebook 10d)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10d_curved_good_sector.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
```

```
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10d_curved_good_sector.ipynb
#     python -m nbconvert --execute --inplace 10d_curved_good_sector.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.

## 3. The words used in this notebook

- **Hidden direction, $z$, tip, patch end**: $x_0$ is the hidden space direction;
```

  $z = 6Hx_0$ runs over $0 < z < \pi/2$. The *tip* is $z \to 0$, the *patch end* is $z = \pi/2$, where the author's metric component $g_{00} = \cot^2 z$ and the volume factor $\sqrt{|g|} = \cos z$ vanish.
- **Volume element**: $\sqrt{|g|} = \cos z$; an integral over the hidden direction is $\int \cos z\,(\ldots)\,dx_0$.
- **Symmetric operator (formally Hermitian)**: an operator h with $\int\cos z\,u^\dagger(hv)\,dx_0 = \int\cos z\,(hu)^\dagger v\,dx_0$ for all wave functions u, v. A *boundary term* is a part of the integrand that is a derivative, $\partial_0(\ldots)$; its integral is the difference of the bracket at the two ends, so the operator is symmetric when that difference vanishes.
- **Krein form, Krein charge**: $\int\cos z\,u^\dagger Bv\,dx_0$; for $u = v = \Psi$ it is the charge of the wave.
- **Flux**: the value of the bracket at an end; a nonzero flux at $z = \pi/2$ means that something flows through the patch end (in or out).
- **Boundary condition**: a rule imposed on the wave functions at an end (for example that a flux vanishes there); it is an assumption added to the equations.
- **M_0**: the matrix $i\gamma^{(x_4)}\gamma^{(x_0)}$.
- **Exponential of a matrix**: $e^{Mx_4} = \sum_n (Mx_4)^n/n!$; if $M^2 = k^2 I$ the series collapses to $\cosh(kx_4)I + \frac{\sinh(kx_4)}{k}M$ (even and odd powers).

Text cell:

```
## 4. The physical and mathematical situation

**The field equation for waves in $x_4$ and $x_0$ only.** The field equation of
dirac16complex in the author's metric (Revision theory record, $U = 0$) is

$$e^{-a_4}\sin^{-1/6}z\sum_{i=1}^3\gamma^{(x_i)}\partial_i\Psi + \gamma^{(x_4)}
\partial_4\Psi + e^{a_4}\sin^{-1/6}z\sum_{t=5}^7\gamma^{(x_t)}\partial_t\Psi +
\tan z\,\gamma^{(x_0)}\partial_0\Psi + 3H\gamma^{(x_0)}\Psi = m\Psi .$$

For a wave that depends only on $x_4$ and $x_0$ the first and third groups vanish:

$$\gamma^{(x_4)}\partial_4\Psi + \tan z\,\gamma^{(x_0)}\partial_0\Psi +
3H\gamma^{(x_0)}\Psi = m\Psi .$$

Multiply from the left by $\gamma^{(x_4)}$, use $(\gamma^{(x_4)})^2 = -1$ and solve
for $\partial_4\Psi$:

$$\partial_4\Psi = -m\gamma^{(x_4)}\Psi + \tan z\,\gamma^{(x_4)}\gamma^{(x_0)}
\partial_0\Psi + 3H\gamma^{(x_4)}\gamma^{(x_0)}\Psi .$$

Multiply by $i$:

$$i\,\partial_4\Psi = h\Psi,\qquad h = A + D\,\partial_0,\qquad
A = -im\gamma^{(x_4)} + 3iH\gamma^{(x_4)}\gamma^{(x_0)},\qquad D = \tan z\,M_0,
\qquad M_0 = i\gamma^{(x_4)}\gamma^{(x_0)} .$$

**Symmetry up to a boundary term, line by line.** Write $u'$ for $\partial_0u$. Then

$$u^\dagger(hv) - (hu)^\dagger v = u^\dagger(A - A^\dagger)v + u^\dagger Dv' -
u'^\dagger D^\dagger v .$$
```

```
The notebook checks that $M_0$ is anti-Hermitian, so $D^\dagger = -D$ ($\tan z$ is
real), and the last two terms are $u^\dagger Dv' + u'^\dagger Dv =
(u^\dagger Dv)' - u^\dagger D'v$ (product rule). Multiply by $\cos z$. The notebook
checks the two matrix identities $\cos z\,D = \sin z\,M_0$ and
$\cos z\,(A - A^\dagger) = (\sin z)'M_0$; with them (and the product rule
$(\cos z\,D)' = (\cos z)'D + \cos z\,D'$) everything collects into one derivative:

$$\cos z\,\big[u^\dagger(hv) - (hu)^\dagger v\big] = \partial_0\big(\sin z\;
u^\dagger M_0 v\big).$$

Integrated over $0 < z < \pi/2$ this is $[\sin z\,u^\dagger M_0v]$ at $z = \pi/2$
minus its value at $z = 0$. At the tip $\sin z = 0$; at the patch end $\sin z = 1$,
so the flux $u^\dagger M_0v$ there does not vanish in general. The term
$3iH\gamma^{(x_4)}\gamma^{(x_0)}$ of $A$ (the spin-connection term $3H\gamma^{(x_0)}$
of the field equation) supplies exactly $A - A^\dagger = 6HM_0$, which is needed
because $(\sin z)' = 6H\cos z$.

**Waves that do not depend on $x_0$.** For them $\partial_0\Psi = 0$ and $h$ acts as
the constant matrix $A$. Their norm $\int_0^{\pi/(12H)}\cos(6Hx_0)\,dx_0 = 1/(6H)$ is
finite (the patch $0 < z < \pi/2$ is $0 < x_0 < \pi/(12H)$), so they are honest
members of the good sector. The notebook proves $A^2 = (m^2 - 9H^2)I_{16}$: for
$m^2 < 9H^2$, that is $-3H < m < 3H$, the frequencies are imaginary and these waves
grow. (The pictures below take $m \geq 0$; the mass enters only through $m^2$.)
```

Text cell:

```
## 5. The matrices of the hidden direction

The next cell reads the gammas, builds $C$ and $B$ with numpy and as exact sympy
matrices, defines the symbols $m$, $H$ (positive) and $x_0$, the expression
$z = 6Hx_0$, and the matrices $M_0$, $A$ and $D$ of Section 4. It also defines
‘check_record‘ (the PASS line and the line of the reproduced Revision record are
printed in one piece, so that the stored output is the same in every run; before
that it confirms with the helper ‘record_says_pass‘ that the cited report check
still exists with the verdict PASS) and the colours. Then it checks the matrix
facts of Section 4 exactly: $M_0^\dagger = -M_0$, $\cos z\,D = \sin z\,M_0$ and
$\cos z\,(A - A^\dagger) = \partial_0(\sin z)\,M_0$, and in addition that $B$
commutes with $\gamma^{(x_4)}$ and $\gamma^{(x_0)}$. The last fact gives the Krein
version: $B$ then commutes with $A$, $A^\dagger$, $D$ and $M_0$, so the same steps
with $u^\dagger B$ in place of $u^\dagger$ give $\cos z\,[u^\dagger B(hv) -
(hu)^\dagger Bv] = \partial_0(\sin z\,u^\dagger BM_0v)$.

## 6. Symmetric up to a boundary term, checked on wave functions

The matrix identities prove the statement of Section 4 for all wave functions. The
next cell also checks it directly on two concrete wave functions $u(x_0)$ and
$v(x_0)$: each of their 16 entries is a combination $a + b\sin z + c\cos z$ with
small whole numbers $a, b, c$ (real and imaginary parts chosen at random with a
fixed seed). It computes, exactly,

- the defect $\cos z\,[u^\dagger(hv) - (hu)^\dagger v] - \partial_0(\sin z\,u^\dagger
  M_0v)$, which must be 0;
- the same with the operator WITHOUT the spin-connection term, which must equal
  $-6H\cos z\,u^\dagger M_0v$ instead;
- the Krein version $\cos z\,[u^\dagger B(hv) - (hu)^\dagger Bv] - \partial_0(\sin z
  \,u^\dagger BM_0v)$, which must be 0.

To let sympy recognise the zeros, $x_0$ is replaced by $z/(6H)$ and the
trigonometric functions are expanded before simplifying.
```

```
## 7. The flux at the two ends

The bracket $\sin z\,u^\dagger M_0v$ vanishes at the tip ($\sin 0 = 0$) for wave
functions that stay finite there, but at the patch end $z = \pi/2$ it is
$u^\dagger M_0v$. The Revision record gives an example: the matrix
$\gamma^{(x_4)}\gamma^{(x_0)}$ is real, symmetric and squares to $I$, so it has the
eigenvalue $+1$; for a column with $\gamma^{(x_4)}\gamma^{(x_0)}u = u$ and
$u^\dagger u = 2$ the flux is $u^\dagger M_0u = i\,u^\dagger u = 2i$, not 0. The next
cell builds such a column ($u = e_A + \gamma^{(x_4)}\gamma^{(x_0)}e_A$ for the first
unit column $e_A$) and draws the volume factor $\cos z$ and the flux factor
$\sin z$ along the hidden direction.
```

In [4]:

```
G40 = gamma[4] @ gamma[0]  # gamma^(x4) gamma^(x0), real

Text cell:

```
The next cell makes the role of the spin-connection term visible for one pair of
wave functions, here $u = v$ (the test function $u$ of Section 6) at $m = H = 1$:
it evaluates along $0 < z < \pi/2$ the left-hand side $\cos z\,[u^\dagger(hu) -
(hu)^\dagger u]$, the right-hand side $\partial_0(\sin z\,u^\dagger M_0u)$, and the
left-hand side computed WITHOUT the term $3H$. For $u = v$ all three are purely
imaginary (a number minus its complex conjugate), so their imaginary parts are
plotted. The exact expressions are turned into fast numerical functions with
‘sp.lambdify‘.

## 8. Waves that do not depend on $x_0$: growth for $m^2 < 9H^2$

For a wave that depends on $x_4$ only, $h$ acts as the constant matrix $A$. The next
cell checks exactly: the norm integral $\int_0^{\pi/(12H)}\cos(6Hx_0)\,dx_0 =
1/(6H)$ is finite; $A$ is not Hermitian; $A^2 = (m^2 - 9H^2)I_{16}$ (the same
cancellation of mixed terms as for the mode Hamiltonian of flat space, because
$\gamma^{(x_4)}$ and $\gamma^{(x_4)}\gamma^{(x_0)}$ anticommute); and at $m = H = 1$
the eigenvalues are $\pm 2\sqrt2\,i$, eight of each (the trace of $A$ is 0).
```

In [6]:

## 9. An exact growing solution, and where its Krein charge goes

For a wave of $x_4$ alone the equation $i\partial_4\Psi = A\Psi$ reads
$\partial_4\Psi = M\Psi$ with $M = -iA = -m\gamma^{(x_4)} + 3H\gamma^{(x_4)}
\gamma^{(x_0)}$, and $M^2 = (9H^2 - m^2)I = k^2I$. Its solution is $\Psi(x_4) =
e^{Mx_4}\chi = \big(\cosh(kx_4)I + \frac{\sinh(kx_4)}{k}M\big)\chi$ for any constant
column $\chi$: the case $\alpha = 0$ of the exact family of the Revision theory
record. The next cell checks exactly that it solves the full field equation of
Section 4 (with $\partial_0\Psi = 0$).

Then it follows, for $m = H = 1$ ($k = 2\sqrt2$) and a column $\chi$ with
$B\chi = \chi$, the ordinary squared length $\Psi^\dagger\Psi$ and the Krein charge
$Q(x_4) = \int\cos z\,\Psi^\dagger B\Psi\,dx_0 = \Psi^\dagger B\Psi/(6H)$. By
Section 6 (with $u = v = \Psi$ and $\partial_0\Psi = 0$) the charge changes at the
rate of the flux through the patch end:
$dQ/dx_4 = -i\,[\sin z\,\Psi^\dagger BM_0\Psi]_{z = \pi/2} =
\Psi^\dagger B\gamma^{(x_4)}\gamma^{(x_0)}\Psi$. The cell checks that $Q(x_4) - Q(0)$
equals the flux added up over time (trapezoidal sums on a fine grid).

            "/k\\,M)\\chi$, independent of $x_0$, for $m = H = 1$ ($k = 2\\sqrt{2}$) "
            "and a column $\\chi$ with $B\\chi = \\chi$; horizontal axes: the time "
            "$x_4$ in units of $1/H$. Left: the logarithm of its squared length "
            "grows with the slope $2k$ (grey dashed line). Right: its Krein charge "
            "$Q = \\int\\cos z\\,\\Psi^\\dagger B\\Psi\\,dx_0$ (orange) is not "
            "constant; it equals its starting value plus the flux through the "
            "patch end $z = \\pi/2$ added up over time (green dashed). Without a "
            "boundary condition at $z = \\pi/2$ the Krein charge is not conserved: "
            "it changes by exactly what passes through the patch end.")
```

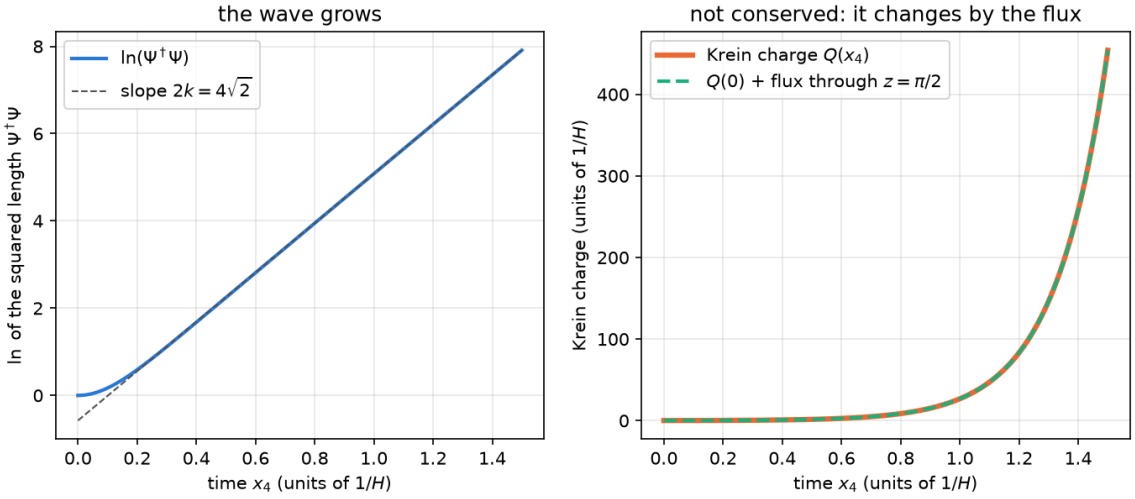

Figure 287: The exact good-sector solution $\Psi(x_4) = (\cosh kx_4 + \sinh(kx_4)/k\,M)\chi$, independent of x_0, for $m = H = 1$ ($k = 2\sqrt{2}$) and a column χ with $B\chi = \chi$; horizontal axes: the time x_4 in units of $1/H$. Left: the logarithm of its squared length grows with the slope $2k$ (grey dashed line). Right: its Krein charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, dx_0$ (orange) is not constant; it equals its starting value plus the flux through the patch end $z = \pi/2$ added up over time (green dashed). Without a boundary condition at $z = \pi/2$ the Krein charge is not conserved: it changes by exactly what passes through the patch end. (Notebook 10d, figure 5.)

```
## 11. What this notebook showed

- PROVED (exactly): in the author's metric the good-sector mode operator along the
  hidden direction, $h = -im\gamma^{(x_4)} + 3iH\gamma^{(x_4)}\gamma^{(x_0)} +
  i\tan z\,\gamma^{(x_4)}\gamma^{(x_0)}\partial_0$, satisfies $\cos z\,[u^\dagger(hv)
  - (hu)^\dagger v] = \partial_0(\sin z\,u^\dagger M_0v)$: it is symmetric for the
  volume $\cos z\,dx_0$ only up to a boundary term, which vanishes at the tip but
  not at the patch end $z = \pi/2$ (flux $2i$ for the recorded column). The Krein
  form is conserved up to the analogous term.
- PROVED: the spin-connection term $3H\gamma^{(x_0)}$ is what makes the defect a pure
  boundary term in these variables and this volume; without it the remainder
  $-6H\cos z\,u^\dagger M_0v$ survives. (In other variables, $\Psi = \sin^{-1/2}z\,
  \chi$ with the volume $dy$, no such term is needed: this role of $3H$ depends on
  the variables, as the Revision record states.)
- PROVED: the good-sector waves that do not depend on $x_0$ have a finite norm and
  the frequencies $\pm\sqrt{m^2 - 9H^2}$; for $m^2 < 9H^2$ they grow (at
  $m = H = 1$ the eigenvalues are $\pm 2\sqrt2\,i$). The exact solution of the
  record with $\alpha = 0$ is such a wave.
- COMPUTED: for that solution the Krein charge is not conserved; it changes by
  exactly the flux through $z = \pi/2$.
- CONSEQUENCE (the scope of the quantisation in the Revision record): Hermiticity of
  the curved good-sector evolution and conservation of the Krein charge need a
  boundary condition at $z = \pi/2$ (for example the ASSUMED brane condition of the
  Kohn-Sham record); the Revision quantisation imposes none. The positive Fock space
  of the previous notebook is built for single good-sector momenta with frozen
  coefficients; a positive Hilbert space for the whole field is not constructed.
```

10.32 Line-by-line walk-through of Notebook 10d

The notebook has 10 code cells, In [1] to In [10]; docstrings are left out of the quotations (they are printed in Section 10.31).

In [1], the set-up cell. Its first 248 lines are comments that repeat the run instructions of Section 10.30. The code is that of In [1] of Notebook 10a (Section 10.10), with the line `NOTEBOOK_ID = "10d" # this notebook: chapter 10, example d`. It prints `Set-up of notebook 10d complete: repository folder found, helpers defined.`

In [2], the matrices of the hidden direction.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices
import sympy as sp  # exact algebra with symbols

REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"

def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

The imports and the helpers `REPORT_CHECKS`, `record_says_pass` and `check_record` of In [2] of Notebook 10a (Section 10.10): a cited report check must still exist with the verdict PASS, and the PASS line and the line naming the record are printed in one piece.

```
BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
gamma = {a: np.array(fixture["gamma"][a], dtype=float) for a in range(8)}
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4)
g = {a: sp.Matrix(fixture["gamma"][a]) for a in range(8)}  # exact gammas
B_exact = -sp.I * g[0] * g[1] * g[2] * g[3] * g[4]
```

The colours; the gammas as numpy arrays of decimal numbers (`dtype=float`, because they will be combined with decimal numbers such as the mass 1.0), C and B; and the same gammas and B as exact sympy matrices.

```
m = sp.Symbol("m", real=True)  # the mass
H = sp.Symbol("H", positive=True)  # the author's constant H > 0
x0 = sp.Symbol("x0", real=True)  # the hidden coordinate
z = 6 * H * x0  # z = 6 H x0
M0 = sp.I * g[4] * g[0]  # M_0 = i gamma^(x4) gamma^(x0)
A = -sp.I * m * g[4] + 3 * sp.I * H * g[4] * g[0]  # the part without derivative
A_no_connection = -sp.I * m * g[4]  # the same without the term 3 H
D = sp.tan(z) * M0  # the coefficient of the derivative d/dx0
zero = sp.zeros(16, 16)
```

The letters m (any real number), H (positive) and x_0, and the expression $z = 6Hx_0$. Then the matrices of Section 10.27: $M_0 = i\gamma^{(x_4)}\gamma^{(x_0)}$, $A = -im\gamma^{(x_4)} + 3iH\gamma^{(x_4)}\gamma^{(x_0)}$, the matrix $A_0 = -im\gamma^{(x_4)}$ without the spin-connection term, and $D = \tan z\, M_0$; `zero` is the 16×16 zero matrix.

```
anti_hermitian = M0.H == -M0
identity_D = (sp.cos(z) * D - sp.sin(z) * M0).applyfunc(sp.simplify) == zero
identity_A = (sp.cos(z) * (A - A.H) - sp.diff(sp.sin(z), x0) * M0).applyfunc(
    sp.simplify) == zero
B_commutes = (B_exact * g[4] == g[4] * B_exact) and (B_exact * g[0] == g[0] * B_exact)
```

The four matrix facts: (D1) $M_0^\dagger = -M_0$ (`.H` is the conjugate transpose); (D2) $\cos z\, D - \sin z\, M_0 = 0$, every entry simplified; (D3) $\cos z\,(A - A^\dagger) - (\partial_0 \sin z) M_0 = 0$, where `sp.diff(sp.sin(z), x0)` is the derivative $6H\cos z$; (D4) B commutes with $\gamma^{(x_4)}$ and with $\gamma^{(x_0)}$.

```
say(f"M0 anti-Hermitian: {anti_hermitian}; cos z D = sin z M0: {identity_D}; "
    f"cos z (A - A^dagger) = d0(sin z) M0: {identity_A}; B commutes with "
    f"gamma^(x4) and gamma^(x0): {B_commutes}")
check(anti_hermitian and identity_D and identity_A and B_commutes,
      "exact: the four matrix identities of the hidden direction")
```

The printed line shows `True` four times, and the check prints its PASS line.

In [3], symmetric up to a boundary term, on wave functions.

```
rng = np.random.default_rng(12345)

def test_function():
    def number():
        return int(rng.integers(-3, 4)) + sp.I * int(rng.integers(-3, 4))
    return sp.Matrix([number() + number() * sp.sin(z) + number() * sp.cos(z)
                      for _ in range(16)])
```

A random generator with the fixed seed 12345. `test_function` builds a column of 16 exact functions of x_0, each of the form $a + b\sin z + c\cos z$. The inner function `number` returns a complex whole number whose real and imaginary parts are drawn from -3 to 3 (`rng.integers(-3, 4)` excludes the upper end 4).

```
def apply_h(matrix_A, w):
    return matrix_A * w + D * w.diff(x0)
```

```
def is_zero(expression):
    zz = sp.Symbol("zz")
    rewritten = sp.expand_trig(sp.expand(expression.subs(x0, zz / (6 * H))))
    return sp.simplify(rewritten) == 0
```

`apply_h(matrix_A, w)` applies the operator $h = A + D\partial_0$ (or h_0 when the matrix A_0 is given) to a column w of functions; `w.diff(x0)` differentiates every entry. `is_zero` decides exactly whether an expression vanishes: it writes $x_0 = zz/(6H)$ with a new letter zz, so that z becomes zz and H drops out of the trigonometric functions, multiplies out, expands the trigonometric functions of sums (`sp.expand_trig`), and simplifies.

```
u, v = test_function(), test_function()
hv, hu = apply_h(A, v), apply_h(A, u)
defect = (sp.cos(z) * ((u.H * hv)[0] - (hu.H * v)[0])
          - sp.diff(sp.sin(z) * (u.H * M0 * v)[0], x0))
```

Two test functions u and v, and hv, hu. `u.H * hv` is the row $u^\dagger$ times the column hv, a 1×1 matrix, and `[0]` takes its single entry. `defect` is $\cos z\,[u^\dagger(hv) - (hu)^\dagger v] - \partial_0(\sin z\, u^\dagger M_0 v)$, which must vanish (Section 10.27).

```
hv0, hu0 = apply_h(A_no_connection, v), apply_h(A_no_connection, u)
defect_without = (sp.cos(z) * ((u.H * hv0)[0] - (hu0.H * v)[0])
                  - sp.diff(sp.sin(z) * (u.H * M0 * v)[0], x0))
remainder_ok = is_zero(defect_without + 6 * H * sp.cos(z) * (u.H * M0 * v)[0])
krein_defect = (sp.cos(z) * ((u.H * B_exact * hv)[0] - (hu.H * B_exact * v)[0])
                - sp.diff(sp.sin(z) * (u.H * B_exact * M0 * v)[0], x0))
```

The variable `defect_without` is the same defect for the operator without the spin-connection term. By Section 10.27 it must equal $-6H\cos z\, u^\dagger M_0 v$, so `remainder_ok` tests that it plus $6H\cos z\, u^\dagger M_0 v$ vanishes. The variable `krein_defect` is the Krein version, with $u^\dagger B$ in place of $u^\dagger$.

```
check_record(is_zero(defect),
             "exact: cos z (u^dagger h v - (h u)^dagger v) = d0(sin z u^dagger M0 v)",
             record="Revision/theory/reports/python-scope.json, check "
                    "good_sector_hermiticity_up_to_the_brane_flux")
check_record(remainder_ok,
             "exact: without the term 3 H the remainder -6 H cos z u^dagger M0 v stays",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "good_sector_hermiticity_curved")
check_record(is_zero(krein_defect),
             "exact: the Krein form is conserved up to d0(sin z u^dagger B M0 v)",
             record="Revision/theory/reports/wolfram-field-theory.json, check "
                    "Krein_form_conserved_curved")
```

Three exact checks, reproducing the record checks `good_sector_hermiticity_up_to_the_brane_flux`, `good_sector_hermiticity_curved` and `Krein_form_conserved_curved`.

In [4], the flux at the two ends.

```
G40 = gamma[4] @ gamma[0]  # gamma^(x4) gamma^(x0), real
symmetric_square = np.array_equal(G40, G40.T) and np.array_equal(G40 @ G40,
                                                                 np.eye(16))
e_first = np.eye(16)[:, 0]
u_flux = e_first + G40 @ e_first  # an eigenvector of G40 with eigenvalue +1
M0_numbers = 1j * G40
flux_value = u_flux.conj() @ M0_numbers @ u_flux
```

`G48` is $\gamma^{(x_4)}\gamma^{(x_0)}$; `symmetric_square` tests that it is symmetric and squares to I_{16} (Section 10.27). `e_first` is the first unit column e_1 (the first column of the identity matrix), and `u_flux` $= e_1 + \gamma^{(x_4)}\gamma^{(x_0)}e_1$ is an eigenvector with eigenvalue $+1$: applying $\gamma^{(x_4)}\gamma^{(x_0)}$ gives $\gamma^{(x_4)}\gamma^{(x_0)}e_1 + e_1$, the same column, because the matrix squares to I_{16}. `flux_value` is $u^\dagger M_0 u$.

```
report("u^dagger u for the column u = e_1 + gamma4 gamma0 e_1", f"{u_flux @ u_flux:.1f}")
report("flux u^dagger M0 u at z = pi/2",
       f"{flux_value.imag:.1f} i (real part {abs(flux_value.real):.1f})")
check_record(symmetric_square and np.allclose(G40 @ u_flux, u_flux)
             and abs(flux_value - 2j) < 1e-14,
             "the flux at z = pi/2 is u^dagger M0 u = 2 i for gamma4 gamma0 u = u",
             record="Revision/theory/reports/python-scope.json, check "
                    "good_sector_hermiticity_up_to_the_brane_flux")
```

The printed lines show $u^\dagger u = 2.0$ and the flux $2.0\,i$ with real part 0.0 (the size of the real part is printed, so that no minus sign of a rounding zero appears). The check reproduces the record's example.

```
z_values = np.linspace(0.0, np.pi / 2, 400)
fig, ax = plt.subplots()
ax.plot(z_values, np.cos(z_values), color=BLUE, linewidth=2,
        label="volume factor $\\sqrt{|g|} = \\cos z$")
ax.plot(z_values, np.sin(z_values), color=ORANGE, linewidth=2,
        label="flux factor $\\sin z$ of the bracket")
ax.plot([0.0], [0.0], "o", color=ORANGE, markersize=8)
ax.plot([np.pi / 2], [1.0], "o", color=ORANGE, markersize=8)
```

400 values of z from 0 to $\pi/2$; the blue curve is the volume factor $\cos z$, the orange curve the factor $\sin z$ of the boundary bracket, with dots at its two ends.

```
ax.annotate("tip: the flux vanishes", (0.0, 0.0), xytext=(0.15, 0.25),
            arrowprops={"arrowstyle": "->", "color": GREY})
ax.annotate("patch end: the flux remains", (np.pi / 2, 1.0), xytext=(0.55, 1.08),
            arrowprops={"arrowstyle": "->", "color": GREY})
ax.set_xlabel("$z = 6 H x_0$ (from the tip $z = 0$ to the patch end $z = \\pi/2$)")
ax.set_ylabel("value")
ax.set_ylim(-0.05, 1.25)
ax.set_title("The hidden direction: volume and boundary flux")
ax.legend(loc="center left")
save_figure(fig, "volume_and_flux",
...)
```

Two arrows explain the two dots. Figure 1 of Notebook 10d shows the volume falling from 1 to 0 and the bracket factor rising from 0 to 1: the volume vanishes at the patch end, but the boundary bracket does not, so a flux can pass through $z = \pi/2$.

In [5], the role of the spin-connection term in a picture.

```
numbers = {m: 1, H: 1}  # m = H = 1, so z = 6 x0
hu_full, hu_bare = apply_h(A, u), apply_h(A_no_connection, u)
left = sp.cos(z) * ((u.H * hu_full)[0] - (hu_full.H * u)[0])
right = sp.diff(sp.sin(z) * (u.H * M0 * u)[0], x0)
left_bare = sp.cos(z) * ((u.H * hu_bare)[0] - (hu_bare.H * u)[0])
```

For $u = v$ and $m = H = 1$ the cell forms the three exact expressions: the defect with the term $3H$ (`left`), the derivative $\partial_0(\sin z\, u^\dagger M_0 u)$ (`right`) and the defect without the term (`left_bare`).

```
x0_values = np.linspace(0.002, np.pi / 12 - 0.002, 300)  # inside 0 < z < pi/2
curves = [np.imag(sp.lambdify(x0, e.subs(numbers), "numpy")(x0_values))
          for e in (left, right, left_bare)]
difference = np.max(np.abs(curves[0] - curves[1]))
report("largest |left - right| on the grid", f"{difference:.1e}")
check(difference < 1e-9, "numerical: the two sides agree along the hidden direction")
```

For $H = 1$ the patch is $0 < x_0 < \pi/12$; the 300 points stay a little inside it. `e.subs(numbers)` puts $m = H = 1$ into an expression, and `sp.lambdify(x0, ..., "numpy")` turns it into a fast numpy function of x_0, which is evaluated at all points at once. For $u = v$ each expression is a number minus its complex conjugate, purely imaginary, so `np.imag` keeps the imaginary parts. The largest difference between the left and the right side is printed as `5.7e-13`, rounding only.

```
fig, ax = plt.subplots()
ax.plot(6 * x0_values, curves[0], color=BLUE, linewidth=3,
        label="left side, with the term $3H$")
ax.plot(6 * x0_values, curves[1], "--", color=GREEN, linewidth=2,
        label="right side $\\partial_0(\\sin z\\,u^\\dagger M_0 u)$")
ax.plot(6 * x0_values, curves[2], color=ORANGE, linewidth=2,
        label="left side WITHOUT the term $3H$")
ax.set_xlabel("$z = 6 H x_0$ ($m = H = 1$)")
ax.set_ylabel("imaginary part")
ax.set_title("The spin-connection term makes the defect a pure boundary term")
ax.legend(fontsize=8)
save_figure(fig, "symmetry_defect",
...)
```

The three curves against $z = 6x_0$. Figure 2 of Notebook 10d shows the green dashed curve exactly on the thick blue one, and the orange curve away from both: with the spin-connection term the defect is a derivative, whose integral is the flux at the ends; without it the remainder $-6H\cos z\, u^\dagger M_0 u$ of Section 10.27 separates the curves.

In [6], the waves that do not depend on x_0.

```
norm_integral = sp.integrate(sp.cos(6 * H * x0), (x0, 0, sp.pi / (12 * H)))
say(f"integral of cos(6 H x0) over the patch: {norm_integral}")
A_square_ok = (A * A - (m ** 2 - 9 * H ** 2) * sp.eye(16)).applyfunc(
    sp.expand) == zero
A_not_hermitian = (A - A.H).applyfunc(sp.expand) != zero
G40_numbers = gamma[4] @ gamma[0]  # gamma^(x4) gamma^(x0) as numbers
```

`sp.integrate(f, (x0, a, b))` computes the definite integral exactly; the printed value is `1/(6*H)`, the norm of Section 10.28. The two truth values test $AA = (m^2 - 9H^2)I_{16}$ and that A is not Hermitian ($A - A^\dagger$ is not the zero matrix). `G48_numbers` is $\gamma^{(x_4)}\gamma^{(x_0)}$ again, for the numerical part.

```
def A_numbers_of(mass, H_value=1.0):
    return -1j * mass * gamma[4] + 3j * H_value * G40_numbers

A_numbers = A_numbers_of(1.0)
eigenvalues = np.linalg.eigvals(A_numbers)
upper = int(np.sum(np.abs(eigenvalues - 2j * np.sqrt(2)) < 1e-9))
lower = int(np.sum(np.abs(eigenvalues + 2j * np.sqrt(2)) < 1e-9))
report("eigenvalues 2 sqrt(2) i and -2 sqrt(2) i at m = H = 1, how many",
       f"{upper} and {lower}")
```

`A_numbers_of(mass)` is the matrix A as numbers for a given mass ($H = 1$ unless another value is given). At $m = H = 1$ the 16 eigenvalues are counted: how many lie within 10^{-9} of $2\sqrt{2}\,i$ and how many of $-2\sqrt{2}\,i$. The printed counts are 8 and 8.

```
check_record(norm_integral == 1 / (6 * H) and A_square_ok and A_not_hermitian
             and (upper, lower) == (8, 8),
             "x0-independent waves: A^2 = (m^2 - 9 H^2) I, at m = H = 1: +-2 sqrt(2) i",
             record="Revision/theory/reports/python-scope.json, check "
                    "good_sector_x0_independent_modes_without_boundary_condition")
```

The check reproduces the record check `good_sector_x0_independent_modes_without_boundary_condition`.

In [7], the frequencies against the mass.

```
mass_values = np.linspace(0.0, 5.0, 101)
paths = []
for mass in mass_values:
    paths.append(np.linalg.eigvals(A_numbers_of(mass)))
paths = np.array(paths)
worst = np.max(np.abs(np.sort(np.abs(paths), axis=1)
                      - np.sqrt(np.abs(mass_values ** 2 - 9))[:, None]))
report("largest deviation of |eigenvalue| from sqrt|m^2 - 9|", f"{worst:.1e}")
check(worst < 1e-6, "the eigenvalues of A follow +-sqrt(m^2 - 9 H^2)")
```

For 101 masses from 0 to 5 (step 0.05) the 16 eigenvalues of A are stored as one row of the table `paths`. Every eigenvalue must have the size $\sqrt{|m^2 - 9|}$ ($H = 1$): `np.abs(paths)` are the sizes,

sorted in each row, and `[:, None]` turns the 101 predicted values into a column, so that each is subtracted from its own row. The largest deviation is printed as `4.6e-08`: at $m = 3$ exactly the matrix A has $AA = 0$ and cannot be diagonalised, and there the numerical eigenvalues are accurate only to about 10^{-8}; the tolerance 10^{-6} allows for it.

```
fig, ax = plt.subplots(figsize=(6.0, 5.0))
growing = mass_values < 3.0
for column in range(16):
    ax.plot(paths[growing, column].real, paths[growing, column].imag, ".",
            color=ORANGE, markersize=4)
    ax.plot(paths[~growing, column].real, paths[~growing, column].imag, ".",
            color=BLUE, markersize=4)
ax.plot([], [], ".", color=ORANGE, label="$m < 3H$: imaginary, the waves grow")
ax.plot([], [], ".", color=BLUE, label="$m > 3H$: real, the waves oscillate")
ax.plot([0, 0], [2 * np.sqrt(2), -2 * np.sqrt(2)], "o", color=GREEN, markersize=9,
        fillstyle="none", label="recorded: $m = H = 1$, $\\pm 2\\sqrt{2}\\,i$")
```

`growing` is a list of truth values, true for the masses below 3; `paths[growing, column]` picks the eigenvalue number `column` at those masses, and `~growing` is the opposite list. Each eigenvalue is drawn as a dot in the complex plane (real part horizontal, imaginary part vertical), orange for $m < 3$ and blue for $m \geq 3$; the empty plots only create legend entries; green circles mark the recorded values $\pm 2\sqrt{2}\,i$.

```
ax.set_xlabel("real part of the eigenvalue of $A$ (units of $H$)")
ax.set_ylabel("imaginary part (units of $H$)")
ax.set_aspect("equal")
ax.set_title("Frequencies of the $x_0$-independent waves, $m$ from 0 to 5")
ax.legend(loc="upper left", bbox_to_anchor=(1.02, 1.0), fontsize=8)  # outside
save_figure(fig, "frequency_paths",
...)
```

Equal scales on both axes; `bbox_to_anchor` places the legend outside the drawing, to its right. Figure 3 of Notebook 10d shows the eigenvalues coming down the imaginary axis from $\pm 3i$ (at $m = 0$) to 0 (at $m = 3$) and then moving out along the real axis: growth for $m < 3H$, oscillation for $m > 3H$.

```
rate = np.sqrt(np.maximum(9.0 - mass_values ** 2, 0.0))
fig, ax = plt.subplots()
ax.plot(mass_values, rate, color=ORANGE, linewidth=2,
        label="growth rate $\\kappa = \\sqrt{9H^2 - m^2}$")
ax.plot([1.0], [2 * np.sqrt(2)], "o", color=GREEN, markersize=9,
        label="recorded: $m = H = 1$, $\\kappa = 2\\sqrt{2}$")
ax.axvline(3.0, color=GREY, linestyle=":", linewidth=1)
ax.set_xlabel("mass $m$ in units of $H$")
ax.set_ylabel("growth rate $\\kappa$ (units of $H$)")
ax.set_title("Without a boundary condition: growth for $m < 3H$")
ax.legend()
save_figure(fig, "growth_rate",
...)
```

The growth rate $\kappa = \sqrt{9 - m^2}$ for $m < 3$ and 0 beyond (`np.maximum(..., 0.0)` replaces the negative values under the root by 0), with the recorded point $\kappa = 2\sqrt{2} \approx 2.83$ at $m = 1$. Figure 4 of Notebook 10d shows the curve falling from 3 at $m = 0$ to 0 at $m = 3$ (a quarter of the circle $\kappa^2 + m^2 = 9$, drawn with unequal scales on the two axes): without a boundary condition at $z = \pi/2$, every mass below $3H$ gives growing waves of finite norm.

In [8], the exact growing solution and its Krein charge.

```
x4, k = sp.symbols("x4 k", positive=True)
M_exact = -m * g[4] + 3 * H * g[4] * g[0]
chi = sp.Matrix(sp.symbols("q1:17"))  # any constant column
Psi = (sp.cosh(k * x4) * sp.eye(16) + sp.sinh(k * x4) / k * M_exact) * chi
field_equation = g[4] * Psi.diff(x4) + 3 * H * g[0] * Psi - m * Psi  # d0 Psi = 0
```

`sp.symbols("x4 k", positive=True)` makes two positive letters at once, and `sp.symbols("q1:17")` the 16 letters $q_1, \ldots, q_{16}$, the entries of an arbitrary constant column χ. `M_exact` is $M = -m\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}$ and `Psi` the solution of Section 10.28. `field_equation` is the left side minus the right side of the field equation of Section 10.27 for a wave with $\partial_0 \Psi = 0$, which must vanish.

```
# multiply by k, then replace k^2 by 9 H^2 - m^2 (the definition of k)
residual = field_equation.applyfunc(
    lambda e: sp.expand(sp.expand(k * e).subs(k ** 2, 9 * H ** 2 - m ** 2)))
square_ok = (M_exact * M_exact - (9 * H ** 2 - m ** 2) * sp.eye(16)).applyfunc(
    sp.expand) == zero
check_record(square_ok and residual == sp.zeros(16, 1),
             "exact: Psi = (cosh kx4 + sinh(kx4)/k M) chi solves the field equation",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "exact_solution_family_x4_x0")
```

The expression contains $1/k$ (from $\sinh(kx_4)/k$); as the comment says, every entry is multiplied by k to clear it, multiplied out, and every k^2 is replaced by $9H^2 - m^2$, the definition of k; then every entry must be 0. `square_ok` checks $MM = (9H^2 - m^2)I_{16}$. The check reproduces the record check `exact_solution_family_x4_x0`.

```
M_numbers = -1.0 * gamma[4] + 3.0 * G40  # m = H = 1
k_number = np.sqrt(8.0)  # k = sqrt(9 - 1) = 2 sqrt(2)
plus_columns = (np.eye(16) + B) / 2  # columns with B chi = chi (after scaling)
chi_number = plus_columns[:, 0] / np.linalg.norm(plus_columns[:, 0])
x4_values = np.linspace(0.0, 1.5, 3001)
lengths, charges, fluxes = [], [], []
```

For $m = H = 1$: M as numbers and $k = \sqrt{9 - 1} = 2\sqrt{2}$. The columns of the projector $\frac{1}{2}(I_{16} + B)$ lie in the eigenspace $B\chi = \chi$; its first column, divided by its length, is the starting column χ with $\chi^\dagger \chi = 1$. 3001 times from 0 to 1.5 (step 0.0005).

```
for t in x4_values:
    Psi_t = (np.cosh(k_number * t) * np.eye(16)
```

```
            + np.sinh(k_number * t) / k_number * M_numbers) @ chi_number
    lengths.append((Psi_t.conj() @ Psi_t).real)
    charges.append((Psi_t.conj() @ B @ Psi_t).real / 6.0)  # 6 H = 6
    fluxes.append((Psi_t.conj() @ B @ G40 @ Psi_t).real)
lengths, charges, fluxes = map(np.array, (lengths, charges, fluxes))
```

At each time the loop computes $\Psi(x_4)$, its ordinary squared length $\Psi^\dagger\Psi$, its Krein charge $Q = \Psi^\dagger B\Psi/(6H)$ and the flux $\Psi^\dagger B\gamma^{(x_4)}\gamma^{(x_0)}\Psi$, the rate dQ/dx_4 of Section 10.28. `map(np.array, ...)` turns each of the three lists into an array.

```
step = x4_values[1] - x4_values[0]
added_flux = np.concatenate([[0.0], np.cumsum((fluxes[1:] + fluxes[:-1]) / 2) * step])
relative = np.max(np.abs(charges - charges[0] - added_flux)) / np.max(np.abs(charges))
report("Krein charge Q at x4 = 0 and at x4 = 1.5", f"{charges[0]:.6f} and "
       f"{charges[-1]:.3f}")
report("largest relative mismatch of Q(x4) - Q(0) and the added flux",
       f"{relative:.1e}")
check(relative < 1e-5, "the Krein charge changes by the flux through z = pi/2")
```

The flux is added up over time by the **trapezoidal rule**: on each step the area under the curve is the step times the mean of the two end values, `(fluxes[1:] + fluxes[:-1]) / 2` (`fluxes[1:]` drops the first value and `fluxes[:-1]` the last); `np.cumsum` forms the running sums, and a 0 is put in front for the time 0. The mismatch between $Q(x_4) - Q(0)$ and the added flux, divided by the largest charge, is printed as `6.7e-07`; the RESULT lines show $Q(0) = 0.166667 = 1/6$ and $Q(1.5) = 454.007$. The check confirms that the charge changes by the flux through the patch end.

```
growth = np.polyfit(x4_values[1500:], np.log(lengths[1500:]), 1)[0]
report("late slope of ln(Psi^dagger Psi)", f"{growth:.4f} (2 k = {2 * k_number:.4f})")
check(abs(growth - 2 * k_number) < 0.05, "the squared length grows like exp(2 k x4)")
```

`np.polyfit(x, y, 1)` fits the straight line $y = ax + b$ through the points by least squares and returns (a, b); `[0]` takes the slope. The fit uses the second half of the times (from index 1500, $x_4 = 0.75$, on) and the logarithm of the squared length $\Psi^\dagger\Psi$ (the list `lengths` holds these squared lengths). The printed slope is 5.6600, close to $2k = 5.6569$ (the squared length contains cosh and sinh, not a pure exponential, so the slope only approaches $2k$), and the check allows a difference of 0.05. The cell prints three PASS lines.

In [9], the growing wave and its charge in a picture.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
axes[0].plot(x4_values, np.log(lengths), color=BLUE, linewidth=2,
             label="$\\ln(\\Psi^\\dagger\\Psi)$")
axes[0].plot(x4_values, 2 * k_number * x4_values + np.log(lengths[-1])
             - 2 * k_number * x4_values[-1], "--", color=GREY, linewidth=1,
             label="slope $2k = 4\\sqrt{2}$")
axes[0].set_xlabel("time $x_4$ (units of $1/H$)")
axes[0].set_ylabel("$\\ln$ of the squared length $\\Psi^\\dagger\\Psi$")
axes[0].set_title("the wave grows")
axes[0].legend()
```

The left panel draws $\ln(\Psi^\dagger\Psi)$ against x_4 and a grey dashed straight line of slope $2k = 4\sqrt{2}$ through the last point.

```
axes[1].plot(x4_values, charges, color=ORANGE, linewidth=3,
             label="Krein charge $Q(x_4)$")
axes[1].plot(x4_values, charges[0] + added_flux, "--", color=GREEN, linewidth=2,
             label="$Q(0)$ + flux through $z = \\pi/2$")
axes[1].set_xlabel("time $x_4$ (units of $1/H$)")
axes[1].set_ylabel("Krein charge (units of $1/H$)")
axes[1].set_title("not conserved: it changes by the flux")
axes[1].legend()
save_figure(fig, "krein_leak",
...)
```

The right panel draws the Krein charge and its starting value plus the added flux. Figure 5 of Notebook 10d shows the logarithm of the squared length rising along a straight line, and the charge rising from 1/6 to several hundred, with the green dashed curve exactly on the orange one: without a boundary condition at $z = \pi/2$ the Krein charge of the curved good sector is not conserved; it changes by exactly what passes through the patch end.

In [10], the last check.

```
for name in ("10d_1_volume_and_flux.png", "10d_2_symmetry_defect.png",
             "10d_3_frequency_paths.png", "10d_4_growth_rate.png",
             "10d_5_krein_leak.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The five figure files exist, and the last line prints ALL 16 CHECKS PASSED (notebook 10d): the five figure checks and the 11 checks of the cells before (1 in In [2], 3 in In [3], 1 each in In [4] to In [7], and 3 in In [8]).

10.33 No invariant charge density is positive

The charge density $\Psi^\dagger B\Psi$ takes both signs. Could a cleverer choice of the charge density avoid this? A charge density must not depend on how the frame of the eight directions is turned, so it must be built from a form that is unchanged by the spin transformations. This section shows that every such density is indefinite.

Spin transformations and invariant forms. The 28 **generators** $S^{ab} = \frac{1}{4}[\gamma^{(x_a)}, \gamma^{(x_b)}] = \frac{1}{2}\gamma^{(x_a)}\gamma^{(x_b)}$ ($a < b$; the second form uses $\gamma^{(x_b)}\gamma^{(x_a)} = -\gamma^{(x_a)}\gamma^{(x_b)}$) generate the spin transformations $R = \exp(\theta S^{ab})$, which turn the frame, and their products form Spin(4,4) (Chapter 5). A **bilinear form** $\Psi^T G\Phi$ with a 16×16 matrix G is **invariant** if it does not change when both columns are transformed by the same R: $R^T GR = G$. For $R = I_{16} + \theta S$ with a small number θ,

$$R^T GR = G + \theta\,(S^T G + GS) + \theta^2 S^T GS,$$

by multiplying out; the form is unchanged to first order in θ exactly when

$$S^T G + GS = 0 \quad \text{for all 28 generators.}$$

The gammas are real, so $S^\dagger = S^T$, and the same condition makes the Hermitian form $\Psi^\dagger G \Psi$ invariant.

All invariant forms. Chapter 5 showed two facts. First, $C\gamma^{(x_a)}C = -(\gamma^{(x_a)})^T$ (the charge-conjugation property of $C = \mathcal{C}_+$; `wolfram-algebra.json`, check `C_gamma_C_inverse`). Hence

$$(S^{ab})^T = \tfrac{1}{2}(\gamma^{(x_b)})^T(\gamma^{(x_a)})^T = \tfrac{1}{2}(C\gamma^{(x_b)}C)(C\gamma^{(x_a)}C) = \tfrac{1}{2}C\gamma^{(x_b)}\gamma^{(x_a)}C = -CS^{ab}C,$$

by the transpose of a product, the property of C (the two minus signs cancel), $CC = I_{16}$, and $\gamma^{(x_b)}\gamma^{(x_a)} = -\gamma^{(x_a)}\gamma^{(x_b)}$. Insert it into the condition and multiply from the left by C:

$$S^T G + GS = 0 \iff -CSCG + GS = 0 \iff -SCG + CGS = 0 \iff (CG)S = S(CG).$$

So G is invariant exactly when CG commutes with all 28 generators. Second, the matrices that commute with all generators of Spin(4,4) form a two-dimensional family, spanned by the chiral projectors $P_- = \frac{1}{2}(I_{16} - \Gamma)$ and $P_+ = \frac{1}{2}(I_{16} + \Gamma)$ (the commutant of Spin(4,4) has dimension 2; `python-algebra.json`, check `spin_commutant_dimension_2`; `wolfram-algebra.json`, check `Spin44_commutant_dim_2_chiral_projectors`). Hence $CG = r_- P_- + r_+ P_+$, and, multiplying by C,

$$G = r_-\, CP_- + r_+\, CP_+.$$

Every invariant form is a combination of CP_- and CP_+; the choice $r_- = r_+ = 1$ gives $G = C$ and the Spin(4,4) scalar $\bar{\Psi}\Psi = \Psi^\dagger C \Psi$ (`wolfram-algebra.json`, check `S_preserves_C`).

Every invariant charge density is indefinite. A charge density is the time component of a current, so it is built from an invariant form and the time gamma: its matrix is the Hermitian part $X = \frac{1}{2}(Y + Y^\dagger)$ of $Y = cG\gamma^{(x_4)}$ with a complex number c (the Hermitian part makes the density $\Psi^\dagger X \Psi$ real). Now C is a product of four gammas, so it commutes with Γ (moving Γ through four gammas costs $(-1)^4 = +1$), and $P_\mp$ commute with Γ; so G commutes with Γ, while $\gamma^{(x_4)}$ anticommutes with it. With $\Gamma\Gamma = I_{16}$:

$$\Gamma Y \Gamma = cG\,\Gamma\gamma^{(x_4)}\Gamma = -cG\gamma^{(x_4)} = -Y, \qquad \Gamma X \Gamma = \tfrac{1}{2}\big(\Gamma Y\Gamma + (\Gamma Y\Gamma)^\dagger\big) = -X,$$

where the second identity uses that Γ is Hermitian, so $\Gamma Y^\dagger \Gamma = (\Gamma Y \Gamma)^\dagger$. Multiply $\Gamma X \Gamma = -X$ from the left by Γ: $X\Gamma = -\Gamma X$. If $Xv = \lambda v$, then

$$X(\Gamma v) = -\Gamma X v = -\lambda\, \Gamma v :$$

Γ carries every eigenvector of X with eigenvalue λ to one with eigenvalue $-\lambda$, and back. So the eigenvalues of X come in pairs $\lambda, -\lambda$ of equal multiplicity, and the density $\Psi^\dagger X \Psi$ takes both signs

unless $X = 0$. The canonical choice $c = -i$, $G = C$ gives $Y = -iC\gamma^{(x_4)} = B$, which is already Hermitian, so $X = B$ with eigenvalues ± 1, eight each. **In signature (4,4) no invariant charge density is positive**: the indefinite charge of dirac16complex is not an accident of the choice B. (In ordinary 3+1 dimensions the time gamma also anticommutes with the chirality γ_5, so that fact alone is not the difference. The difference is the invariant form. In 3+1 dimensions it is $G = \gamma^0$, a single gamma, which anticommutes with γ_5; so the density matrix $G\gamma^0 = \gamma^0\gamma^0 = I_4$ commutes with γ_5, the argument above gives no pairing, and the density $\psi^\dagger\psi$ is positive. In (4,4) the invariant forms $r_- CP_- + r_+ CP_+$ are built from C, a product of four gammas, and commute with Γ, while $\gamma^{(x_4)}$ anticommutes with it; this is what produces the pairing $\lambda \to -\lambda$.)

10.34 The symmetries that keep the canonical rule

A transformation $\Psi \to R\Psi$ keeps the canonical anticommutator exactly when $RBR^\dagger = B$ (Section 10.15). This is equivalent to $R^\dagger BR = B$: multiplying $RBR^\dagger = B$ from the left by R^{-1} and from the right by $(R^\dagger)^{-1}$ gives $B = R^{-1}B(R^\dagger)^{-1}$; the inverse of both sides, with $B^{-1} = B$, is $B = R^\dagger BR$. We call such an R **Krein-unitary**. An R with $R^\dagger R = I_{16}$ keeps the ordinary length and is **unitary**.

The conditions on a generator. For $R = I_{16} + \theta S$ to first order, $R^\dagger R = I_{16} + \theta(S^\dagger + S)$ and $R^\dagger BR = B + \theta(S^\dagger B + BS)$, so the conditions are

$$\text{unitary: } S^\dagger = -S, \qquad \text{Krein-unitary: } S^\dagger B + BS = 0.$$

The first order suffices for all θ: if $S^\dagger B = -BS$, then $(S^\dagger)^n B = B(-S)^n$ by moving B through one factor at a time, so $\exp(\theta S^\dagger)B = B\exp(-\theta S)$ (term by term in the power series) and $R^\dagger BR = B\exp(-\theta S)\exp(\theta S) = B$.

Which generators are anti-Hermitian. For $a \neq b$, with $(\gamma^{(x_a)})^\dagger = \eta_{aa}\gamma^{(x_a)}$ (Section 10.15),

$$(\gamma^{(x_a)}\gamma^{(x_b)})^\dagger = (\gamma^{(x_b)})^\dagger(\gamma^{(x_a)})^\dagger = \eta_{aa}\eta_{bb}\,\gamma^{(x_b)}\gamma^{(x_a)} = -\eta_{aa}\eta_{bb}\,\gamma^{(x_a)}\gamma^{(x_b)}.$$

So S^{ab} is anti-Hermitian when $\eta_{aa}\eta_{bb} = +1$ (both directions space-like or both time-like: a **rotation**), and Hermitian when $\eta_{aa}\eta_{bb} = -1$ (one space-like and one time-like: a **boost**). The space-like directions are x_0, x_1, x_2, x_3 and the time-like ones x_4, x_5, x_6, x_7, so there are $6 + 6 = 12$ rotations (pairs within each group of four, $\binom{4}{2} = 6$) and $4 \times 4 = 16$ boosts.

Which generators commute with B. $\gamma^{(x_a)}B = s_a B\gamma^{(x_a)}$ with $s_a = +1$ for $a = 1, 2, 3, 4, 8$ and -1 for $a = 5, 6, 7$ (Section 10.2), so $\gamma^{(x_a)}\gamma^{(x_b)}B = s_a s_b\, B\gamma^{(x_a)}\gamma^{(x_b)}$: S^{ab} commutes with B when $s_a s_b = +1$, that is both in $\{1, 2, 3, 4, 8\}$ ($\binom{5}{2} = 10$ pairs) or both in $\{5, 6, 7\}$ (3 pairs), 13 in all, and anticommutes otherwise ($5 \times 3 = 15$ pairs).

The Krein condition. For an anti-Hermitian S the condition $S^\dagger B + BS = 0$ reads $BS - SB = 0$: S must commute with B. For a Hermitian S it reads $SB + BS = 0$: S must anticommute with B. Counting:

- rotations that commute with B: the 6 among x_0, x_1, x_2, x_3 and the 3 among x_5, x_6, x_7; the 3 rotations $S^{(x_4 x_t)}$, $t = 5, 6, 7$, anticommute and fail;
- boosts that anticommute with B: one direction among x_0, x_1, x_2, x_3 and one among x_5, x_6, x_7, $4 \times 3 = 12$; the 4 boosts $S^{(x_a x_4)}$, $a = 1, 2, 3, 8$, commute and fail.

So exactly $9+12=21$ generators are Krein-unitary: precisely the $\binom{7}{2}=21$ pairs that do not contain x_4. They generate **Spin(4,3)**, the spin group of the seven slice directions (four space-like, three time-like). For the 7 generators with x_4 written first, $S^{(x_4x_b)}=\frac{1}{2}\gamma^{(x_4)}\gamma^{(x_b)}$, the condition fails by $S^\dagger B+BS=2BS=-iC\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_b)}=iC\gamma^{(x_b)}$ (in both cases the left side equals $2BS$, because either $S^\dagger=S$ and $SB=BS$, or $S^\dagger=-S$ and $SB=-BS$; then $\gamma^{(x_4)}\gamma^{(x_4)}=-I_{16}$). Of the 21, the 9 rotations are also unitary; the 12 boosts mixing a space direction with an extra time keep the canonical rule but change the ordinary squared length (and so the length). The canonical structure singles out the time x_4, as $\psi^\dagger\psi$ does in ordinary Dirac theory: a transformation that turns x_4 into another direction also changes the slices $x_4=\text{const}$ on which the field is quantised.

Finite rotations and boosts. For $a\neq b$, $(\gamma^{(x_a)}\gamma^{(x_b)})^2=-\gamma^{(x_a)}\gamma^{(x_a)}\gamma^{(x_b)}\gamma^{(x_b)}=-\eta_{aa}\eta_{bb}I_{16}$, so $(S^{ab})^2=-\frac{1}{4}\eta_{aa}\eta_{bb}I_{16}$. As in Section 10.4 the exponential series collapses:

$$\exp(\theta S^{ab})=\cos\tfrac{\theta}{2}\,I_{16}+2\sin\tfrac{\theta}{2}\,S^{ab}\ \text{(rotation)},\qquad \exp(\theta S^{ab})=\cosh\tfrac{\theta}{2}\,I_{16}+2\sinh\tfrac{\theta}{2}\,S^{ab}\ \text{(boost)}.$$

(For a rotation write $S=\frac{1}{2}J$ with $JJ=-I_{16}$; the even powers of θS give the cosine series of $\theta/2$ and the odd ones J times the sine series. For a boost $JJ=+I_{16}$ and the hyperbolic functions appear.) Example: a column u with $Bu=u$ and $u^\dagger u=1$, boosted by $S^{(x_1x_5)}$ (Hermitian, Krein-unitary). Since R is Hermitian, $R^\dagger R=RR=\exp(2\theta S)=\cosh\theta\,I_{16}+2\sinh\theta\,S$, and $u^\dagger Su=0$ (because S anticommutes with B: $u^\dagger Su=u^\dagger SBu=-u^\dagger BSu=-(Bu)^\dagger Su=-u^\dagger Su$); so the ordinary squared length $(Ru)^\dagger(Ru)=u^\dagger R^\dagger Ru$ becomes $\cosh\theta$, while the Krein norm stays 1.

10.35 Example: Notebook 10e computes the invariant forms and the generators

Notebook 10e builds the 28 generators, solves the 28×256 linear equations $S^T G + GS = 0$ numerically and checks the two solutions $CP_{\mp}$ exactly (Section 10.33), checks for 40 random invariant densities that every one has eight positive and eight negative eigenvalues, sorts the 28 generators into unitary, commuting with B and Krein-unitary (Section 10.34), and follows a column under a rotation and two boosts. It draws five figures and ends with the line ALL 15 CHECKS PASSED (notebook 10e).

10.36 How to run Notebook 10e

Step 1. What this notebook does and what it needs.

Notebook 10e (Invariant forms and Krein-unitary symmetries) is the file `Revision/textbook/notebooks/10e_invariant_forms.ipynb` of the repository Dirac_claude. It finds every bilinear form of the 16 components that is invariant under the 28 generators of Spin(4,4) (a two-dimensional family, spanned by C times the two chiral projectors), shows that every charge density built from such a form and the time direction x4 has as many negative as positive eigenvalues, so that no choice makes the charge positive; it then sorts the 28 generators by whether they keep the canonical anticommutator (Krein-unitary: the 21 that do not involve x4) and whether they are unitary (9 do both), follows finite rotations and boosts, reproduces the recorded checks, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10e_invariant_forms.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10e_invariant_forms.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10e_invariant_forms.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10e.captions.json`
- `Revision/textbook/figures/10e_1_invariant_forms.png`
- `Revision/textbook/figures/10e_2_singular_values.png`
- `Revision/textbook/figures/10e_3_density_eigenvalues.png`
- `Revision/textbook/figures/10e_4_generator_types.png`
- `Revision/textbook/figures/10e_5_finite_transformations.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10e_5_finite_transformations.png exists
ALL 15 CHECKS PASSED (notebook 10e)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10e_invariant_forms.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10e_invariant_forms.ipynb
python -m nbconvert --execute --inplace 10e_invariant_forms.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.37 Notebook 10e: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10e_invariant_forms.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The canonical anticommutator of dirac16complex contains the matrix $B =
-iC\gamma^{(x_4)}$, which has eight positive and eight negative eigenvalues: the
charge $\Psi^\dagger B\Psi$ is indefinite. Could a cleverer choice of the charge
density avoid this? This notebook answers no, and then asks which symmetry
transformations of the spinor keep the canonical anticommutator. It

- finds EVERY matrix $G$ for which the bilinear form $\Psi^TG\Phi$ is unchanged by
  the 28 generators $S^{ab} = \frac14[\gamma^{(x_a)}, \gamma^{(x_b)}]$ of Spin(4,4):
  the solutions form a two-dimensional family, spanned by $CP_-$ and $CP_+$, where
  $P_\mp = \frac12(I \mp \Gamma)$ are the projectors onto the two chiral halves;
- shows that every charge density made from such a form and the time direction,
  the Hermitian part of $cG\gamma^{(x_4)}$, satisfies $\Gamma X\Gamma = -X$ and
  therefore has as many negative as positive eigenvalues (unless it is zero);
- sorts the 28 generators: which are anti-Hermitian (their exponentials are
  unitary), which commute with $B$, and which are *Krein-unitary* (their
  exponentials keep $B$): exactly the 21 generators that do not involve $x_4$, the
  generators of Spin(4,3);
- follows finite rotations and boosts and draws what happens to the ordinary
  squared length and to the Krein norm of a column;
- reproduces the recorded checks and draws five teaching figures.
```

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 10e (Invariant forms and Krein-unitary symmetries) is the file ‘Revision/textbook/notebooks/10e_invariant_forms.ipynb‘ of the repository Dirac_claude. It finds every bilinear form of the 16 components that is invariant under the 28 generators of Spin(4,4) (a two-dimensional family, spanned by C times the two chiral projectors), shows that every charge density built from such a form and the time direction x4 has as many negative as positive eigenvalues, so that no choice makes the charge positive; it then sorts the 28 generators by whether they keep the canonical anticommutator (Krein-unitary: the 21 that do not involve x4) and whether they are unitary (9 do both), follows finite rotations and boosts, reproduces the recorded checks, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 10e_invariant_forms.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 10 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.

**Step 6. Or run the notebook without a browser (headless).**
```

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10e_invariant_forms.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10e_invariant_forms.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10e.captions.json‘
- ‘Revision/textbook/figures/10e_1_invariant_forms.png‘
- ‘Revision/textbook/figures/10e_2_singular_values.png‘
- ‘Revision/textbook/figures/10e_3_density_eigenvalues.png‘
- ‘Revision/textbook/figures/10e_4_generator_types.png‘
- ‘Revision/textbook/figures/10e_5_finite_transformations.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10e_5_finite_transformations.png exists
ALL 15 CHECKS PASSED (notebook 10e)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10e_invariant_forms.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 10e_invariant_forms.ipynb
      python -m nbconvert --execute --inplace 10e_invariant_forms.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 10e (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
```

```
# Notebook 10e (Invariant forms and Krein-unitary symmetries) is the file
# Revision/textbook/notebooks/10e_invariant_forms.ipynb of the repository Dirac_claude.
# It finds every bilinear form of the 16 components that is invariant under the 28
# generators of Spin(4,4) (a two-dimensional family, spanned by C times the two chiral
# projectors), shows that every charge density built from such a form and the time
# direction x4 has as many negative as positive eigenvalues, so that no choice makes the
# charge positive; it then sorts the 28 generators by whether they keep the canonical
# anticommutator (Krein-unitary: the 21 that do not involve x4) and whether they are
# unitary (9 do both), follows finite rotations and boosts, reproduces the recorded
# checks, and draws five teaching figures. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
```

```
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10e_invariant_forms.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10e_invariant_forms.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10e_invariant_forms.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
```

```
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10e.captions.json
# - Revision/textbook/figures/10e_1_invariant_forms.png
# - Revision/textbook/figures/10e_2_singular_values.png
# - Revision/textbook/figures/10e_3_density_eigenvalues.png
# - Revision/textbook/figures/10e_4_generator_types.png
# - Revision/textbook/figures/10e_5_finite_transformations.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10e_5_finite_transformations.png exists
#     ALL 15 CHECKS PASSED (notebook 10e)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10e_invariant_forms.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10e_invariant_forms.ipynb
```

```
#     python -m nbconvert --execute --inplace 10e_invariant_forms.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
#
# ------------------------------------------------------------------------------------

Set-up of notebook 10e complete: repository folder found, helpers defined.
```

Text cell:

```
## 3. The words used in this notebook

- **Generator, Spin(4,4)**: the 28 matrices $S^{ab}$ ($a < b$) generate the spin
  transformations $R = \exp(\theta S^{ab})$, which turn the frame of the eight
  directions; their products form Spin(4,4). Spin(4,3) is the part generated by the
  21 $S^{ab}$ with $a, b \neq x_4$ (the transformations that leave the time $x_4$
  alone).
- **Bilinear form, invariant**: a form $\Psi^TG\Phi$ with a $16 \times 16$ matrix $G$.
  It is *invariant* if it does not change when both columns are transformed by the
  same spin transformation; to first order in $\theta$ this is the condition
  $(S^{ab})^TG + GS^{ab} = 0$ for all 28 generators.
```

- **Hermitian form, charge density**: a form $\Psi^\dagger X\Psi$ with a Hermitian matrix X; it is real for every Ψ. A charge density is the time component of a current.
- **Chiral projectors**: $P_\mp = \frac12(I \mp \Gamma)$ with the chirality $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$; P_- keeps components 1 to 8, P_+ components 9 to 16.
- **Singular values**: for a matrix M the square roots of the eigenvalues of M^TM. The number of zero singular values of M is the number of independent solutions of $Mx = 0$.
- **Unitary, Krein-unitary**: R is unitary if $R^\dagger R = I$ (it keeps the ordinary length), Krein-unitary if $R^\dagger BR = B$ (it keeps the Krein form and the canonical anticommutator). For $R = \exp(\theta S)$ the first-order conditions are $S^\dagger = -S$ and $S^\dagger B + BS = 0$.
- **Rotation, boost**: $R = \exp(\theta S^{ab})$ is a rotation when a and b are both space-like or both time-like ($S^2 = -\frac14 I$, cosines and sines), and a boost when one is space-like and one time-like ($S^2 = +\frac14 I$, hyperbolic cosines and sines).

Text cell:

```
## 4. The physical and mathematical situation
```

Why invariant forms are the right candidates. Under a spin transformation $\Psi \to R\Psi$ the form $\Psi^TG\Psi$ becomes $\Psi^TR^TGR\Psi$. For $R = I + \theta S$ with small θ, $R^TGR = G + \theta(S^TG + GS) + \theta^2S^TGS$; the form is unchanged to first order exactly when $S^TG + GS = 0$. The gammas, and hence the S^{ab}, are real, so $S^\dagger = S^T$, and the same condition makes the Hermitian form $\Psi^\dagger G\Psi$ invariant. The notebook solves these 28×256 linear equations for the 256 entries of G.

Why every such density is indefinite. The solutions will be $G = r_-CP_- + r_+CP_+$. Both C and $P_\mp$ commute with Γ (C is a product of four gammas, an even number), so G commutes with Γ; $\gamma^{(x_4)}$ anticommutes with Γ. Hence $\Gamma(cG\gamma^{(x_4)})\Gamma = cG\Gamma\gamma^{(x_4)}\Gamma = -cG\gamma^{(x_4)}$, and the same for its Hermitian part X: $\Gamma X\Gamma = -X$. If $Xv = \lambda v$, then $X(\Gamma v) = -\Gamma Xv = -\lambda\,\Gamma v$: every eigenvalue λ comes with $-\lambda$, with the same multiplicity. So the density $\Psi^\dagger X\Psi$ is indefinite unless $X = 0$. The canonical choice is $B = -iC\gamma^{(x_4)}$ ($r_- = r_+ = 1$, $c = -i$).

Which transformations keep B. B is $-i$ times the product of the five gammas $\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}\gamma^{(x_4)}$. A gamma of x_1, x_2, x_3, x_4, x_0 anticommutes with four of the five factors and commutes with itself, so it commutes with B; a gamma of x_5, x_6, x_7 anticommutes with all five and so anticommutes with B. For an anti-Hermitian generator the Krein condition $S^\dagger B + BS = 0$ means $[B, S] = 0$; for a Hermitian one it means $\{B, S\} = 0$. The notebook counts the generators of each kind.

Text cell:

```
## 5. The gammas, the generators and the chiral projectors
```

The next cell reads the gammas, builds C, Γ, B, the projectors $P_\mp$,
the 28 generators S^{ab} ($a < b$) and the helper ‘check_record‘ (the PASS line
and the line of the reproduced Revision record are printed in one piece, so that
the stored output is the same in every run). It checks the recorded relations of
B with the gammas.
Before it checks anything, ‘check_record‘ asks the helper ‘record_says_pass‘ whether
the cited record still says PASS: for a record name of the form
‘<report file>, check <check name>‘ it opens that report (each file once, kept in
the dictionary ‘REPORT_CHECKS‘) and stops the notebook with an error unless a check
of that name exists there with the verdict PASS; a record name without ‘, check ‘
names a data entry that the notebook reads and compares itself.

In [2]:

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import itertools  # all pairs (a, b) with a < b
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices

## 6. Every invariant bilinear form

The unknown $G$ has 256 entries; write them as one long column $\vec G$ (row after
row). The matrix equation $S^TG + GS = 0$ is linear in $\vec G$: with the rule
"the row-by-row column of $AXD$ is $(A \otimes D^T)\vec X$" ($\otimes$ is the
Kronecker product, `np.kron`), it reads $(S^T \otimes I + I \otimes S^T)\vec G = 0$.
Stacking the 28 generators gives a matrix $M$ with $28 \cdot 256 = 7168$ rows and
256 columns, and the invariant forms are the solutions of $M\vec G = 0$.

The number of independent solutions is the number of zero singular values of $M$,
that is the number of zero eigenvalues of the $256 \times 256$ matrix $M^TM$. The
next cell computes them. Because $M$ is made of the numbers $0, \pm\frac14,
\pm\frac12$, a nonzero eigenvalue of $M^TM$ cannot be tiny; the cell prints the
smallest nonzero one and the largest "zero" one, to show that the separation is
enormous, so rounding cannot change the count. Then it checks EXACTLY (the entries
of $C$, $P_\mp$ and $S^{ab}$ are multiples of $\frac12$ and $\frac14$, which the
computer stores without rounding) that $CP_-$ and $CP_+$ solve every equation and
are independent, so they span the whole solution space.
```

## 8. Which generators keep the canonical anticommutator?

The next cell sorts the 28 generators. For each it records whether it is
anti-Hermitian ($S^\dagger = -S$; its exponential is then unitary), whether it
commutes with $B$, and whether it satisfies the Krein condition $S^\dagger B + BS
= 0$ (its exponential then keeps $B$ and the canonical anticommutator). The Revision
record states that the Krein condition holds exactly for the 21 generators with
$a, b \neq x_4$ and that for the 7 generators $S^{(x_4b)}$ (with $x_4$ written first)
the left-hand side equals $iC\gamma^{(x_b)}$.
```

## 9. Finite rotations and boosts

Since $(\gamma^{(x_a)}\gamma^{(x_b)})^2 = -\eta_{aa}\eta_{bb}I$ for $a \neq b$, the
generator obeys $(S^{ab})^2 = -\frac14\eta_{aa}\eta_{bb}I$, and the exponential series
collapses: for $\eta_{aa}\eta_{bb} = +1$ (a rotation) $\exp(\theta S) =
\cos\frac\theta2\,I + 2\sin\frac\theta2\,S$, and for $\eta_{aa}\eta_{bb} = -1$ (a
boost) $\exp(\theta S) = \cosh\frac\theta2\,I + 2\sinh\frac\theta2\,S$. The next
cell checks the formula against a numerical matrix exponential (the sum of the
series up to the 30th power) and then follows a column $u$ with $u^\dagger u = 1$ and
$u^\dagger Bu = 1$ under three transformations: the rotation $S^{(x_1x_2)}$, the
boost $S^{(x_1x_5)}$ (Krein-unitary) and the boost $S^{(x_1x_4)}$ (not
Krein-unitary). It plots the squared length $(Ru)^\dagger(Ru)$ and the Krein norm
$(Ru)^\dagger B(Ru)$ against $\theta$.

PASS the figure file 10e_2_singular_values.png exists
PASS the figure file 10e_3_density_eigenvalues.png exists
PASS the figure file 10e_4_generator_types.png exists
PASS the figure file 10e_5_finite_transformations.png exists
ALL 15 CHECKS PASSED (notebook 10e)
```

Text cell:

```
## 11. What this notebook showed

- COMPUTED (with a separation of many orders of magnitude between zero and nonzero
  eigenvalues) and CHECKED EXACTLY: the bilinear forms invariant under all 28
  generators of Spin(4,4) form a two-dimensional family, spanned by $CP_-$ and
  $CP_+$; $C$ itself gives the scalar $\bar\Psi\Psi$.
- PROVED (Section 4) and CHECKED for 40 random choices: every charge density built
  from an invariant form and the time gamma, the Hermitian part of
  $cG\gamma^{(x_4)}$, satisfies $\Gamma X\Gamma = -X$ and has eight positive and
  eight negative eigenvalues. The indefinite (Krein) charge of dirac16complex is not
  an accident of the choice $B$: in signature (4,4) no invariant density is
  positive.
- REPRODUCED: exactly the 21 generators that do not involve $x_4$ are
  Krein-unitary (they generate Spin(4,3), the transformations that keep the
  canonical anticommutator), and for the 7 generators $S^{(x_4b)}$ the defect is
  $iC\gamma^{(x_b)}$; of the 21, the 9 rotations among $x_0, x_1, x_2, x_3$ and among
  $x_5, x_6, x_7$ are also unitary. COMPUTED: the counts 12 (anti-Hermitian) and 13
  (commuting with $B$).
- The canonical structure singles out the time $x_4$, as $\Psi^\dagger\Psi$ does in
  ordinary Dirac theory; transformations that turn $x_4$ into another direction
  (here the 7 generators with $x_4$) do not keep $B$, and the slices $x_4 = $ const
  on which the theory is quantised are then changed as well.
```

10.38 Line-by-line walk-through of Notebook 10e

The notebook has 10 code cells, In [1] to In [10]; docstrings are left out of the quotations (they are printed in Section 10.37).

In [1], the set-up cell. Its first 246 lines are comments that repeat the run instructions of Section 10.36. The code is that of In [1] of Notebook 10a (Section 10.10), with the line `NOTEBOOK_ID = "10e" # this notebook: chapter 10, example e`. It prints `Set-up of notebook 10e complete: repository folder found, helpers defined.`

In [2], the gammas, the generators and the chiral projectors.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import itertools  # all pairs (a, b) with a < b
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices
from matplotlib.colors import LinearSegmentedColormap, ListedColormap  # colours

REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
```

```
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"

def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

The imports of In [2] of Notebook 10a, and in addition `itertools`, a module of Python that lists combinations, and two kinds of colour scales of matplotlib. `REPORT_CHECKS`, `record_says_pass` and `check_record` are the helpers of Section 10.10 (a cited report check must still exist with the verdict PASS; the two printed lines come in one piece).

```
BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
DIVERGING = LinearSegmentedColormap.from_list(
    "blue_grey_red", ["#184f95", "#f0efec", "#e34948"])
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
gamma = {a: np.array(fixture["gamma"][a], dtype=float) for a in range(8)}
eta = {a: fixture["eta"][a] for a in range(8)}
I16 = np.eye(16)
```

The colours and the blue-grey-red colour scale of Notebook 10a; the gammas of the record as decimal numbers, the signs η_{aa} of the frame metric, and the identity I_{16}.

```
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]
Gamma = (gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5]
         @ gamma[6] @ gamma[7])
B = -1j * (C @ gamma[4])
P_minus, P_plus = (I16 - Gamma) / 2, (I16 + Gamma) / 2  # the chiral projectors
```

C, the chirality Γ, B, and the projectors $P_{\mp} = \frac{1}{2}(I_{16} \mp \Gamma)$; since $\Gamma = \mathrm{diag}(-I_8, I_8)$, P_- keeps the components 1 to 8 and P_+ the components 9 to 16.

```
pairs = list(itertools.combinations(range(8), 2))  # (0, 1), (0, 2), ..., (6, 7)
S = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4 for a, b in pairs}
report("number of generators S^ab", len(S))
```

`itertools.combinations(range(8), 2)` lists every pair (a, b) with $a < b$ from 0 to 7, $\binom{8}{2} = 28$ pairs. The dictionary `S` stores $S^{ab} = \frac{1}{4}(\gamma^{(x_a)}\gamma^{(x_b)} - \gamma^{(x_b)}\gamma^{(x_a)})$ for each pair; the RESULT line prints 28.

```
commuting = [a for a in range(8) if np.array_equal(B @ gamma[a], gamma[a] @ B)]
anticommuting = [a for a in range(8) if np.array_equal(B @ gamma[a], -gamma[a] @ B)]
```

```
say(f"B commutes with gamma^(x_a) for a = {commuting}, anticommutes for a = "
    f"{anticommuting}")
check_record(commuting == [0, 1, 2, 3, 4] and anticommuting == [5, 6, 7],
             "B commutes with the gammas of x0, x1, x2, x3, x4, anticommutes with x5-x7",
             record="Revision/algebra/reports/python-algebra.json, check "
                    "B_gamma_relations")
```

The lists of the directions whose gamma commutes or anticommutes with B. The printed line shows `[0, 1, 2, 3, 4]` and `[5, 6, 7]`, as Section 10.2 derived, and the check reproduces the record check `B_gamma_relations`.

In [3], every invariant bilinear form.

```
rows = [np.kron(s.T, I16) + np.kron(I16, s.T) for s in S.values()]
M = np.vstack(rows)  # 7168 rows, 256 columns
values = np.linalg.eigvalsh(M.T @ M)  # 256 eigenvalues, sorted, all >= 0
zero_count = int(np.sum(values < 1e-9))
```

The unknown G has 256 entries; write them, row after row, as one long column $\vec{G}$. The rule "the row-by-row column of XGY is $(X \otimes Y^T)\vec{G}$", where $\otimes$ is the **Kronecker product** (`np.kron`: the matrix made of the blocks $X_{ij}Y^T$), turns $S^TG = S^TGI_{16}$ into $(S^T \otimes I_{16})\vec{G}$ and $GS = I_{16}GS$ into $(I_{16} \otimes S^T)\vec{G}$. So each generator gives a 256×256 block of equations, and `np.vstack` stacks the 28 blocks into the matrix M with $28 \times 256 = 7168$ rows. The invariant forms are the solutions of $M\vec{G} = 0$. Their number equals the number of zero eigenvalues of the 256×256 matrix M^TM (if $M^TM\vec{G} = 0$ then $\vec{G}^TM^TM\vec{G} = \|M\vec{G}\|^2 = 0$, so $M\vec{G} = 0$). `np.linalg.eigvalsh` computes its 256 eigenvalues, sorted, and `zero_count` counts those below 10^{-9}.

```
report("shape of M", M.shape)
report("eigenvalues of M^T M below 1e-9 (independent invariant forms)", zero_count)
report("largest of them and smallest nonzero eigenvalue",
       f"{values[zero_count - 1]:.1e} and {values[zero_count]:.4f}")
```

The printed lines show the shape `(7168, 256)`, two zero eigenvalues, the larger of them 1.3×10^{-15} (rounding) and the smallest nonzero eigenvalue 7.0000: a separation of about fifteen orders of magnitude, so rounding cannot change the count.

```
forms = {"C P_minus": C @ P_minus, "C P_plus": C @ P_plus}
exact_ok = all(np.array_equal(s.T @ G + G @ s, np.zeros((16, 16)))
               for G in forms.values() for s in S.values())
independent = np.linalg.matrix_rank(np.vstack([G.reshape(1, -1)
                                               for G in forms.values()])) == 2
check(zero_count == 2 and exact_ok and independent,
      "the invariant bilinear forms are exactly the combinations of C P- and C P+")
```

The two candidates CP_- and CP_+ of Section 10.33. Their entries, and those of the S^{ab}, are multiples of $\frac{1}{2}$ and $\frac{1}{4}$, which the computer stores without rounding, so `np.array_equal` checks $S^TG + GS = 0$ exactly for both forms and all 28 generators. `G.reshape(1, -1)` writes a matrix as one row of 256 numbers; the two rows stacked have rank 2, so the two forms are independent. With exactly two zero eigenvalues they span all solutions.

```
check_record(all(np.array_equal(s.T @ C + C @ s, np.zeros((16, 16)))
                 for s in S.values()),
             "C itself (= C P- + C P+) is invariant: Psibar Psi is a Spin(4,4) scalar",
             record="Revision/algebra/reports/wolfram-algebra.json, check "
                    "S_preserves_C")
check_record(all(np.array_equal(Gamma @ s, s @ Gamma) for s in S.values()),
             "every generator commutes with Gamma: the chiral halves are invariant",
             record="Revision/algebra/reports/python-algebra.json, check "
                    "S_preserves_C_and_commutes_with_Gamma")
```

Two facts of the Revision algebra record: C itself is invariant, and every generator commutes with Γ (a product of two gammas passes Γ with the sign $(-1)^2 = +1$). The cell prints three PASS lines.

In [4], pictures of the invariant forms and of the eigenvalues.

```
titles = {"C P_minus": "$CP_-$ (components 1 to 8)",
          "C P_plus": "$CP_+$ (components 9 to 16)"}
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.0))
for ax, (label, G) in zip(axes, forms.items()):
    image = ax.imshow(G, cmap=DIVERGING, vmin=-1, vmax=1)
    ticks = list(range(0, 16, 3))
    ax.set_xticks(ticks, [str(t + 1) for t in ticks])
    ax.set_yticks(ticks, [str(t + 1) for t in ticks])
    ax.grid(False)
    ax.set_title(titles[label])
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry")
save_figure(fig, "invariant_forms",
...)
```

The two forms as heat maps, with the steps of the function `draw_matrix` of Notebook 10a written out (rows and columns labelled from 1 at every third one, no grid). Figure 1 of Notebook 10e shows CP_- filled only in the upper left 8×8 block and CP_+ only in the lower right one, each block with one red or blue square per row and column; together they make C.

```
fig, ax = plt.subplots()
ax.semilogy(range(1, 257), np.maximum(values, 1e-18), "o", color=BLUE, markersize=3)
ax.axhline(1e-9, color=GREY, linestyle=":", linewidth=1)
ax.set_xlabel("number of the eigenvalue (sorted)")
ax.set_ylabel("eigenvalue of $M^TM$ (log scale)")
ax.set_title("Two zero eigenvalues: two invariant forms")
save_figure(fig, "singular_values",
...)
```

`ax.semilogy` draws with a logarithmic vertical axis; values below 10^{-18} (the zeros, which rounding may even make slightly negative) are drawn at 10^{-18}. The dotted line marks the threshold 10^{-9}. Figure 2 of Notebook 10e shows two points far down at the rounding level and all 254 others at about 7 or higher: two invariant forms.

In [5], every invariant charge density is indefinite.

```
rng = np.random.default_rng(12345)
spectra, all_ok = [], True
for _ in range(40):
    r_minus, r_plus = rng.normal(size=2)
    c = complex(rng.normal(), rng.normal())
    G = r_minus * C @ P_minus + r_plus * C @ P_plus
    Y = c * G @ gamma[4]
    X = (Y + Y.conj().T) / 2  # the Hermitian part
```

For 40 random choices: two real coefficients $r_{\mp}$ (the two values returned by `rng.normal(size=2)` are given two names at once), a random complex number c, the invariant form $G = r_{-}CP_{-} + r_{+}CP_{+}$ (real coefficients, so that G is Hermitian), $Y = cG\gamma^{(x_4)}$ and its Hermitian part X (Section 10.33).

```
    eigenvalues = np.linalg.eigvalsh(X)
    spectra.append(eigenvalues)
    positive = int(np.sum(eigenvalues > 1e-12))  # how many eigenvalues are > 0
    negative = int(np.sum(eigenvalues < -1e-12))  # how many are < 0
    all_ok = (all_ok and np.allclose(Gamma @ X @ Gamma, -X)
              and positive == 8 and negative == 8)
```

The 16 eigenvalues of X are stored for the figure and counted by sign; `all_ok` stays true while every sample has $\Gamma X \Gamma = -X$ (`np.allclose` allows rounding) and eight eigenvalues of each sign.

```
G_canonical = C @ P_minus + C @ P_plus  # = C
Y = -1j * G_canonical @ gamma[4]
X_canonical = (Y + Y.conj().T) / 2
canonical_ok = np.allclose(X_canonical, B)
canonical_values = np.linalg.eigvalsh(X_canonical)
check(all_ok,
      "40 random invariant densities: Gamma X Gamma = -X, 8 positive, 8 negative")
check_record(canonical_ok and np.allclose(canonical_values, [-1] * 8 + [1] * 8),
             "the canonical density is B, with eigenvalues -1 and +1, eight each",
             record="Revision/algebra/reports/wolfram-algebra.json, check "
                    "B_signature_8_8")
```

The canonical choice $r_{\mp} = 1$, $c = -i$ gives $X = B$ with the sorted eigenvalues eight times -1 and eight times $+1$. Two PASS lines; the second reproduces the record check `B_signature_8_8`.

```
fig, ax = plt.subplots()
for index, eigenvalues in enumerate(spectra, 1):
    ax.plot([index] * 16, eigenvalues, "_", color=BLUE if index % 2 else GREEN,
            markersize=10, markeredgewidth=2)
ax.plot([42] * 16, canonical_values, "_", color=ORANGE, markersize=12,
        markeredgewidth=3)
ax.annotate("$B$", (42, 1.0), xytext=(40.5, 1.6), color=ORANGE)
ax.axhline(0.0, color=GREY, linewidth=1)
ax.set_xlabel("random invariant density (1 to 40), and the canonical $B$ (42)")
ax.set_ylabel("eigenvalues of the density matrix $X$")
ax.set_title("Every invariant charge density is indefinite")
save_figure(fig, "density_eigenvalues",
...)
```

`enumerate(spectra, 1)` numbers the samples from 1. Each sample is drawn as 16 short horizontal marks (the marker `"_"`) at its eigenvalues, above its number; the colours alternate between blue and green, and B is drawn in orange at position 42. Figure 3 of Notebook 10e shows for every sample marks above and below the grey zero line in mirror-image positions: eigenvalues in pairs $\pm\lambda$, eight of each sign, as Section 10.33 proved.

In [6], which generators keep the canonical rule.

```
kinds = {}
for (a, b), s in S.items():
    anti_hermitian = np.array_equal(s.conj().T, -s)
    commutes = np.allclose(B @ s, s @ B)
    krein = np.allclose(s.conj().T @ B + B @ s, 0)
    kinds[(a, b)] = (anti_hermitian, commutes, krein)
```

For each generator three truth values are stored: anti-Hermitian ($S^\dagger = -S$), commuting with B, and the Krein condition $S^\dagger B + BS = 0$ (Section 10.34).

```
counts = {"anti-Hermitian (unitary)": sum(k[0] for k in kinds.values()),
          "commute with B": sum(k[1] for k in kinds.values()),
          "Krein-unitary": sum(k[2] for k in kinds.values()),
          "both unitary and Krein-unitary": sum(k[0] and k[2] for k in kinds.values())}
for label, number in counts.items():
    report(label, number)
```

Summing truth values counts the true ones (`True` counts as 1). The RESULT lines print 12 anti-Hermitian generators, 13 that commute with B, 21 Krein-unitary ones and 9 that are both: the counts derived in Section 10.34.

```
krein_pairs = sorted(pair for pair, k in kinds.items() if k[2])
off_x4 = sorted(pair for pair in pairs if 4 not in pair)
x4_ok = True
for (a, b), s in S.items():
    if 4 in (a, b):
        other = b if a == 4 else a
        s_x4_first = s if a == 4 else -s  # S^(x4 b) = -S^(b x4)
        left = s_x4_first.conj().T @ B + B @ s_x4_first
        x4_ok = x4_ok and np.allclose(left, 1j * C @ gamma[other])
```

`krein_pairs` is the sorted list of the Krein-unitary pairs, `off_x4` the sorted list of the pairs without the direction 4. For each of the 7 pairs that contain 4, the generator is written with x_4 first ($S^{ab} = -S^{ba}$, so for the pairs $(1,4)$, $(2,4)$, $(3,4)$ the sign is reversed), and the defect $S^\dagger B + BS$ is compared with $iC\gamma^{(x_b)}$, b being the other direction.

```
check_record(krein_pairs == off_x4 and len(krein_pairs) == 21 and x4_ok,
             "Krein-unitary: exactly the 21 generators without x4 (Spin(4,3))",
             record="Revision/algebra/reports/wolfram-algebra.json, check "
                    "S_preserves_B_only_off_x4")
check(counts["anti-Hermitian (unitary)"] == 12 and counts["commute with B"] == 13
      and counts["both unitary and Krein-unitary"] == 9,
      "counts: 12 anti-Hermitian, 13 commute with B, 9 both unitary and Krein")
```

The first check reproduces the record check `S_preserves_B_only_off_x4`: the Krein-unitary generators are exactly the 21 without x_4, and the 7 with x_4 have the defect $iC\gamma^{(x_b)}$. The second confirms the counts. Two PASS lines.

In [7], the 28 generators as a picture.

```
grid = np.full((8, 8), np.nan)  # NaN: no generator (diagonal and below)
for (a, b), (anti_hermitian, _, krein) in kinds.items():
    grid[a - 1, b - 1] = 0 if (anti_hermitian and krein) else (1 if krein else 2)
colours = ListedColormap([BLUE, GREEN, ORANGE])
fig, ax = plt.subplots(figsize=(6.0, 5.4))
ax.imshow(grid, cmap=colours, vmin=-0.5, vmax=2.5)
```

An 8×8 table, empty (NaN, drawn white) on and below the diagonal; above it, the square of row a and column b gets 0 for a generator that is unitary and Krein-unitary, 1 for Krein-unitary only, 2 otherwise. `ListedColormap` is a colour scale of three fixed colours; with the range from -0.5 to 2.5 the values 0, 1 and 2 fall into its three thirds: blue, green and orange.

```
names = [f"$x_{a}$" for a in range(8)]
ax.set_xticks(range(8), names)
ax.set_yticks(range(8), names)
ax.grid(False)
for (a, b), (anti_hermitian, _, krein) in kinds.items():
    mark = "rot" if anti_hermitian else "boost"  # a rotation or a boost
    ax.text(b - 1, a - 1, mark, ha="center", va="center", color="white", fontsize=7)
```

The rows and columns are labelled x_0 to x_7, and each square gets the word `rot` (an anti-Hermitian generator, a rotation) or `boost` (a Hermitian one), written in white at its centre.

```
ax.plot([], [], "s", color=BLUE, label="unitary and Krein-unitary (9)")
ax.plot([], [], "s", color=GREEN, label="Krein-unitary only (12)")
ax.plot([], [], "s", color=ORANGE, label="breaks the anticommutator (7)")
ax.legend(loc="lower left", fontsize=8)
ax.set_xlabel("second direction $b$")
ax.set_ylabel("first direction $a$")
ax.set_title("The 28 generators $S^{ab}$ and the canonical anticommutator")
save_figure(fig, "generator_types",
...)
```

Empty plots with square markers create the three legend entries, placed in the empty lower left corner. Figure 4 of Notebook 10e shows the column and the row of x_4 orange (the 7 generators that break the canonical rule), blue rotations among x_1, x_2, x_3 and x_0 and among x_5, x_6, x_7, and green boosts between those two groups.

In [8], finite rotations and boosts.

```
def spin_transformation(a, b, theta):
    s = S[(a, b)]
    if eta[a] * eta[b] == 1:  # a rotation
```

```
        return np.cos(theta / 2) * I16 + 2 * np.sin(theta / 2) * s
    return np.cosh(theta / 2) * I16 + 2 * np.sinh(theta / 2) * s  # a boost

def series_exponential(matrix, terms=30):
    result, power = np.eye(16), np.eye(16)
    for n in range(1, terms + 1):
        power = power @ matrix / n
        result = result + power
    return result
```

`spin_transformation` is the closed formula of Section 10.34; `series_exponential` sums the power series $\sum_{n=0}^{30} X^n/n!$ directly (each pass multiplies the previous term by X/n, so `power` is $X^n/n!$).

```
worst = max(np.max(np.abs(spin_transformation(a, b, 0.7)
                          - series_exponential(0.7 * S[(a, b)]))) for a, b in pairs)
report("largest difference between the formula and the series", f"{worst:.1e}")
check(worst < 1e-12, "the closed formula for exp(theta S^ab) is right for all 28")
```

For $\theta = 0.7$ and all 28 generators the two agree to 6.7×10^{-16}, printed as `6.7e-16`.

```
u = ((I16 + B) / 2)[:, 0]  # a column with B u = u
u = u / np.linalg.norm(u)
thetas = np.linspace(-3.0, 3.0, 241)
curves = {}
for pair in ((1, 2), (1, 5), (1, 4)):
    lengths, kreins = [], []
    for theta in thetas:
        v = spin_transformation(*pair, theta) @ u
        lengths.append((v.conj() @ v).real)
        kreins.append((v.conj() @ B @ v).real)
    curves[pair] = (np.array(lengths), np.array(kreins))
```

A column u with $Bu = u$ and length 1 (so its Krein norm is 1) is transformed by the rotation $S^{(x_1x_2)}$, the boost $S^{(x_1x_5)}$ and the boost $S^{(x_1x_4)}$ for 241 values of θ from -3 to 3, and its ordinary squared length and its Krein norm are stored. `spin_transformation(*pair, theta)` passes the two numbers of the pair as the first two arguments.

```
kept = {pair: np.max(np.abs(curves[pair][1] - 1)) < 1e-12 for pair in curves}
say(f"Krein norm kept: rotation x1x2 {kept[(1, 2)]}, boost x1x5 {kept[(1, 5)]}, "
    f"boost x1x4 {kept[(1, 4)]}")
check(kept[(1, 2)] and kept[(1, 5)] and not kept[(1, 4)]
      and np.max(np.abs(curves[(1, 2)][0] - 1)) < 1e-12,
      "finite: the rotation keeps both norms, the x1x5 boost only the Krein norm")
```

The printed line shows that the Krein norm is kept by the rotation and the x_1x_5 boost (`True`) but not by the x_1x_4 boost (`False`); the check also requires the rotation to keep the ordinary length. Two PASS lines in the cell.

In [9], the two norms in a picture.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharex=True)
styles = {(1, 2): (BLUE, "-", "rotation $S^{(x_1x_2)}$"),
          (1, 5): (GREEN, "--", "boost $S^{(x_1x_5)}$"),
          (1, 4): (ORANGE, ":", "boost $S^{(x_1x_4)}$")}
for pair, (colour, style, label) in styles.items():
    axes[0].plot(thetas, curves[pair][0], style, color=colour, linewidth=2,
                 label=label)
    axes[1].plot(thetas, curves[pair][1], style, color=colour, linewidth=2,
                 label=label)
```

Each transformation gets a colour, a line style (solid, dashed, dotted) and a label; the left panel draws the ordinary squared lengths $(Ru)^\dagger(Ru)$, the right panel the Krein norms.

```
axes[0].set_ylabel("squared length $(Ru)^\\dagger(Ru)$")
axes[1].set_ylabel("Krein norm $(Ru)^\\dagger B (Ru)$")
for ax in axes:
    ax.set_xlabel("angle or rapidity $\\theta$")
    ax.legend(fontsize=8)
axes[0].set_title("unitary: only the rotation keeps the length")
axes[1].set_title("Krein-unitary: the rotation and the $x_1x_5$ boost")
save_figure(fig, "finite_transformations",
...)
```

Figure 5 of Notebook 10e shows on the left the rotation flat at 1 while both boosts rise ($\cosh\theta$ for the x_1x_5 boost, Section 10.34), and on the right the rotation and the x_1x_5 boost flat at 1 while the x_1x_4 boost moves away: a boost between a space direction and an extra time keeps the canonical rule, a boost that involves the time x_4 does not.

In [10], the last check.

```
for name in ("10e_1_invariant_forms.png", "10e_2_singular_values.png",
             "10e_3_density_eigenvalues.png", "10e_4_generator_types.png",
             "10e_5_finite_transformations.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The five figure files exist, and the last line prints ALL 15 CHECKS PASSED (notebook 10e): the five figure checks and the 10 checks of the cells before (1 in In [2], 3 in In [3], 2 each in In [5], In [6] and In [8]).

10.39 The Krein structure along the deflating history

Sections 10.3 to 10.6 studied waves with momenta that do not change. In the author's metric they DO change: the three extra times x_5, x_6, x_7 deflate exponentially (scale factor $e^{-a_4}\sin^{1/6} z$, with a_4 increasing), and 3-space inflates (scale factor $e^{a_4}\sin^{1/6} z$). This section follows the one-particle structure of the chapter along the deflating history that the Kohn-Sham record uses.

The history and its status. The Kohn-Sham record takes the linear history

$$a_4 = AHx_4, \qquad A = H = m = 1$$

(record `Revision/kohn_sham/results/parameters.json`, entries `physics.historyA`, `physics.H`, `physics.m`; its slices are $a_{4,0} = 0, 0.5, 1, 1.5, 2$). This history is a PRESCRIBED BACKGROUND: it is not solved from the field equations for a_4 with this field as the source, and the Kohn-Sham states violate the source conditions that the linear member requires (`Revision/field_equations_a4/reports/ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`; Chapter 17). Every statement of this section is made under this ASSUMPTION.

The local-frame model. At each instant x_4 and at one hidden position, the coefficients of the wave equation are evaluated there and the two hidden-direction terms of Section 10.27 are left out; this is the *local-frame* (WKB-type) statement of the Revision record that "every extra-time mode eventually enters the growing regime" (`python-field-theory.json`, check `extra_time_modes_grow`). The model is an ASSUMPTION; the extra times are never treated as static: their scale factor changes at every instant. The Kohn-Sham record measures the hidden direction by $y = \ln(\sin z)/(6H)$, so that

$$\sin^{1/6} z = e^{\ln(\sin z)/6} = e^{Hy},$$

the patch end $z = \pi/2$ is $y = 0$, and $y < 0$ lies towards the tip.

The wave equation of one instant, line by line. Take a wave $\Psi = u(x_4)\, e^{i(q_1 x_1 + q_5 x_5)}$ with the **coordinate momenta** q_1 (along 3-space) and q_5 (along an extra time). In the field equation of Section 10.27 the derivative ∂_1 becomes iq_1 and ∂_5 becomes iq_5, each divided by its scale factor:

$$ik_1\gamma^{(x_1)}u + \gamma^{(x_4)}\frac{du}{dx_4} + ik_5\gamma^{(x_5)}u = mu,$$

with the frame momenta

$$k_1 = \frac{q_1}{e^{a_4}\sin^{1/6} z} = q_1 e^{-AHx_4 - Hy}, \qquad k_5 = \frac{q_5}{e^{-a_4}\sin^{1/6} z} = q_5 e^{AHx_4 - Hy}.$$

The **frame momentum** k_1 SHRINKS as 3-space inflates; k_5 GROWS as the extra times deflate. The steps of Section 10.3 (multiply by $\gamma^{(x_4)}$, solve for du/dx_4, multiply by i) give

$$i\frac{du}{dx_4} = h(x_4)\, u, \qquad h(x_4) = -im\gamma^{(x_4)} - k_1(x_4)\,\gamma^{(x_4)}\gamma^{(x_1)} - k_5(x_4)\,\gamma^{(x_4)}\gamma^{(x_5)}.$$

At every instant this is a mode Hamiltonian of Section 10.3 with real frame momenta, so by Section 10.4

$$h(x_4)^2 = w(x_4)^2 I_{16}, \qquad w(x_4)^2 = m^2 + k_1^2 - k_5^2 = m^2 + q_1^2 e^{-2AHx_4 - 2Hy} - q_5^2 e^{2AHx_4 - 2Hy}.$$

For $A > 0$ the second term falls and the third grows, so w^2 falls all the time, and if $q_5 \neq 0$ it becomes negative after a finite time: every wave with an extra-time momentum eventually grows.

The onset time, line by line. Write $X = e^{2AHx_4} > 0$ and $c = e^{-2Hy} > 0$. Then $e^{-2AHx_4 - 2Hy} = c/X$ and $e^{2AHx_4 - 2Hy} = cX$, and the condition $w^2 = 0$ reads

$$m^2 + q_1^2\,\frac{c}{X} - q_5^2\,cX = 0.$$

Multiply by $-X$ (which is not 0):

$$q_5^2 c\,X^2 - m^2 X - q_1^2 c = 0.$$

This is a quadratic equation $aX^2 + bX + d = 0$ with $a = q_5^2 c$, $b = -m^2$, $d = -q_1^2 c$; its roots are $X = (-b \pm \sqrt{b^2 - 4ad})/(2a)$, here $(m^2 \pm \sqrt{m^4 + 4q_1^2 q_5^2 c^2})/(2q_5^2 c)$. The square root is at least m^2, so the root with the minus sign is negative (or 0 when $q_1 = 0$), while $X = e^{2AHx_4}$ is positive. The only possible root is

$$X^* = \frac{m^2 + \sqrt{m^4 + 4q_1^2 q_5^2 c^2}}{2q_5^2 c}, \qquad x_4^* = \frac{\ln X^*}{2AH},$$

the **onset time**, by taking the logarithm of $X^* = e^{2AHx_4^*}$. Before x_4^* the frequency is real (the wave oscillates); after it, it is imaginary (the wave grows). For $q_1 = 0$ and $y = 0$ ($c = 1$): $X^* = 2m^2/(2q_5^2) = m^2/q_5^2$ and $x_4^* = \ln(m/q_5)/(AH)$: the onset comes when the growing frame momentum $k_5 = q_5 e^{AHx_4}$ reaches the mass. With $A = H = m = 1$ and $q_5 = 0.05$ this is $\ln 20 \approx 2.996$; Notebook 10f computes the onset of the wave $q_1 = 0.5$, $q_5 = 0.05$, $y = 0$ as 2.996044. The record's exact sample "$m = 1$, $k_5 = 2$: eigenvalues $\pm i\sqrt{3}$" is an instant of this history: the wave $q_1 = 0$, $q_5 = 0.05$ has $k_5 = 0.05\,e^{x_4} = 2$ at $x_4 = \ln 40$.

How far from Hermitian, line by line. By Section 10.4, $-i\gamma^{(x_4)}$ and $\gamma^{(x_4)}\gamma^{(x_1)}$ are Hermitian and commute with B, while $\gamma^{(x_4)}\gamma^{(x_5)}$ is anti-Hermitian and anticommutes with B. So $h = h_H + h_A$ with the anti-Hermitian part

$$h_A = -k_5\,\gamma^{(x_4)}\gamma^{(x_5)},$$

$$h_A^\dagger h_A = -h_A h_A = -k_5^2(\gamma^{(x_4)}\gamma^{(x_5)})^2 = -k_5^2\big(-\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_5)}\gamma^{(x_5)}\big) = k_5^2 I_{16}.$$

The steps: $h_A^\dagger = -h_A$; the square of the product; exchanging the middle factors costs a sign; $\gamma^{(x_4)}\gamma^{(x_4)} = \gamma^{(x_5)}\gamma^{(x_5)} = -I_{16}$. The **size** of a matrix (the largest factor by which it stretches the length of a column) is therefore exactly k_5 for h_A: $\|h_A u\|^2 = u^\dagger h_A^\dagger h_A u = k_5^2\,u^\dagger u$. In the same way $Bh - hB = Bh_A - h_A B = 2Bh_A$ (h_H commutes with B, h_A anticommutes) has the size $2k_5$, because B keeps lengths ($B^\dagger B = BB = I_{16}$). Both sizes grow like e^{a_4}: the deflation drives every wave with extra-time momentum ever further from a Hermitian evolution that keeps the two eigenspaces of B apart. Both vanish at every time in the good sector, $q_5 = 0$.

Krein inertia at every instant. At each instant Theorem 10.1 applies: while $w^2 > 0$ each eigenspace of $h(x_4)$ has the Krein inertia $(4, 4)$; once $w^2 < 0$ each is Krein-neutral. The wave crosses from the first kind to the second at the onset time. For the band of waves with $q_1 = 0.5$ and $10^{-3} \le q_5 \le 1$ the onset times run from 6.9078 (for $q_5 = 10^{-3}$) down to 0.0941 (for $q_5 = 1$): as time goes on, smaller and smaller extra-time momenta cross into the growing, Krein-neutral regime, and only the good sector keeps real frequencies for ever.

The good sector along the history. For $q_5 = 0$ the mode Hamiltonian is Hermitian and commutes with B at every time, with the energies

$$\pm E(x_4), \qquad E(x_4) = \sqrt{m^2 + k_1^2} = \sqrt{m^2 + q_1^2 e^{-2AHx_4 - 2Hy}},$$

which fall towards m as 3-space inflates. At each instant the positive Fock space of Section 10.20 can be built with the coefficients of that instant (an **instantaneous** Fock space): the filled sea has the value $-8E(x_4)$, and every particle and antiparticle the energy $+E(x_4) > 0$. For example, for $q_1 = 1$ and $y = 0$, $E = \sqrt{2} = 1.414214$ at $a_{4,0} = 0$ and $E = \sqrt{1 + e^{-4}} = 1.009116$ at $a_{4,0} = 2$. Whether the instantaneous vacuum of one time contains quanta of a later time (the evolution of the quantum state through the changing background) is not computed: OPEN.

The universes of masses $+m$ and $-m$ along the history. At every instant $\Gamma h_m(x_4)\Gamma = h_{-m}(x_4)$ (Section 10.6; Γ anticommutes with $\gamma^{(x_4)}$ and commutes with $\gamma^{(x_4)}\gamma^{(x_1)}$ and $\gamma^{(x_4)}\gamma^{(x_5)}$), and w^2 contains the mass only as m^2: the two universes have the same frequencies, the same onset times and the same Krein inertia at every instant.

statement	status	where it is verified

statement	status	where it is verified
evolution of the quantum state through the background; a positive state space for the extra-time sector	OPEN	not computed in the Revision record

10.40 Example: Notebook 10f follows the Krein structure along the deflating history

Notebook 10f reads the history and the scale factors from the Revision records, proves the identities of Section 10.39 exactly for every instant, compares the sizes of h_A and $Bh - hB$ with k_5 and $2k_5$, computes the onset time and checks it against a numerical root search for 48 waves, places the record's sample $k_5 = 2$ at $x_4 = \ln 40$, follows the eigenvalues and the Krein inertia of one wave through its onset, maps which waves still oscillate at which time, builds the instantaneous good-sector Fock space at the five slices of the Kohn-Sham record, and checks the masses $+m$ and $-m$ at every time. It draws five figures and ends with the line ALL 19 CHECKS PASSED (notebook 10f).

10.41 How to run Notebook 10f

Step 1. What this notebook does and what it needs.

Notebook 10f (The Krein structure along the deflating history) is the file `Revision/textbook/notebooks/10f_krein_along_history.ipynb` of the repository Dirac_claude. Along the prescribed deflating history a4 = A H x4 of the Revision Kohn-Sham record (A = H = m = 1) it takes the scale factors of the author's metric from the Revision theory record, turns the coordinate momenta of a wave along x1 and along the extra time x5 into frame momenta (the extra-time one grows like e to the a4 because the extra times deflate), proves exactly that the local mode Hamiltonian of every instant squares to w(x4)^2 times the identity and that its departure from Hermiticity and its mixing of the two sectors of B grow like e to the a4, computes the exact time at which a wave turns from oscillation to growth, follows the eigenvalues and the Krein inertia of the eigenspaces through that time ((4, 4) before, Krein-neutral after), maps which waves are still of real frequency at each time, shows that the good sector keeps a Hermitian mode Hamiltonian, the Krein inertia (4, 4) and a positive instantaneous energy at every time, checks that the masses +m and -m have the same onset, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs

the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is

changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10f_krein_along_history.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10f_krein_along_history.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10f_krein_along_history.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10f.captions.json`

- `Revision/textbook/figures/10f_1_hermiticity_defect.png`
- `Revision/textbook/figures/10f_2_eigenvalues_along_history.png`
- `Revision/textbook/figures/10f_3_inertia_along_history.png`
- `Revision/textbook/figures/10f_4_onset_map.png`
- `Revision/textbook/figures/10f_5_good_sector_energies.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10f_5_good_sector_energies.png exists
ALL 19 CHECKS PASSED (notebook 10f)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10f_krein_along_history.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10f_krein_along_history.ipynb
python -m nbconvert --execute --inplace 10f_krein_along_history.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.42 Notebook 10f: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10f_krein_along_history.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The earlier notebooks of this chapter studied one wave of dirac16complex with
momenta that do not change. In the author's metric they DO change: the three extra
times $x_5, x_6, x_7$ deflate exponentially (their scale factor is
$e^{-a_4}\sin^{1/6}z$, with $a_4$ increasing), and 3-space inflates (scale factor
```

$e^{a_4}\sin^{1/6}z$). A wave with a fixed coordinate momentum along an extra time therefore has a frame momentum that GROWS like e^{a_4}. This notebook follows the quantum structure of the chapter along the deflating history $a_4 = AHx_4$ of the Revision Kohn-Sham record. It

- reads the scale factors from the Revision theory record and turns coordinate momenta into frame momenta;
- proves exactly that the mode Hamiltonian $h(x_4)$ of every instant satisfies $h(x_4)^2 = w(x_4)^2I_{16}$, and that its departure from Hermiticity and its mixing of the two eigenspaces of B both grow like e^{a_4};
- computes the exact time at which a wave with extra-time momentum turns from oscillation into growth, and shows that EVERY such wave reaches it;
- follows the eigenvalues and the Krein inertia of the eigenspaces through that time: inertia $(4, 4)$ before, Krein-neutral after;
- maps, for a whole range of extra-time momenta, which waves still have a real frequency at each time;
- shows that the good sector (no extra-time momentum) keeps a Hermitian mode Hamiltonian, the inertia $(4, 4)$ and a positive energy for every quantum at every time, with an energy that falls towards m as 3-space inflates;
- checks that the masses $+m$ and $-m$ have the same onset of growth;
- draws five teaching figures.

Status of the inputs: the history $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND (it is not solved from the field equations for a_4), and every statement here is made in the *local-frame model*: at each instant the coefficients of the wave equation are evaluated at that instant and at one hidden position, as the Revision record does for its statement that every extra-time mode eventually grows.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 10f (The Krein structure along the deflating history) is the file ‘Revision/textbook/notebooks/10f_krein_along_history.ipynb‘ of the repository Dirac_claude. Along the prescribed deflating history a4 = A H x4 of the Revision Kohn-Sham record (A = H = m = 1) it takes the scale factors of the author’s metric from the Revision theory record, turns the coordinate momenta of a wave along x1 and along the extra time x5 into frame momenta (the extra-time one grows like e to the a4 because the extra times deflate), proves exactly that the local mode Hamiltonian of every instant squares to w(x4)^2 times the identity and that its departure from Hermiticity and its mixing of the two sectors of B grow like e to the a4, computes the exact time at which a wave turns from oscillation to growth, follows the eigenvalues and the Krein inertia of the eigenspaces through that time ((4, 4) before, Krein-neutral after), maps which waves are still of real frequency at each time, shows that the good sector keeps a Hermitian mode Hamiltonian, the Krein inertia (4, 4) and a positive instantaneous energy at every time, checks that the masses +m and -m have the same onset, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy

and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already

active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10f_krein_along_history.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10f_krein_along_history.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10f_krein_along_history.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10f.captions.json‘
- ‘Revision/textbook/figures/10f_1_hermiticity_defect.png‘
- ‘Revision/textbook/figures/10f_2_eigenvalues_along_history.png‘
- ‘Revision/textbook/figures/10f_3_inertia_along_history.png‘
- ‘Revision/textbook/figures/10f_4_onset_map.png‘
- ‘Revision/textbook/figures/10f_5_good_sector_energies.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10f_5_good_sector_energies.png exists
ALL 19 CHECKS PASSED (notebook 10f)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10f_krein_along_history.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
    python -m jupyterlab 10f_krein_along_history.ipynb
    python -m nbconvert --execute --inplace 10f_krein_along_history.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
  the Revision record: the data it starts from and the report files whose checks it
  reproduces (each cited check must still exist there with the verdict PASS). It must be
  opened inside the folder Revision/textbook/notebooks of a complete copy of the
  repository (a notebook copied alone to another folder cannot find them). Clone the
  repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the
  Revision record no longer holds the check that the notebook names, or holds it with
  another verdict: the copy of the repository is incomplete or was changed. Clone the
  repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 10f (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10f (The Krein structure along the deflating history) is the file
# Revision/textbook/notebooks/10f_krein_along_history.ipynb of the repository
# Dirac_claude. Along the prescribed deflating history a4 = A H x4 of the Revision
# Kohn-Sham record (A = H = m = 1) it takes the scale factors of the author’s metric from
# the Revision theory record, turns the coordinate momenta of a wave along x1 and along
# the extra time x5 into frame momenta (the extra-time one grows like e to the a4 because
# the extra times deflate), proves exactly that the local mode Hamiltonian of every
# instant squares to w(x4)^2 times the identity and that its departure from Hermiticity
# and its mixing of the two sectors of B grow like e to the a4, computes the exact time
# at which a wave turns from oscillation to growth, follows the eigenvalues and the Krein
# inertia of the eigenspaces through that time ((4, 4) before, Krein-neutral after), maps
# which waves are still of real frequency at each time, shows that the good sector keeps
# a Hermitian mode Hamiltonian, the Krein inertia (4, 4) and a positive instantaneous
# energy at every time, checks that the masses +m and -m have the same onset, and draws
# five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
```

```
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
# shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
```

```
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10f_krein_along_history.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10f_krein_along_history.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10f_krein_along_history.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10f.captions.json
# - Revision/textbook/figures/10f_1_hermiticity_defect.png
# - Revision/textbook/figures/10f_2_eigenvalues_along_history.png
# - Revision/textbook/figures/10f_3_inertia_along_history.png
# - Revision/textbook/figures/10f_4_onset_map.png
# - Revision/textbook/figures/10f_5_good_sector_energies.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
```

```
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10f_5_good_sector_energies.png exists
#     ALL 19 CHECKS PASSED (notebook 10f)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10f_krein_along_history.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10f_krein_along_history.ipynb
#     python -m nbconvert --execute --inplace 10f_krein_along_history.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
```

```
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
#

## 3. The words used in this notebook

- **Scale factor** $f_a$: the factor by which the author's metric stretches the
  coordinate $x_a$; a coordinate distance $dx_a$ has the proper length $f_a\,dx_a$.
  For 3-space $f = e^{a_4}\sin^{1/6}z$, for the extra times $f = e^{-a_4}
  \sin^{1/6}z$.
- **Deflating history**: the time dependence $a_4 = AHx_4$ with $A = 1$; as $x_4$
  grows, 3-space inflates and the extra times deflate, both exponentially.
- **Coordinate momentum** $q_a$ and **frame momentum** $k_a$: a wave $e^{iq_ax_a}$
  has the coordinate momentum $q_a$; measured with proper lengths its momentum is
  $k_a = q_a/f_a$, the frame momentum.
- **Hidden position** $y$: the Kohn-Sham record measures the hidden direction by
  $y = \ln(\sin z)/(6H)$, so that $\sin^{1/6}z = e^{Hy}$; the patch end
  $z = \pi/2$ is $y = 0$, and $y < 0$ lies towards the tip.
- **Local-frame model**: at the instant $x_4$ and the position $y$ the wave equation
  is written with the coefficients of that instant and that position; the
  hidden-direction terms (studied in the notebook on the curved good sector) are
  left out.
- **Mode Hamiltonian** $h$: the $16 \times 16$ matrix with $i\,du/dx_4 = hu$; its
  eigenvalues $\pm w$ are the frequencies.
- **Onset time** $x_4^\ast$: the time at which $w^2$ changes from positive (the wave
  oscillates) to negative (the wave grows).
```

```
- **Hermitian part, anti-Hermitian part**: every matrix is $h = h_H + h_A$ with
  $h_H = \frac12(h + h^\dagger)$ Hermitian and $h_A = \frac12(h - h^\dagger)$
  anti-Hermitian ($h_A^\dagger = -h_A$).
- **Size of a matrix (spectral norm)**: the largest factor by which the matrix
  stretches the length of a column; in code `np.linalg.norm(M, 2)`.
- **Krein inertia, Krein-neutral**: as in the first notebook of this chapter, the
  numbers of positive, negative and zero eigenvalues of the Krein form $u^\dagger Bv$
  on a subspace; neutral means that the form vanishes on it.
- **Good sector**: waves without extra-time momentum, $q_5 = q_6 = q_7 = 0$.
- **Instantaneous**: computed with the coefficients of one instant, as if they did
  not change.
```

Text cell:

```
## 4. The physical and mathematical situation

**The wave equation of one instant, line by line.** The field equation of
dirac16complex in the author's metric (Revision theory record, $U = 0$) is

$$e^{-a_4}\sin^{-1/6}z\sum_{i=1}^{3}\gamma^{(x_i)}\partial_i\Psi + \gamma^{(x_4)}
\partial_4\Psi + e^{a_4}\sin^{-1/6}z\sum_{t=5}^{7}\gamma^{(x_t)}\partial_t\Psi +
\tan z\,\gamma^{(x_0)}\partial_0\Psi + 3H\gamma^{(x_0)}\Psi = m\Psi .$$

Each derivative $\partial_a$ is divided by the scale factor $f_a$ of its direction.
In the local-frame model take a wave $\Psi = u(x_4)\,e^{i(q_1x_1 + q_5x_5)}$ at one
hidden position and leave out the two hidden-direction terms. Then $\partial_1$
becomes $iq_1$ and $\partial_5$ becomes $iq_5$:

$$i k_1\gamma^{(x_1)}u + \gamma^{(x_4)}\frac{du}{dx_4} + ik_5\gamma^{(x_5)}u = mu,
\qquad k_1 = q_1e^{-a_4}\sin^{-1/6}z,\qquad k_5 = q_5e^{a_4}\sin^{-1/6}z .$$

Multiply from the left by $\gamma^{(x_4)}$, use $(\gamma^{(x_4)})^2 = -1$, solve for
$du/dx_4$ and multiply by $i$ (exactly the steps of the first notebook of this
chapter):

$$i\frac{du}{dx_4} = h(x_4)\,u,\qquad h(x_4) = -im\gamma^{(x_4)} -
k_1(x_4)\,\gamma^{(x_4)}\gamma^{(x_1)} - k_5(x_4)\,\gamma^{(x_4)}\gamma^{(x_5)} .$$

With $\sin^{1/6}z = e^{Hy}$ and $a_4 = AHx_4$ the frame momenta are
$k_1 = q_1e^{-AHx_4 - Hy}$, which SHRINKS (3-space inflates), and
$k_5 = q_5e^{AHx_4 - Hy}$, which GROWS (the extra times deflate).

**The squared frequency.** By the identity $h^2 = w^2I_{16}$ of the first notebook
of this chapter, at every instant

$$w(x_4)^2 = m^2 + k_1^2 - k_5^2 = m^2 + q_1^2e^{-2AHx_4 - 2Hy} -
q_5^2e^{2AHx_4 - 2Hy} .$$

For $A > 0$ the second term falls and the third grows in size, so $w^2$ falls all
the time; if $q_5 \neq 0$ it becomes negative after a finite time.

**The onset time, line by line.** Write $X = e^{2AHx_4} > 0$ and $c = e^{-2Hy}$.
The condition $w^2 = 0$ reads $m^2 + q_1^2c/X - q_5^2cX = 0$. Multiply by $X$:
```

```
$$q_5^2c\,X^2 - m^2X - q_1^2c = 0 .$$

This is a quadratic equation for $X$; its only positive root is

$$X^\ast = \frac{m^2 + \sqrt{m^4 + 4q_1^2q_5^2c^2}}{2q_5^2c},\qquad
x_4^\ast = \frac{\ln X^\ast}{2AH} .$$

(The other root has the minus sign in front of the square root; it is negative, or
zero when $q_1 = 0$, because the square root is at least $m^2$, while
$X = e^{2AHx_4}$ is always positive.) For $q_1 = 0$ and $y = 0$ this is
$X^\ast = m^2/q_5^2$, so $x_4^\ast = \ln(m/q_5)/(AH)$: the onset comes when the
growing frame momentum $k_5$ reaches the mass.

**Hermitian and anti-Hermitian parts.** The matrices $-i\gamma^{(x_4)}$ and
$\gamma^{(x_4)}\gamma^{(x_1)}$ are Hermitian and commute with $B$, while
$\gamma^{(x_4)}\gamma^{(x_5)}$ is anti-Hermitian and anticommutes with $B$ (first
notebook of this chapter). Hence $h_A = -k_5\gamma^{(x_4)}\gamma^{(x_5)}$, and since
$(\gamma^{(x_4)}\gamma^{(x_5)})^2 = -(\gamma^{(x_4)})^2(\gamma^{(x_5)})^2 = -I$,

$$h_A^\dagger h_A = -h_A^2 = k_5^2 I_{16} .$$

So $h_A$ stretches every column by exactly the factor $k_5$: the size of the
anti-Hermitian part is $k_5 = q_5e^{AHx_4 - Hy}$. In the same way
$Bh - hB = 2Bh_A$ has the size $2k_5$ ($B$ keeps lengths, because $B^\dagger B =
B^2 = I$). Both grow exponentially with the deflation; both vanish at every time in
the good sector, $q_5 = 0$.

**Krein inertia at each instant.** At each instant $h(x_4)$ is the mode Hamiltonian
of the first notebook of this chapter with real frame momenta, so the Revision
proof applies instant by instant: while $w^2 > 0$ each eigenspace has Krein inertia
$(4, 4)$; once $w^2 < 0$ each eigenspace is Krein-neutral.
```

Text cell:

```
## 5. The deflating history of the Revision record

The next cell reads the parameters of the Revision Kohn-Sham record: the constant
$H$, the mass $m$, the history constant $A$ and the five slices $a_{4,0}$ at which
that record computes its instantaneous Kohn-Sham states. It prints the first
sentence of the record's own statement of the status of the history and checks the
values $A = H = m = 1$. It also defines ‘check_record‘ (the PASS line and the line
naming the reproduced Revision record are printed in one piece, because Jupyter
sends printed text to the screen in pieces whose boundaries depend on timing) and
the colours of the figures.
Before it checks anything, ‘check_record‘ asks the helper ‘record_says_pass‘ whether
the cited record still says PASS: for a record name of the form
‘<report file>, check <check name>‘ it opens that report (each file once, kept in
the dictionary ‘REPORT_CHECKS‘) and stops the notebook with an error unless a check
of that name exists there with the verdict PASS; a record name without ‘, check ‘
names a data entry that the notebook reads and compares itself.
```

In [2]:

## 6. Frame momenta from the scale factors of the record

The Revision theory record ‘Revision/theory/field-theory.json‘ stores the scale
factors $f_a$ of the eight directions (formula key ‘vielbein_diagonal‘) in the
notation of the Wolfram Language, for example ‘E^a4[x4]*Sin[6*H*x0]^(1/6)‘. The
next cell translates this text into sympy (‘E^a4[x4]‘ becomes ‘exp(a4)‘,
‘Sin[6*H*x0]‘ becomes ‘sin(z)‘, ‘^‘ becomes ‘**‘, curly brackets become square
brackets), and checks EXACTLY that it equals $e^{a_4}\sin^{1/6}z$ for $x_1, x_2,
x_3$, 1 for $x_4$, $e^{-a_4}\sin^{1/6}z$ for the extra times and $\cot z$ for
$x_0$. Then it defines the frame momenta $k_1 = q_1/f_1$ and $k_5 = q_5/f_5$ at
the time $x_4$ and the hidden position $y$ (with $\sin^{1/6}z = e^{Hy}$).
```

In [3]:

```
theory = json.loads(repository_file("Revision/theory/field-theory.json").read_text(
    encoding="utf-8"))
text = next(f["wl"] for f in theory["formulas"] if f["key"] == "vielbein_diagonal")
a4_symbol, z_symbol = sp.symbols("a4 z", real=True)
translated = (text.replace("E^a4[x4]", "exp(a4)").replace("Sin[6*H*x0]", "sin(z)")
              .replace("Cot[6*H*x0]", "cot(z)").replace("^", "**")
              .replace("{", "[").replace("}", "]"))
f_record = sp.sympify(translated, locals={"a4": a4_symbol, "z": z_symbol})
sixth_root = sp.sin(z_symbol) ** sp.Rational(1, 6)  # sin(z)^(1/6)
f_expected = ([sp.cot(z_symbol)] + [sp.exp(a4_symbol) * sixth_root] * 3
              + [sp.Integer(1)] + [sp.exp(-a4_symbol) * sixth_root] * 3)  # x0, ..., x7
same = all(sp.simplify(r - e) == 0 for r, e in zip(f_record, f_expected))
say(f"scale factor of x1: {f_record[1]}")
say(f"scale factor of x5: {f_record[5]}")
check_record(len(f_record) == 8 and same,
             "the record's scale factors: e^a4 sin^(1/6) z (3-space), e^-a4 ... (x5-x7)",

## 7. The mode Hamiltonian of each instant, exactly

The next cell reads the gammas, builds $B$ and the chirality $\Gamma$, and defines
the mode Hamiltonian `mode_hamiltonian(x4, q1, q5, y, m)` of Section 4 as a numpy
matrix. Then it repeats the algebra of Section 4 EXACTLY with sympy, with symbols
for $m$, $q_1$, $q_5$, $H$, $y$ and the time $x_4$ (so the statements hold at every
instant and every position):

- $h(x_4)^2 = (m^2 + q_1^2e^{-2a_4 - 2Hy} - q_5^2e^{2a_4 - 2Hy})I_{16}$;
- the anti-Hermitian part is $h_A = -k_5\gamma^{(x_4)}\gamma^{(x_5)}$ and
  $h_A^\dagger h_A = k_5^2I_{16}$;
- $Bh - hB = 2Bh_A$;
- in the good sector ($q_5 = 0$) $h$ is Hermitian and commutes with $B$ at every
  time.
```

## 9. One wave through the onset: eigenvalues and Krein inertia

The next cell defines the exact onset time of Section 4 and checks it against a
numerical root search for 48 waves (four values of $q_1$, four of $q_5$, three hidden
positions $y$). The search is *bisection*: start with an interval of times in which
$w^2$ changes sign and halve it 200 times, always keeping the half in which the sign
changes. It also checks the short form $x_4^\ast = \ln(m/q_5)$ for $q_1 = 0$,
$y = 0$.
```

In [6]:

## 10. Every extra-time wave becomes Krein-neutral: the onset map

For $q_1 = 0.5$ and $y = 0$, the next cell computes the sign of $w^2$ on a grid of
241 times from 0 to 6 and 121 extra-time momenta $q_5$ from $10^{-3}$ to 1 (equally
spaced in $\log_{10} q_5$), checks that the sign agrees everywhere with the exact
onset time ($w^2 > 0$ exactly when $x_4 < x_4^\ast(q_5)$), computes the Krein
inertia directly at the grid points of every fourth momentum and every 60th time
(skipping those closer than 0.05 to the onset), and draws the map with the
onset curve and the five slices $a_{4,0}$ of the Kohn-Sham record. For every
$q_5 > 0$ the onset time is finite: no wave with extra-time momentum keeps a real
frequency for ever.
```

In [10]:

```
map_times = np.linspace(0.0, 6.0, 241)
exponents = np.linspace(-3.0, 0.0, 121)  # log10 of q5
q5_values = 10.0 ** exponents
real_frequency = np.array([[w_squared(x4, 0.5, q5, 0.0) > 0 for x4 in map_times]
                           for q5 in q5_values])  # rows: q5, columns: x4
onsets = np.array([onset_time(0.5, q5, 0.0) for q5 in q5_values])
agree = np.array_equal(real_frequency, map_times[None, :] < onsets[:, None])
```

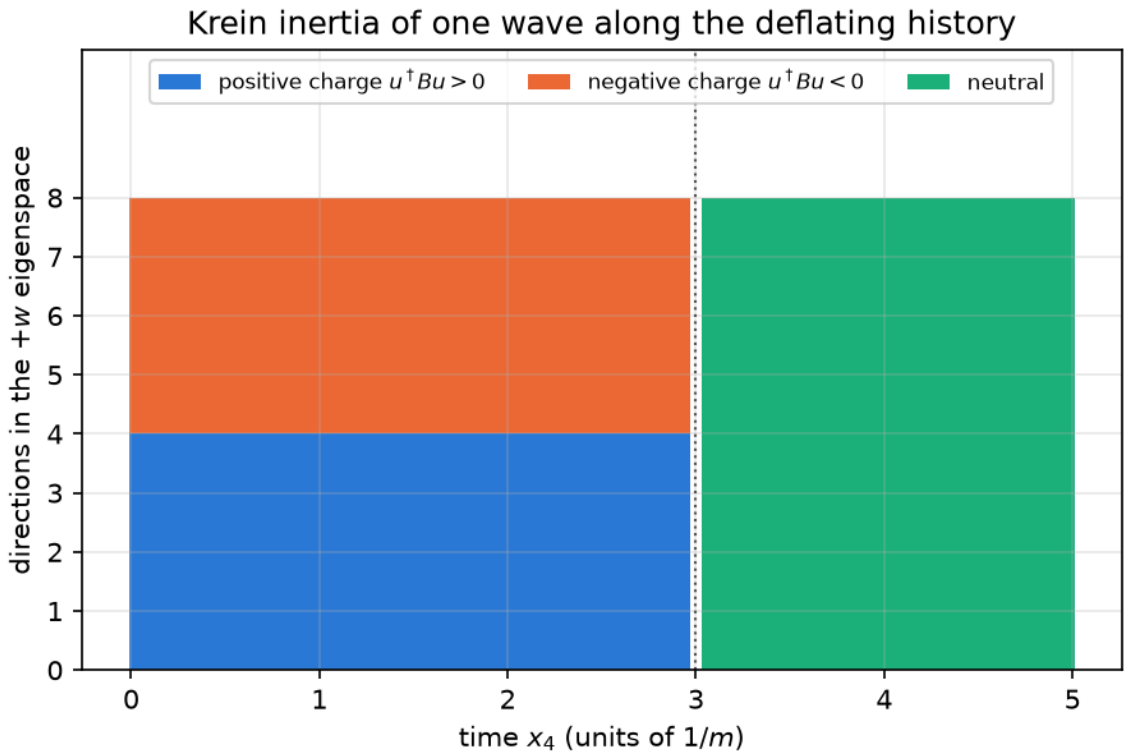

Figure 295: The Krein inertia of the eigenspace of $+w$ of the mode Hamiltonian of the wave $q_1 = 0.5$, $q_5 = 0.05$ ($y = 0$) at each time x_4 of the deflating history $a_4 = x_4$ (horizontal axis, units of $1/m$). Each thin bar splits the eight directions of the eigenspace (vertical axis) into positive charge (blue), negative charge (orange) and neutral (green). Before the onset time $x_4^* = 2.996$ (dotted line) the split is 4 and 4 at every instant; after it the whole eigenspace is neutral. The deflation of the extra times moves the wave from the first kind to the second at a definite time. (Notebook 10f, figure 3.)

## 11. The good sector along the history

In the good sector ($q_5 = 0$) the mode Hamiltonian of every instant is Hermitian
and commutes with $B$ (Section 7), with the energies $\pm E(x_4)$,
```

```
$$E(x_4) = \sqrt{m^2 + k_1^2} = \sqrt{m^2 + q_1^2e^{-2AHx_4 - 2Hy}},$$

which falls towards $m$ as 3-space inflates and its frame momentum shrinks. At each
instant the positive Fock space of the previous notebooks can be built with the
coefficients of that instant (an *instantaneous* Fock space): the filled sea has the
value $\sum_s v_s^\dagger hv_s = -8E(x_4)$, and a particle and an antiparticle have
the normal-ordered energies $u_s^\dagger hu_s = +E(x_4)$ and $-v_s^\dagger hv_s =
+E(x_4)$. The next cell checks, at the five slices of the Kohn-Sham record and for
four momenta $q_1 = 0.5, 1, 2, 4$ ($y = 0$): $h$ Hermitian, $Bh = hB$, eight
eigenvalues $+E$ and eight $-E$, the Krein inertia $(4, 4)$ of both eigenspaces, the
sea value $-8E$ and the quantum energies $+E$. Then it draws $E(x_4)$ and the sea
value.
```

## 12. The universes of masses $+m$ and $-m$ along the history

At every instant the mode Hamiltonian of the history is a mode Hamiltonian of the
first notebook of this chapter, so the identity $\Gamma h_m\Gamma = h_{-m}$ of the
Revision pairing record holds at every time ($\Gamma$ anticommutes with
$\gamma^{(x_4)}$ and commutes with $\gamma^{(x_4)}\gamma^{(x_1)}$ and
$\gamma^{(x_4)}\gamma^{(x_5)}$). The mass enters $w^2$ only as $m^2$, so the two
```

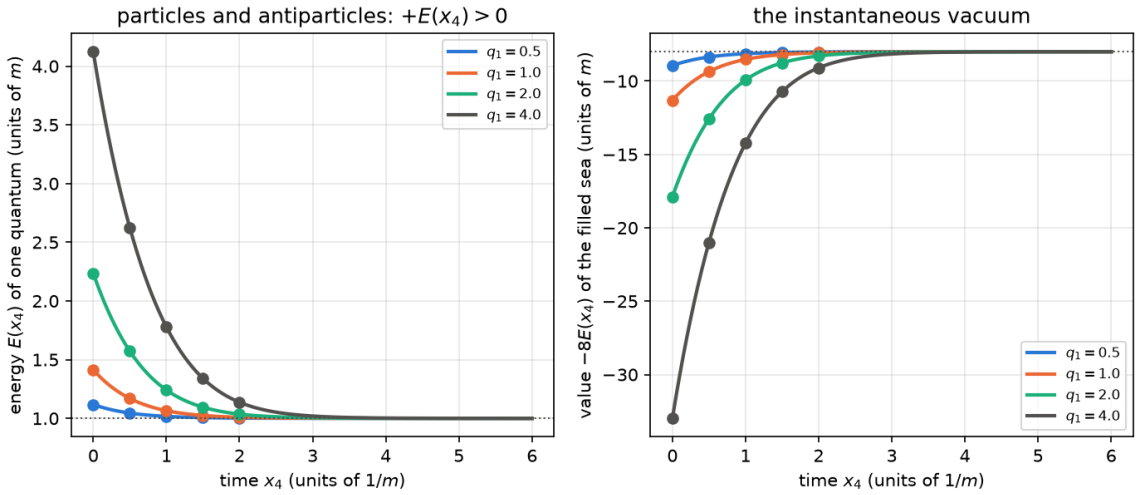

Figure 297: The good sector along the deflating history $a_4 = x_4$ ($A = H = m = 1$, $y = 0$) for the coordinate momenta $q_1 = 0.5$, 1, 2, 4 (blue, orange, green, grey); horizontal axes: the time x_4 in units of $1/m$. Left: the normal-ordered energy $E(x_4) = \sqrt{m^2 + q_1^2 e^{-2x_4}}$ of one particle or one antiparticle of the instantaneous Fock space, falling towards the mass m (dotted line) as 3-space inflates; right: the value $-8E(x_4)$ of the filled sea, rising towards $-8m$ (dotted line). Vertical axes in units of m. Dots: computed from the eigenvectors at the five slices of the Kohn-Sham record. In the good sector every quantum has a positive energy at every time, and the Krein inertia stays (4, 4). (Notebook 10f, figure 5.)

```
universes have the same frequencies, the same onset time and the same Krein inertia
at every instant. The next cell checks the identity at 25 times for the wave
$q_1 = 0.5$, $q_5 = 0.05$, and that the eigenvalues for $+m$ and $-m$ agree.

## 14. What this notebook showed

- REPRODUCED from the Revision records: the deflating history $a_4 = AHx_4$ with
  $A = H = m = 1$ and its status, and the scale factors of the author's metric; a
  wave $e^{i(q_1x_1 + q_5x_5)}$ has the frame momenta $k_1 = q_1e^{-a_4}
  \sin^{-1/6}z$ (shrinking: 3-space inflates) and $k_5 = q_5e^{a_4}\sin^{-1/6}z$
  (growing: the extra times deflate).
- PROVED (exactly, at every instant of the local-frame model): $h(x_4)^2 =
  w(x_4)^2I_{16}$ with $w^2 = m^2 + k_1^2 - k_5^2$; the anti-Hermitian part of
  $h(x_4)$ has the size $k_5$ and the mixing of the two eigenspaces of $B$ the size
  $2k_5$, both growing like $e^{a_4}$; in the good sector $h(x_4)$ is Hermitian and
  commutes with $B$ at every time.
- PROVED (exactly): every wave with $q_5 \neq 0$ reaches the onset time
  $x_4^\ast = \ln X^\ast/(2AH)$ and grows afterwards. COMPUTED: the onset of the
  wave $q_1 = 0.5$, $q_5 = 0.05$ is $x_4^\ast = 2.996$; the recorded sample $m = 1$,
  $k_5 = 2$ (eigenvalues $\pm i\sqrt3$) is the instant $x_4 = \ln 40$ of the wave
  $q_5 = 0.05$; the Krein inertia is $(4, 4)$ at every instant before the onset and
  the eigenspaces are Krein-neutral at every instant after it; the band of
```

```
  oscillating extra-time waves shrinks exponentially, and only the good sector
  keeps real frequencies for ever.
- COMPUTED (at the five slices of the Kohn-Sham record): in the good sector the
  instantaneous Fock space has the sea value $-8E(x_4)$ and quanta of energy
  $+E(x_4) > 0$, with $E$ falling towards $m$.
- PROVED (at every instant): the masses $+m$ and $-m$ have identical one-particle
  spectra, onset times and Krein inertia.
- ASSUMED: the history $a_4 = AHx_4$ is a prescribed background, not a solution of
  the field equations for $a_4$ with this field as the source; the local-frame model
  evaluates the coefficients at one instant and one hidden position and leaves out
  the hidden-direction terms.
- OPEN (not computed here): the evolution of the quantum state through the changing
  background (whether the instantaneous vacuum of one time contains quanta of a
  later time); a positive state space for the extra-time sector, whose waves all
  become Krein-neutral.
```

10.43 Line-by-line walk-through of Notebook 10f

The notebook has 13 code cells, In [1] to In [13]; docstrings are left out of the quotations (they are printed in Section 10.42).

In [1], the set-up cell. Its first 252 lines are comments that repeat the run instructions of Section 10.41. The code is that of In [1] of Notebook 10a (Section 10.10), with the line `NOTEBOOK_ID = "10f" # this notebook: chapter 10, example f`. It prints `Set-up of notebook 10f complete: repository folder found, helpers defined.`

In [2], the deflating history of the Revision record.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout

import numpy as np  # numbers, arrays and matrices
import sympy as sp  # exact algebra with symbols

REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"

def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
```

```
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output

BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
```

The imports, the helpers `REPORT_CHECKS`, `record_says_pass` and `check_record` of Section 10.10 (a cited report check must still exist with the verdict PASS; the two printed lines come in one piece), and the four colours.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
H = parameters["physics"]["H"]  # the author's constant H
mass = parameters["physics"]["m"]  # the mass m
A = parameters["physics"]["historyA"]  # the history a4 = A H x4
slices = parameters["physics"]["slicesA4"]  # the values a4,0 of the record
```

The parameters of the Kohn-Sham record are read: the constant H, the mass m (called `mass` here, because the letter `m` is kept free), the history constant A and the list of the five slices $a_{4,0}$.

```
say("status of the history: "
    + parameters["conventions"]["history"].split(": ")[0] + ".")
say(f"slices a4,0 of the Kohn-Sham record: {slices}")
check_record(A == 1.0 and H == 1.0 and mass == 1.0,
             "the deflating history a4 = A H x4 with A = 1, H = 1, m = 1",
             record="Revision/kohn_sham/results/parameters.json, physics.historyA, "
                    "physics.H, physics.m")
```

The record states the status of the history in a sentence that begins with `PRESCRIBED BACKGROUND:`; `.split(":  ")` cuts the text at the first colon and blank (and at any later one), and `[0]` keeps the first piece. The printed lines are `status of the history:  PRESCRIBED BACKGROUND.` and the slices `[0.0, 0.5, 1.0, 1.5, 2.0]`; the check confirms $A = H = m = 1$ and reproduces the three entries of the record.

```
def a4_of(x4):
    return A * H * x4
```

`a4_of(x4)` is the prescribed history $a_4 = AHx_4$.

In [3], frame momenta from the scale factors of the record.

```
theory = json.loads(repository_file("Revision/theory/field-theory.json").read_text(
    encoding="utf-8"))
text = next(f["wl"] for f in theory["formulas"] if f["key"] == "vielbein_diagonal")
a4_symbol, z_symbol = sp.symbols("a4 z", real=True)
```

The theory record holds a list of formulas, each a dictionary with a key and the formula as text in the Wolfram Language (entry `wl`). `next(...)` returns the first item of the generator expression in the parentheses: the text of the formula whose key is `vielbein_diagonal`, the eight scale factors. `a4_symbol` and `z_symbol` are two real sympy letters.

```
translated = (text.replace("E^a4[x4]", "exp(a4)").replace("Sin[6*H*x0]", "sin(z)")
              .replace("Cot[6*H*x0]", "cot(z)").replace("^", "**")
              .replace("{", "[").replace("}", "]"))
f_record = sp.sympify(translated, locals={"a4": a4_symbol, "z": z_symbol})
```

The Wolfram text, for example `E^a4[x4]*Sin[6*H*x0]^(1/6)`, is translated step by step into sympy notation: e^{a_4}, $\sin z$ and $\cot z$ are written with the letters a_4 and z, `^` becomes `**` and the curly brackets of a Wolfram list become square brackets. `sp.sympify` reads the text as a list of eight exact expressions; `locals` tells it which letters to use.

```
sixth_root = sp.sin(z_symbol) ** sp.Rational(1, 6)  # sin(z)^(1/6)
f_expected = ([sp.cot(z_symbol)] + [sp.exp(a4_symbol) * sixth_root] * 3
              + [sp.Integer(1)] + [sp.exp(-a4_symbol) * sixth_root] * 3)  # x0, ..., x7
same = all(sp.simplify(r - e) == 0 for r, e in zip(f_record, f_expected))
say(f"scale factor of x1: {f_record[1]}")
say(f"scale factor of x5: {f_record[5]}")
check_record(len(f_record) == 8 and same,
             "the record's scale factors: e^a4 sin^(1/6) z (3-space), e^-a4 ... (x5-x7)",
             record="Revision/theory/field-theory.json, formula vielbein_diagonal")
```

`sp.Rational(1, 6)` is the exact fraction $\frac{1}{6}$. The expected list is built by repeating and joining lists: three times $e^{a_4}\sin^{1/6} z$, then 1, three times $e^{-a_4}\sin^{1/6} z$, then $\cot z$. The comparison simplifies each difference to 0. The printed lines show the scale factors of x_1, `exp(a4)*sin(z)**(1/6)`, and of x_5, `exp(-a4)*sin(z)**(1/6)`: the extra times deflate exponentially as a_4 grows. The check reproduces the record's formula.

```
def frame_momenta(x4, q1, q5, y):
    root = np.exp(H * y)  # sin(z)^(1/6) = e^(H y)
    k1 = q1 / (np.exp(a4_of(x4)) * root)  # q1 / f_1: shrinks, 3-space inflates
    k5 = q5 / (np.exp(-a4_of(x4)) * root)  # q5 / f_5: grows, extra times deflate
    return k1, k5
```

The frame momenta of Section 10.39: $k_1 = q_1/(e^{a_4}e^{Hy})$ and $k_5 = q_5/(e^{-a_4}e^{Hy})$, with $\sin^{1/6} z = e^{Hy}$.

In [4], the mode Hamiltonian of each instant, exactly.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
gamma = {a: np.array(fixture["gamma"][a], dtype=float) for a in range(8)}
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4)
Gamma = (gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5]
         @ gamma[6] @ gamma[7])  # the chirality matrix
```

The gammas of the record as decimal numbers, C, B and the chirality Γ.

```
def mode_hamiltonian(x4, q1, q5, y, m=mass):
    k1, k5 = frame_momenta(x4, q1, q5, y)
    return (-1j * m * gamma[4] - k1 * (gamma[4] @ gamma[1])
            - k5 * (gamma[4] @ gamma[5]))

def w_squared(x4, q1, q5, y, m=mass):
    k1, k5 = frame_momenta(x4, q1, q5, y)
    return m ** 2 + k1 ** 2 - k5 ** 2
```

The mode Hamiltonian $h(x_4)$ of Section 10.39 and its squared frequency $w^2 = m^2 + k_1^2 - k_5^2$. The argument `m=mass` has a **default value**: when the call does not name `m`, the mass of the record is used.

```
g = {a: sp.Matrix(fixture["gamma"][a]) for a in range(8)}  # exact gammas
B_exact = -sp.I * g[0] * g[1] * g[2] * g[3] * g[4]
m_s, q1_s, q5_s, y_s = sp.symbols("m q1 q5 y", real=True)
x4_s, H_s = sp.symbols("x4 H", positive=True)
a4_s = A * H_s * x4_s  # the history, with the record's A = 1
k1_s = q1_s * sp.exp(-a4_s - H_s * y_s)  # frame momentum along x1
k5_s = q5_s * sp.exp(a4_s - H_s * y_s)  # frame momentum along x5
h_s = -sp.I * m_s * g[4] - k1_s * g[4] * g[1] - k5_s * g[4] * g[5]
zero = sp.zeros(16, 16)
```

The same objects exactly: letters for m, q_1, q_5, y (real) and x_4, H (positive), the history, the frame momenta $k_1 = q_1 e^{-a_4 - Hy}$ and $k_5 = q_5 e^{a_4 - Hy}$, and the exact $h(x_4)$. A statement about these letters holds at every instant and every position.

```
w2_s = m_s ** 2 + k1_s ** 2 - k5_s ** 2
square_ok = (h_s * h_s - w2_s * sp.eye(16)).applyfunc(sp.expand) == zero
h_A = ((h_s - h_s.H) / 2).applyfunc(sp.expand)  # the anti-Hermitian part
part_ok = (h_A + k5_s * g[4] * g[5]).applyfunc(sp.expand) == zero
size_ok = (h_A.H * h_A - k5_s ** 2 * sp.eye(16)).applyfunc(sp.expand) == zero
mixing_ok = (B_exact * h_s - h_s * B_exact - 2 * B_exact * h_A).applyfunc(
    sp.expand) == zero
```

The identities of Section 10.39: $h^2 = w^2 I_{16}$; the anti-Hermitian part $h_A = \frac{1}{2}(h - h^\dagger)$ equals $-k_5 \gamma^{(x_4)} \gamma^{(x_5)}$; $h_A^\dagger h_A = k_5^2 I_{16}$; and $Bh - hB = 2Bh_A$.

```
good = h_s.subs(q5_s, 0)  # the good sector
good_ok = ((good - good.H).applyfunc(sp.expand) == zero
           and (B_exact * good - good * B_exact).applyfunc(sp.expand) == zero)
check(square_ok, "exact: h(x4)^2 = (m^2 + k1^2 - k5^2) I at every instant")
check(part_ok and size_ok and mixing_ok,
      "exact: h_A = -k5 g4 g5, h_A^dagger h_A = k5^2 I, B h - h B = 2 B h_A")
check_record(good_ok,
             "exact: good sector, h(x4) Hermitian and commuting with B at all times",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_spectrum_and_B_sectors")
```

With $q_5 = 0$ the matrix must be Hermitian and commute with B at all times. Three PASS lines; the third reproduces the record check `good_sector_spectrum_and_B_sectors`.

In [5], the departure from Hermiticity and the mixing of the two sectors of B.

```
times = np.linspace(0.0, 6.0, 13)  # 0, 0.5, ..., 6
curve_times = np.linspace(0.0, 6.0, 241)
measured, worst = {}, 0.0
for q5 in (0.01, 0.05, 0.2):
    sizes = []
    for x4 in times:
        h = mode_hamiltonian(x4, 0.5, q5, 0.0)
        h_anti = (h - h.conj().T) / 2
        sizes.append((np.linalg.norm(h_anti, 2), np.linalg.norm(B @ h - h @ B, 2)))
```

For three extra-time momenta $q_5 = 0.01, 0.05, 0.2$ (with $q_1 = 0.5$ and $y = 0$) and 13 times from 0 to 6, the cell measures the size of the anti-Hermitian part and of the commutator $Bh - hB$; `np.linalg.norm(M, 2)` is the size of a matrix (its largest stretching factor).

```
        k5 = frame_momenta(x4, 0.5, q5, 0.0)[1]
        worst = max(worst, abs(sizes[-1][0] - k5) / k5,
                    abs(sizes[-1][1] - 2 * k5) / (2 * k5))
    measured[q5] = np.array(sizes)
good_sizes = [np.linalg.norm(mode_hamiltonian(x4, 0.5, 0.0, 0.0)
                             - mode_hamiltonian(x4, 0.5, 0.0, 0.0).conj().T, 2)
              for x4 in times]
report("largest relative difference from k5 and 2 k5", f"{worst:.1e}")
check(worst < 1e-12 and max(good_sizes) == 0.0,
      "sizes of h_A and of B h - h B are k5 = q5 e^a4 and 2 k5; zero if q5 = 0")
```

The measured sizes are compared with k_5 and $2k_5$ (`sizes[-1]` is the pair just appended; `[1]` of the frame momenta is k_5), and in the good sector the size of $h - h^\dagger$ must be exactly 0 at every time. The largest relative difference is printed as `0.0e+00`.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharey=True)
for q5, colour in ((0.01, BLUE), (0.05, ORANGE), (0.2, GREEN)):
    k5_curve = frame_momenta(curve_times, 0.5, q5, 0.0)[1]
    axes[0].plot(curve_times, k5_curve, color=colour, linewidth=2,
                 label=f"$q_5 = {q5}$")
    axes[0].plot(times, measured[q5][:, 0], "o", color=colour, markersize=5)
    axes[1].plot(curve_times, 2 * k5_curve, color=colour, linewidth=2,
                 label=f"$q_5 = {q5}$")
    axes[1].plot(times, measured[q5][:, 1], "o", color=colour, markersize=5)
```

For each q_5 the formulas k_5 and $2k_5$ are drawn as lines (`frame_momenta` works on the whole array of 241 times at once) and the measured sizes as dots.

```
for ax in axes:
    ax.set_yscale("log")
```

```
    ax.axhline(mass, color=GREY, linestyle=":", linewidth=1)
    ax.set_xlabel("time $x_4$ (units of $1/m$)")
    ax.legend(loc="lower right", fontsize=8)
axes[0].set_ylabel("size (units of $m$)")
axes[0].set_title("anti-Hermitian part $h_A$: size $k_5 = q_5e^{a_4}$")
axes[1].set_title("mixing of the $B$ sectors: size of $Bh - hB$")
save_figure(fig, "hermiticity_defect",
...)
```

Logarithmic vertical axes (`set_yscale("log")`), on which an exponential is a straight line, and a dotted line at the mass. Figure 1 of Notebook 10f shows three parallel straight lines in each panel with the dots on them: the departure from Hermiticity and the mixing of the two sectors of B grow like e^{a_4}, crossing the level of the mass sooner for larger q_5.

In [6], the exact onset time.

```
def onset_time(q1, q5, y):
    c = np.exp(-2 * H * y)
    X = (mass ** 2 + np.sqrt(mass ** 4 + 4 * q1 ** 2 * q5 ** 2 * c ** 2)) / (
        2 * q5 ** 2 * c)
    return np.log(X) / (2 * A * H)
```

The formula $x_4^* = \ln X^*/(2AH)$ of Section 10.39, with $c = e^{-2Hy}$.

```
def bisection(q1, q5, y, low=-40.0, high=40.0):
    for _ in range(200):
        middle = (low + high) / 2
        if w_squared(middle, q1, q5, y) > 0:  # still oscillating: the onset is later
            low = middle
        else:
            high = middle
    return (low + high) / 2
```

An independent numerical root search, **bisection**: the interval from -40 to 40 contains the onset; at its midpoint, if $w^2 > 0$ the wave still oscillates and the onset lies in the right half, otherwise in the left half; halving 200 times shrinks the interval far below the rounding level, and its midpoint is returned.

```
worst = max(abs(onset_time(q1, q5, y) - bisection(q1, q5, y))
            for q1 in (0.0, 0.5, 1.0, 3.0) for q5 in (0.01, 0.05, 0.1, 0.4)
            for y in (0.0, -1.0, -3.0))
report("largest difference, exact onset time minus bisection (48 waves)",
       f"{worst:.1e}")
check(worst < 1e-12 and abs(onset_time(0.0, 0.05, 0.0) - np.log(1 / 0.05)) < 1e-14,
      "the exact onset time agrees with bisection; q1 = 0, y = 0: ln(m / q5)")
onset = onset_time(0.5, 0.05, 0.0)  # the wave followed below
report("onset time of the wave q1 = 0.5, q5 = 0.05, y = 0", f"{onset:.6f}")
```

For $4 \times 4 \times 3 = 48$ waves the formula and the bisection agree to `8.9e-16`; the check also confirms the short form $\ln(m/q_5) = \ln 20$ for $q_1 = 0$, $y = 0$. The onset time of the wave followed below is printed as `2.996044`.

In [7], the recorded sample as an instant of the history.

```
instant = np.log(40.0)  # the time at which k5 = 0.05 e^x4 = 2
k5_instant = frame_momenta(instant, 0.0, 0.05, 0.0)[1]
eigenvalues = np.linalg.eigvals(mode_hamiltonian(instant, 0.0, 0.05, 0.0))
plus = int(np.sum(np.abs(eigenvalues - 1j * np.sqrt(3)) < 1e-9))
minus = int(np.sum(np.abs(eigenvalues + 1j * np.sqrt(3)) < 1e-9))
early = np.linalg.eigvals(mode_hamiltonian(0.0, 0.0, 0.05, 0.0))
```

At $x_4 = \ln 40$ the wave $q_1 = 0$, $q_5 = 0.05$, $y = 0$ has $k_5 = 0.05 \cdot 40 = 2$. The 16 eigenvalues of that instant are counted near $+i\sqrt{3}$ and near $-i\sqrt{3}$; `early` are the eigenvalues of the same wave at $x_4 = 0$, where $k_5 = 0.05$.

```
report("frame momentum k5 at x4 = ln 40", f"{k5_instant:.12f}")
report("eigenvalues +i sqrt(3) and -i sqrt(3), how many", f"{plus} and {minus}")
largest_imaginary = np.max(np.abs(early.imag))  # 0 up to rounding: oscillation
report("largest imaginary part of an eigenvalue at x4 = 0", f"{largest_imaginary:.1e}")
check_record(abs(k5_instant - 2) < 1e-12 and (plus, minus) == (8, 8)
             and largest_imaginary < 1e-12,
             "the recorded sample m = 1, k5 = 2 (+-i sqrt 3) is reached at x4 = ln 40",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "extra_time_modes_grow")
```

The printed lines show $k_5 = 2.000000000000$, eight eigenvalues near each of $\pm i\sqrt{3}$, and at $x_4 = 0$ a largest imaginary part of `1.8e-16` (zero up to rounding: the wave still oscillates). The check reproduces the record check `extra_time_modes_grow` and places its sample on the deflating history.

In [8], the eigenvalues of one wave through the onset.

```
scan_times = np.linspace(0.0, 5.0, 251)
real_parts, imaginary_parts, worst = [], [], 0.0
for x4 in scan_times:
    eigenvalues = np.linalg.eigvals(mode_hamiltonian(x4, 0.5, 0.05, 0.0))
    real_parts.append(np.sort(eigenvalues.real))
    imaginary_parts.append(np.sort(eigenvalues.imag))
    w2 = w_squared(x4, 0.5, 0.05, 0.0)
    if abs(w2) > 0.05:  # away from the onset
        w = np.sqrt(complex(w2))  # real, or i kappa after the onset
        predicted = np.array([w] * 8 + [-w] * 8)
        worst = max(worst,
                    np.max(np.abs(np.sort(eigenvalues.real) - np.sort(predicted.real))),
                    np.max(np.abs(np.sort(eigenvalues.imag) - np.sort(predicted.imag))))
report("largest difference from +-w(x4) away from the onset", f"{worst:.1e}")
check(worst < 1e-10, "at every instant the eigenvalues of h(x4) are +-w(x4), 8 each")
```

The loop of In [9] of Notebook 10a (Section 10.10), now along the history: for the wave $q_1 = 0.5$, $q_5 = 0.05$ at 251 times from 0 to 5 it computes the 16 eigenvalues of $h(x_4)$, stores their sorted real and imaginary parts, and, away from the onset (where the matrix cannot be diagonalised), compares them with $\pm w(x_4)$, eight each. The largest difference is printed as `8.0e-15`.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.0), sharex=True)
axes[0].plot(scan_times, np.array(real_parts), color=BLUE, linewidth=2)
axes[1].plot(scan_times, np.array(imaginary_parts), color=ORANGE, linewidth=2)
for ax, what in ((axes[0], "real part"), (axes[1], "imaginary part")):
    ax.axvline(onset, color=GREY, linestyle=":", linewidth=1)
    ax.set_xlabel("time $x_4$ (units of $1/m$)")
    ax.set_ylabel(f"{what} of the eigenvalues (units of $m$)")
axes[0].set_title("oscillation before the onset")
axes[1].set_title("growth after the onset")
save_figure(fig, "eigenvalues_along_history",
...)
```

The real parts (left) and imaginary parts (right) against the time, with a dotted line at the onset. Figure 2 of Notebook 10f shows the real frequencies $\pm w(x_4)$ closing in to 0 at $x_4^* = 2.996$ and the imaginary parts opening up after it, growing further as the extra-time frame momentum keeps growing: the picture of Figure 3 of Notebook 10a, now produced by the deflation itself.

In [9], the Krein inertia of one wave along the history.

```
def orthonormal_basis(P):
    basis = []
    for column in P.T:
        v = column.astype(complex)
        for _ in range(2):  # the second pass removes rounding errors
            for e in basis:
                v = v - (e.conj() @ v) * e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:
            basis.append(v / length)
    return np.array(basis).T
```

The Gram-Schmidt function of In [10] of Notebook 10a (Section 10.10).

```
def eigenspace(h, w2, sign):
    w = np.sqrt(complex(w2))
    return orthonormal_basis((np.eye(16) + sign * h / w) / 2)

def krein_inertia(V):
    values = np.linalg.eigvalsh(V.conj().T @ B @ V)
    return (int(np.sum(values > 1e-8)), int(np.sum(values < -1e-8)),
            int(np.sum(np.abs(values) <= 1e-8)))
```

`eigenspace(h, w2, sign)` returns an orthonormal basis of the eigenspace of $\pm w$ (or $\pm i\kappa$) of a given matrix h, as the range of the projector $\frac{1}{2}(I_{16} \pm h/w)$; `krein_inertia(V)` counts the positive, negative and zero eigenvalues of the Gram matrix $V^\dagger B V$ (Section 10.5), as in Notebook 10a.

```
kept = [x4 for x4 in scan_times if abs(x4 - onset) > 0.03]
inertias = [krein_inertia(eigenspace(mode_hamiltonian(x4, 0.5, 0.05, 0.0),
                                     w_squared(x4, 0.5, 0.05, 0.0), +1))
```

```
            for x4 in kept]
before = {c for x4, c in zip(kept, inertias) if x4 < onset}
after = {c for x4, c in zip(kept, inertias) if x4 > onset}
say(f"inertia before the onset: {sorted(before)}; after the onset: {sorted(after)}")
```

The inertia of the $+w$ eigenspace at every time farther than 0.03 from the onset. `before` and `after` are the **sets** of the different inertias found before and after the onset (a set, written with braces, keeps each value once). The printed line shows `[(4, 4, 0)]` before and `[(0, 0, 8)]` after.

```
check_record(before == {(4, 4, 0)},
             "every instant before the onset: inertia (4, 4) (real frequency)",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_Krein_inertia_proof")
check_record(after == {(0, 0, 8)},
             "every instant after the onset: the eigenspace is Krein-neutral",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_complex_frequency_Krein_neutral")
```

Two PASS lines, reproducing the record checks of Theorem 10.1 instant by instant.

```
counts = np.array(inertias)
fig, ax = plt.subplots()
width = 0.0205  # a little wider than the step 0.02 between the times (no gaps)
ax.bar(kept, counts[:, 0], width=width, color=BLUE,
       label="positive charge $u^\\dagger B u > 0$")
ax.bar(kept, counts[:, 1], width=width, bottom=counts[:, 0], color=ORANGE,
       label="negative charge $u^\\dagger B u < 0$")
ax.bar(kept, counts[:, 2], width=width, bottom=counts[:, 0] + counts[:, 1],
       color=GREEN, label="neutral")
```

Stacked bars, as in In [14] of Notebook 10a: at each time a bar of height 8, split into its positive (blue), negative (orange) and neutral (green) directions.

```
ax.axvline(onset, color=GREY, linestyle=":", linewidth=1)
ax.set_xlabel("time $x_4$ (units of $1/m$)")
ax.set_ylabel("directions in the $+w$ eigenspace")
ax.set_yticks(range(0, 9))
ax.set_ylim(0.0, 10.5)  # room for the legend above the bars
ax.set_title("Krein inertia of one wave along the deflating history")
ax.legend(loc="upper center", ncol=3, fontsize=8)
save_figure(fig, "inertia_along_history",
...)
```

Figure 3 of Notebook 10f shows half-blue, half-orange bars up to the onset time 2.996 and green bars after it: the deflation of the extra times moves the wave from the kind with inertia $(4, 4)$ to the Krein-neutral kind at a definite time.

In [10], the onset map.

```
map_times = np.linspace(0.0, 6.0, 241)
exponents = np.linspace(-3.0, 0.0, 121)  # log10 of q5
q5_values = 10.0 ** exponents
real_frequency = np.array([[w_squared(x4, 0.5, q5, 0.0) > 0 for x4 in map_times]
                           for q5 in q5_values])  # rows: q5, columns: x4
onsets = np.array([onset_time(0.5, q5, 0.0) for q5 in q5_values])
agree = np.array_equal(real_frequency, map_times[None, :] < onsets[:, None])
```

A grid of 241 times from 0 to 6 and 121 momenta q_5 from 10^{-3} to 1, equally spaced in $\log_{10} q_5$ (`10.0 ** exponents`). `real_frequency` is a table of truth values, true where $w^2 > 0$. `onsets` holds the exact onset of each momentum, and `agree` compares the table with "the time lies before the onset": `map_times[None, :]` is a row and `onsets[:, None]` a column, and comparing them gives the whole table at once.

```
sampled, sample_ok = 0, True
for i in range(0, 121, 4):
    for j in range(0, 241, 60):
        x4, q5 = map_times[j], q5_values[i]
        if abs(x4 - onsets[i]) < 0.05:
            continue  # too close to the onset
        w2 = w_squared(x4, 0.5, q5, 0.0)
        found = krein_inertia(eigenspace(mode_hamiltonian(x4, 0.5, q5, 0.0), w2, +1))
        sample_ok = sample_ok and found == ((4, 4, 0) if w2 > 0 else (0, 0, 8))
        sampled += 1
```

At every fourth momentum and every 60th time (`range(0, 121, 4)` counts in steps of 4) the Krein inertia is computed directly and compared with the prediction: $(4, 4, 0)$ for a real frequency, $(0, 0, 8)$ for an imaginary one; points closer than 0.05 to the onset are skipped (`continue` jumps to the next pass of the loop).

```
report("grid points sampled for the inertia", sampled)
report("onset time for q5 = 0.001 and for q5 = 1",
       f"{onsets[0]:.4f} and {onsets[-1]:.4f}")
check(agree and sample_ok and np.all(np.isfinite(onsets)),
      "the map agrees with the exact onset; (4, 4) before it, neutral after it")
```

153 grid points are sampled; the onset times run from `6.9078` ($q_5 = 0.001$) to `0.0941` ($q_5 = 1$). The check requires the agreement, the sampled inertias, and a finite onset for every momentum (`np.isfinite`): no wave with extra-time momentum keeps a real frequency for ever.

```
from matplotlib.colors import ListedColormap  # a colour scale with two colours

fig, ax = plt.subplots(figsize=(7.0, 4.8))
ax.pcolormesh(map_times, exponents, real_frequency.astype(float),
              cmap=ListedColormap(["#f6c9b5", "#bcd6f5"]), vmin=0, vmax=1,
              shading="nearest")
inside = onsets <= map_times[-1]  # the part of the onset curve inside the map
ax.plot(onsets[inside], exponents[inside], color=GREY, linewidth=2,
        label="onset time $x_4^\\ast$")
ax.set_xlim(map_times[0], map_times[-1])
```

`ax.pcolormesh` colours every grid cell by the table (`astype(float)` turns the truth values into 0 and 1): light orange for 0 (imaginary frequency) and light blue for 1 (real frequency); `shading="nearest"` centres each cell on its grid point. The grey curve is the exact onset time, drawn where it lies inside the map.

```
for a4_slice in slices:
    ax.axvline(a4_slice / (A * H), color=GREEN, linestyle="--", linewidth=1)
ax.plot([], [], "--", color=GREEN, label="slices $a_{4,0}$ of the Kohn-Sham record")
ax.text(0.3, -1.9, "real frequency:\ninertia (4, 4)", color=BLUE, fontsize=9)
ax.text(4.4, -0.6, "imaginary frequency:\nKrein-neutral", color=ORANGE, fontsize=9)
ax.set_xlabel("time $x_4$ (units of $1/m$)")
ax.set_ylabel("$\\log_{10}$ of the extra-time momentum $q_5$")
ax.set_title("Which waves still oscillate? ($q_1 = 0.5$, $y = 0$)")
ax.legend(loc="lower left", fontsize=8)  # the lower left corner is all blue
ax.grid(False)
save_figure(fig, "onset_map",
...)
```

Green dashed lines mark the times $x_4 = a_{4,0}/(AH)$ of the five slices of the Kohn-Sham record; the two texts (with a line break written as a backslash and n) name the two regions. Figure 4 of Notebook 10f shows the blue region shrinking towards small q_5 as time goes on, bounded by the grey onset curve, which is nearly a straight line on this logarithmic scale (for small q_5, $x_4^* \approx \ln(1/q_5)$): the band of oscillating extra-time waves shrinks exponentially, and only the good sector $q_5 = 0$ stays blue for ever.

In [11], the good sector along the history.

```
slice_ok, table = True, []
for q1 in (0.5, 1.0, 2.0, 4.0):
    for a4_slice in slices:
        x4 = a4_slice / (A * H)  # the time of the slice
        h = mode_hamiltonian(x4, q1, 0.0, 0.0)
        E = np.sqrt(w_squared(x4, q1, 0.0, 0.0))
        U_plus = eigenspace(h, E ** 2, +1)  # the 8 particle columns u_s
        V_minus = eigenspace(h, E ** 2, -1)  # the 8 antiparticle columns v_s
```

For four momenta $q_1 = 0.5, 1, 2, 4$ ($q_5 = 0$, $y = 0$) and the five slices, the cell builds the instantaneous good-sector waves: the energy $E(x_4) = \sqrt{w^2}$ and orthonormal bases of the eigenspaces of $+E$ (the particle columns) and $-E$ (the antiparticle columns).

```
        sea = sum((v.conj() @ h @ v).real for v in V_minus.T)
        particle = [(u.conj() @ h @ u).real for u in U_plus.T]
        antiparticle = [-(v.conj() @ h @ v).real for v in V_minus.T]
```

The value of the filled sea, $\sum_s v_s^\dagger h v_s$ (each term is $-E$), and the normal-ordered energies of a particle, $u_s^\dagger h u_s$, and of an antiparticle, $-v_s^\dagger h v_s$ (Section 10.20).

```
        slice_ok = (slice_ok and np.allclose(h, h.conj().T) and np.allclose(B @ h, h @ B)
                    and U_plus.shape[1] == 8 and V_minus.shape[1] == 8
```

```
                    and krein_inertia(U_plus) == (4, 4, 0)
                    and krein_inertia(V_minus) == (4, 4, 0)
                    and abs(sea + 8 * E) < 1e-12
                    and np.allclose(particle, E) and np.allclose(antiparticle, E))
        table.append((q1, a4_slice, E, sea))
```

At each slice: h Hermitian, $Bh = hB$, eight columns in each eigenspace, Krein inertia $(4, 4)$ on both, the sea value $-8E$, and every quantum $+E$. A row of the table is kept for the printout and the figure.

```
say("q1    a4,0    E(x4)      sea value -8E")
for q1, a4_slice, E, sea in table:
    if q1 in (1.0, 4.0):  # print two of the four momenta
        say(f"{q1:3.1f}   {a4_slice:3.1f}   {E:9.6f}   {sea:11.6f}")
check_record(slice_ok,
             "good sector at all 5 slices: Hermitian, [B, h] = 0, +-E, (4, 4), sea -8E",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_spectrum_and_B_sectors")
```

The printed table shows, for $q_1 = 1$, the energies 1.414214, 1.169564, 1.065521, 1.024591, 1.009116 at $a_{4,0} = 0, 0.5, 1, 1.5, 2$ (that is $\sqrt{1 + e^{-2a_{4,0}}}$), with the sea values -8 times these, from -11.313708 to -8.072930; and for $q_1 = 4$ the energies from 4.123106 down to 1.137124. The check reproduces the record check `good_sector_spectrum_and_B_sectors` at every slice.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
for q1, colour in ((0.5, BLUE), (1.0, ORANGE), (2.0, GREEN), (4.0, GREY)):
    E_curve = np.sqrt(w_squared(curve_times, q1, 0.0, 0.0))
    axes[0].plot(curve_times, E_curve, color=colour, linewidth=2, label=f"$q_1 = {q1}$")
    axes[1].plot(curve_times, -8 * E_curve, color=colour, linewidth=2,
                 label=f"$q_1 = {q1}$")
    dots = [(a4_slice, E, sea) for q, a4_slice, E, sea in table if q == q1]
    axes[0].plot([d[0] for d in dots], [d[1] for d in dots], "o", color=colour)
    axes[1].plot([d[0] for d in dots], [d[2] for d in dots], "o", color=colour)
```

For each momentum the curves $E(x_4)$ (left) and $-8E(x_4)$ (right) are drawn from the formula, and the values computed from the eigenvectors at the slices as dots (the time of a slice equals $a_{4,0}$, because $AH = 1$).

```
axes[0].axhline(mass, color=GREY, linestyle=":", linewidth=1)
axes[1].axhline(-8 * mass, color=GREY, linestyle=":", linewidth=1)
axes[0].set_ylabel("energy $E(x_4)$ of one quantum (units of $m$)")
axes[1].set_ylabel("value $-8E(x_4)$ of the filled sea (units of $m$)")
axes[0].set_title("particles and antiparticles: $+E(x_4) > 0$")
axes[1].set_title("the instantaneous vacuum")
for ax in axes:
    ax.set_xlabel("time $x_4$ (units of $1/m$)")
    ax.legend(fontsize=8)
save_figure(fig, "good_sector_energies",
...)
```

Dotted lines at the limits m and $-8m$. Figure 5 of Notebook 10f shows the four energy curves falling towards the mass as 3-space inflates (larger q_1 fall from higher), with the dots on them, and the sea values rising towards $-8m$: in the good sector every quantum has a positive energy at every time, and the inertia stays $(4, 4)$.

In [12], the universes of masses $+m$ and $-m$ along the history.

```
pair_ok, worst = True, 0.0
for x4 in np.linspace(0.0, 6.0, 25):
    h_plus = mode_hamiltonian(x4, 0.5, 0.05, 0.0, m=mass)
    h_minus = mode_hamiltonian(x4, 0.5, 0.05, 0.0, m=-mass)
    pair_ok = pair_ok and np.allclose(Gamma @ h_plus @ Gamma, h_minus, atol=1e-14)
    values_plus = np.linalg.eigvals(h_plus)
    values_minus = np.linalg.eigvals(h_minus)
```

At 25 times from 0 to 6, for the wave $q_1 = 0.5$, $q_5 = 0.05$, the cell builds $h_m(x_4)$ and $h_{-m}(x_4)$ (the default mass is overridden with `m=-mass`), checks $\Gamma h_m \Gamma = h_{-m}$ to within 10^{-14} (`atol` is the allowed absolute difference), and computes both spectra.

```
    # compare the sorted real parts and the sorted imaginary parts separately
    worst = max(worst,
                np.max(np.abs(np.sort(values_plus.real) - np.sort(values_minus.real))),
                np.max(np.abs(np.sort(values_plus.imag) - np.sort(values_minus.imag))))
report("largest difference of the eigenvalues for +m and -m", f"{worst:.1e}")
check_record(pair_ok and worst < 1e-9,
             "Gamma h_m(x4) Gamma = h_-m(x4) at every time: same spectra and onset",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.one_particle_maps")
```

The sorted real parts and imaginary parts are compared separately, as the comment says (the times include the onset region, where the eigenvalues are complex). The largest difference is printed as `7.1e-15`, and the check reproduces the record check `Q.one_particle_maps` along the whole history.

In [13], the last check.

```
for name in ("10f_1_hermiticity_defect.png", "10f_2_eigenvalues_along_history.png",
             "10f_3_inertia_along_history.png", "10f_4_onset_map.png",
             "10f_5_good_sector_energies.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The five figure files exist, and the last line prints ALL 19 CHECKS PASSED (notebook 10f): the five figure checks and the 14 checks of the cells before (1 each in In [2], In [3], In [5] to In [8], In [10], In [11] and In [12], 3 in In [4] and 2 in In [9]).

10.44 The quantum reading of the pairing

The pairing theorem T1 of the Revision record (proved in Chapter 18) says that the chirality matrix maps every solution Ψ of the field with mass m and coupling λ to a solution $\Gamma\Psi$ of the field with

$-m$ and $-\lambda$, with the energy-momentum tensor and the current reversed: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$, $T \to -T$, $J \to -J$. Theorem T2 combines Γ with a reflection; in the author's field it is the mirror $\gamma^{(x_0)}$ across the ASSUMED Z2 brane, and it pairs (m, λ) with $(-m, \lambda)$ at equal energy. What do these maps mean once dirac16complex is QUANTISED? The Revision pairing record answers with five statements, the **quantum reading Q** (record `Revision/pairing/pairing-theory.json`, theorem entry `Q`; Revision proof document, section 6). This section derives them, in flat 4+4 space at one point with $U = 0$ (so $\lambda = 0$; the record states them for general λ).

The hypotheses. (HQ1) dirac16complex is canonically quantised with x_4 as the evolution time; the x_4-derivative kernel of its Lagrangian is $N = B$ and the canonical anticommutator is $\{\Psi, \Psi^\dagger\} = N^{-1} = B$ at one point (Section 10.12). (HQ2) dirac16complex00 is a classical field and has no quantum reading.

Two sign rules. Γ anticommutes with every gamma, so moving it through a product of n gammas costs $(-1)^n$; with $\Gamma\Gamma = I_{16}$:

$$\Gamma C \Gamma = C \ (n = 4), \qquad \Gamma C \gamma^{(x_a)} \Gamma = -C\gamma^{(x_a)} \ (n = 5), \qquad \Gamma B \Gamma = -B \ (n = 5).$$

The Lagrangian identity, line by line. In flat space with $U = 0$, $\mathcal{L}_m[\Psi] = \frac{1}{2}\sum_a (\Psi^\dagger C\gamma^{(x_a)}\partial_a\Psi - \partial_a\Psi^\dagger C\gamma^{(x_a)}\Psi) - m\Psi^\dagger C\Psi$. Insert $\Psi = \Gamma\chi$ and $\Psi^\dagger = \chi^\dagger\Gamma$ (Γ is real and symmetric):

$$\mathcal{L}_m[\Gamma\chi] = \tfrac{1}{2}\sum_a \left(\chi^\dagger\Gamma C\gamma^{(x_a)}\Gamma\,\partial_a\chi - \partial_a\chi^\dagger\,\Gamma C\gamma^{(x_a)}\Gamma\chi\right) - m\,\chi^\dagger\Gamma C\Gamma\chi.$$

The two sign rules turn this into

$$\mathcal{L}_m[\Gamma\chi] = -\tfrac{1}{2}\sum_a \left(\chi^\dagger C\gamma^{(x_a)}\partial_a\chi - \partial_a\chi^\dagger C\gamma^{(x_a)}\chi\right) - m\,\chi^\dagger C\chi.$$

Take the sign -1 out of both terms; the mass term becomes $+m\chi^\dagger C\chi = -(-m)\chi^\dagger C\chi$, so the bracket is the Lagrangian with the mass $-m$:

$$\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi].$$

(Q1) The chirality image carries the Krein metric $-B$. By Section 10.15, $\{\Gamma\Psi, (\Gamma\Psi)^\dagger\} = \Gamma B\Gamma^\dagger = -B$. The image's own Lagrangian says the same: in $\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi]$ the time-derivative terms of the variable χ have the kernel $\Gamma B\Gamma = -B$, and canonical quantisation of χ gives $\{\chi, \chi^\dagger\} = (-B)^{-1} = -B$. The two agree.

(Q2) The image is the same quantum system. For one plane wave the energy is $H_m[\Psi] = \Psi^\dagger h'_m\Psi$ with $h'_m = mC - i\sum_a k_a C\gamma^{(x_a)}$ (Section 10.12), and the charge is $Q[\Psi] = \Psi^\dagger B\Psi$. By the sign rules,

$$\Gamma h'_m\Gamma = mC + i\sum_a k_a C\gamma^{(x_a)} = -\Big((-m)C - i\sum_a k_a C\gamma^{(x_a)}\Big) = -h'_{-m}.$$

Written in the image variable $\chi = \Gamma\Psi$ (so $\Psi = \Gamma\chi$),

$$H_m[\Psi] = \chi^\dagger \Gamma h'_m \Gamma \chi = -\chi^\dagger h'_{-m} \chi = -H_{-m}[\Gamma\Psi], \qquad Q[\Psi] = \chi^\dagger \Gamma B \Gamma \chi = -Q[\Gamma\Psi].$$

The energy and the charge of the field are MINUS the energy and the charge that the mass $-m$ theory assigns to the image: $T \to -T$ and $J \to -J$ of T1 are identities between operators of ONE quantum system. The image is not a second universe with negative energy; it is the first universe written in other variables. Its motion agrees. In its own variable $\chi = \Gamma\Psi$ the image has the metric $-B$ (Q1) and, by the display above ($H_m[\Psi] = -\chi^\dagger h'_{-m}\chi$), the generator density $-h'_{-m}$; its one-particle generator is the product of the two, as in Section 10.12, so it evolves by

$$(-B)(-h'_{-m}) = B h'_{-m} = h_{-m},$$

the wave equation of mass $-m$. Written back in the variable $\Psi = \Gamma\chi$, the same motion is $\Gamma h_{-m}\Gamma = (\Gamma B\Gamma)(\Gamma h'_{-m}\Gamma) = (-B)(-h'_m) = B h'_m = h_m$ (insert $\Gamma\Gamma = I_{16}$ between the factors; $\Gamma h'_{-m}\Gamma = -h'_m$ is the identity $\Gamma h'_m \Gamma = -h'_{-m}$ with m replaced by $-m$): the dynamics of Ψ itself. The Revision record states the same identity in the other direction, for the image of a field of mass $-m$: that image carries the metric $-B$ and the generator density $-h'_m$ and evolves by $(-B)(-h'_m) = B h'_m = h_m$, the dynamics of mass m (`python-pairing.json`, check `Q.image_generators_same_dynamics`). In terms of the image field, $i\,\partial_4(\Gamma\Psi) = \Gamma h_m \Psi = (\Gamma h_m \Gamma)(\Gamma\Psi) = h_{-m}\Gamma\Psi$: the image obeys the wave equation of mass $-m$ and is moved by the SAME energy operator $H_m[\Psi]$.

(Q3) An independent universe of mass $-m$, and no cancellation. An independently quantised universe of mass $-m$ is a NEW field Ψ_2 with its own Lagrangian $\mathcal{L}_{-m}[\Psi_2]$. The mass does not enter the time-derivative kernel, so its kernel is $+B$ and $\{\Psi_2, \Psi_2^\dagger\} = +B$; being independent of the first universe Ψ_1, it anticommutes with it: $\{\Psi_{2A}, \Psi_{1C}^\dagger\} = 0$ and $\{\Psi_{2A}, \Psi_{1C}\} = 0$. The image $\Gamma\Psi_1$ fails both requirements: it carries $-B$, not $+B$, and $\{(\Gamma\Psi_1)_A, \Psi_{1C}^\dagger\} = \sum_D \Gamma_{AD} B_{DC} = (\Gamma B)_{AC}$, a matrix of rank 16 (it is invertible), not 0. So no identification $\Psi_2 = \Gamma\Psi_1$ exists. The same holds for the other images built from Ψ_1: the mirror image $\gamma^{(x_0)}\Psi_1$ has the right rule $+B$ but $\{\gamma^{(x_0)}\Psi_1, \Psi_1^\dagger\} = \gamma^{(x_0)} B \neq 0$, and the conjugate field $\Psi^c = \Gamma\Psi_1^{\dagger T}$ has $+B$ (Section 10.15) but $\{\Psi^c_A, \Psi_{1C}\} = \sum_D \Gamma_{AD} B_{CD} = (\Gamma B^T)_{AC} = -(\Gamma B)_{AC} \neq 0$. A second universe must live on a larger state space. There the total energy is $H_1 + H_2$, the generators ADD ($P_{\text{total}} = P_1 \otimes 1 + 1 \otimes P_2$ on the product space), and the T1 identity relates operators of universe 1 only; it gives no relation $P_2 = -P_1$. The one-particle generator of the two universes is the block matrix $\mathrm{diag}(B h'_m, B h'_{-m})$. At zero momentum $B h'_{\pm m} = \pm m BC$, and

$$BC = -iC\gamma^{(x_4)}C = -iCC\gamma^{(x_4)} = -i\gamma^{(x_4)}, \qquad (BC)^2 = -\gamma^{(x_4)}\gamma^{(x_4)} = I_{16}, \qquad \mathrm{tr}(BC) = 0,$$

by (B1) of Section 10.2 and $CC = I_{16}$; so BC has the eigenvalues $+1$ and -1, eight each, and the block generator has the eigenvalues $+m$ and $-m$, sixteen each: none is 0 for $m \neq 0$. With a momentum they are $\pm\sqrt{m^2 + k^2}$, sixteen each. After normal ordering each universe has quanta of energy $+E > 0$ (Section 10.20), so every state of the two universes has a total energy of at least 0, and only the vacuum has 0. A particle in universe 1 (charge $+1$) and an antiparticle in universe 2 (charge -1) have the total charge 0 and the total energy $2E$, NOT 0.

(Q4) Identical one-particle spectra. $\Gamma h_m \Gamma = h_{-m}$ and $\gamma^{(x_0)} h_m(k) \gamma^{(x_0)} = h_{-m}(R_0 k)$, so the one-particle spectra of the universes of masses $+m$ and $-m$ are identical, not opposite (Section 10.6), and along the deflating history at every instant (Section 10.39).

(Q5) The mirror image keeps $+B$. $\gamma^{(x_0)}B(\gamma^{(x_0)})^\dagger = +B$ (Section 10.15): the mirror universe of T2, with $(-m, \lambda)$, can be quantised as an ordinary independent copy with equal energies.

statement	status	where it is verified
(HQ1) kernel $N = B$, $\{\Psi, \Psi^\dagger\} = B\delta^7/\sqrt{\lvert g\rvert}$	PROVED	`wolfram-pairing.json`, checks `Q_symplectic_kernel_grassmann` and `Q_symplectic_kernel_commuting`; `python-pairing.json`, check `Q.canonical_anticommutator`
(Q1) the image carries $-B$, also from its own Lagrangian	PROVED	`wolfram-pairing.json`, check `Q_Krein_metric_of_images`; `python-pairing.json`, checks `Q.image_krein_metric` and `Q.image_own_quantisation`
(Q2) the image's generators are those of Ψ; $T \to -T$, $J \to -J$ inside one system	PROVED	`wolfram-pairing.json`, checks `Q_generators_of_the_image_grassmann` and `Q_generators_of_the_image_commuting`; `python-pairing.json`, check `Q.image_generators_same_dynamics`
(Q3) no identification with an independent universe; generators add; block eigenvalues $\pm m$, 16 each	PROVED	`wolfram-pairing.json`, check `Q_no_identification_of_independent_universes`; `python-pairing.json`, check `Q.no_cancellation_independent_universes`
(Q4) identical one-particle spectra; inertia $(4, 4)$ at real frequencies	PROVED	Sections 10.5 and 10.6; `wolfram-pairing.json`, checks `Q_one_particle_maps` and `Q_one_particle_Krein_inertia_real_frequencies`; `python-pairing.json`, checks `Q.one_particle_maps` and `Q.one_particle_Krein_inertia_proof`
(Q5) the mirror image keeps $+B$	PROVED	`python-pairing.json`, check `Q.T2_image_keeps_B`
the two engines agree on Q	PROVED	`python-pairing.json`, check `compare.theory.theorem_Q` (10 sympy checks confirm the 12 Wolfram verifications)

The statements Q1 to Q5 are statements about the canonical anticommutator; they neither use nor establish a positive state space for either universe (the positive Fock spaces of this chapter are built for single good-sector momenta with frozen coefficients).

10.45 What the quantum reading does not establish

The author asked to prove that universes of masses $+m$ and $-m$ are created in pairs. The honest answer, as far as this chapter reaches, is the following.

What is proved. The quantum reading Q1 to Q5 of Section 10.44, under the hypotheses HQ1 and HQ2, and the identical one-particle spectra of the universes of masses $+m$ and $-m$ (Sections 10.6 and 10.39). Like the classical theorems T1 and T2 (Chapter 18) they are exact MAPS BETWEEN SOLUTIONS and statements about operators; they say what the quantum theory does with a solution, its image and a second universe.

What is NOT established (the Revision record lists the same points, written independently by the two verification engines: `python-pairing.json`, check `compare.theory.not_established`):

1. No creation process. Nothing in these equations produces a universe, a pair of universes or a change of the number of universes; no transition from "no universe" to "two universes", no initial state, no vacuum decay (the transition of a state of lowest energy into another state of still lower energy) and no tunnelling process (a quantum transition through a barrier that the classical motion cannot cross) is derived.

2. No rate, probability or amplitude. No transition amplitude, probability, rate or Bogoliubov coefficient for creating universes of masses $+m$ and $-m$ is computed or implied (when the background changes in time, a **Bogoliubov coefficient** measures how much of a wave of negative frequency at a later time is contained in a wave of positive frequency at an earlier time; its square counts the quanta that the change creates). No wave function of the universe (in quantum cosmology, a quantum state of the geometry of the whole universe, from which probabilities for universes are computed) is part of these statements.

3. No dynamical necessity. No equation and no conservation law forces the partner to exist: a single universe of mass $+m$ is an equally valid solution without its partner.

4. No cancellation between two universes. The vanishing of the total energy-momentum and charge of a T1 pair holds for classical bilinears and, as Q2 shows, as an operator identity within ONE quantum system. For two independently quantised universes the generators ADD; a pair of total charge 0 has the positive energy $2E$ (Section 10.44).

5. No positive quantum theory of the whole field. The canonical rule forces a Krein space (Theorem 10.2); in flat 4+4 space every real-frequency eigenspace has Krein inertia $(4, 4)$; a positive Fock space is constructed and checked only for single good-sector momenta with frozen coefficients; the extra-time sector grows and becomes Krein-neutral along the deflating history (Section 10.39); the curved good sector needs a boundary condition at $z = \pi/2$ that the quantisation record does not impose (Section 10.27).

6. The gravitational field is a fixed background, the same for both members; the back-reaction through the field equations for a_4 is not part of these statements, and the history $a_4 = AHx_4$ used in Section 10.39 is a PRESCRIBED BACKGROUND.

7. dirac16complex00 is a classical field; no quantum statement is made for it.

The hypothesis. That the big bang creates universes in pairs of masses $+m$ and $-m$ is the author's HYPOTHESIS. This chapter neither supports nor refutes it: it contains no creation process. Chapter 20 states the hypothesis, what the equations prove, and what they do not, for both fields; Chapter 21 treats matter and antimatter, where the conjugation of the quantised field $\Psi \to \Gamma\Psi^{\dagger T}$ of Section 10.15 (which reverses the mass) appears again, and states precisely that the theory as built does not solve the matter-antimatter problem.

10.46 Example: Notebook 10g checks the quantum reading of the pairing

Notebook 10g proves the Lagrangian identity $\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi]$ for symbolic field components and computes the three time-derivative kernels B, $-B$ and $+B$ (Q1, Q3); checks on a Fock space that the image carries $-B$ and the mirror image $+B$ (Q1, Q5); checks $H_m[\Psi] = -H_{-m}[\Gamma\Psi]$ and $Q[\Psi] = -Q[\Gamma\Psi]$ as operator identities on 150 random states and that the image obeys the wave equation of mass $-m$ under the same energy operator (Q2); tests three candidates for an independent universe (Q3); builds two independently quantised universes on 32 fermion modes, computes their block generator, and counts all 2^{32} states of one good-sector momentum in both universes (Q3). It draws five figures and ends with the line ALL 30 CHECKS PASSED (notebook 10g).

10.47 How to run Notebook 10g

Step 1. What this notebook does and what it needs.

Notebook 10g (The quantum reading of the pairing: one system or two universes) is the file `Revision /textbook/notebooks/10g_quantum_pair_reading.ipynb` of the repository Dirac_claude. It checks, exactly with sympy and on explicit fermionic Fock spaces, the quantum reading Q of the Revision pairing record: the Lagrangian identity L_m of Gamma chi equals minus L_-m of chi, the time-derivative kernels of the three Lagrangians involved (the field, its chirality image, an independent universe of mass -m), the canonical anticommutators they force (+B, -B, +B), that the chirality image Gamma Psi carries the Krein metric -B and the mirror image keeps +B, that the energy and the charge of the field are minus those that the mass -m theory assigns to its image (one quantum system, T to -T and J to -J as operator identities), that two independently quantised universes of masses +m and -m have the anticommutator +B each, anticommute with each other and cannot be identified with the image, and that their generators add without cancelling (block eigenvalues +m and -m, 16 each; one good-sector momentum: every state of the product Fock space has a non-negative total energy, a pair of zero total charge has energy 2E); five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs

the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is

changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10g_quantum_pair_reading.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10g_quantum_pair_reading.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 10g_quantum_pair_reading.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/10g.captions.json`

- `Revision/textbook/figures/10g_1_krein_metrics.png`
- `Revision/textbook/figures/10g_2_one_system.png`
- `Revision/textbook/figures/10g_3_anticommutator_blocks.png`
- `Revision/textbook/figures/10g_4_block_generator.png`
- `Revision/textbook/figures/10g_5_two_universe_states.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10g_5_two_universe_states.png exists
ALL 30 CHECKS PASSED (notebook 10g)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 10g_quantum_pair_reading.ipynb
python -m nbconvert --execute --inplace 10g_quantum_pair_reading.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

10.48 Notebook 10g: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The pairing theorem T1 of the Revision record says that the chirality matrix
$\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ turns every solution
$\Psi$ of the field of mass $m$ (and coupling $\lambda$) into a solution
$\Gamma\Psi$ of the field of mass $-m$ (and coupling $-\lambda$), with the
```

```
energy-momentum tensor and the current reversed: $T \to -T$, $J \to -J$. What
does this mean once dirac16complex is QUANTISED? The Revision pairing record
answers with five statements, the *quantum reading* Q. This notebook checks the
four of them that concern the canonical anticommutator, exactly with sympy and on
explicit fermionic Fock spaces (the fifth, about one-particle spectra, is the
subject of the first notebook of this chapter). It

- proves the Lagrangian identity $\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi]$
  for symbolic field components, and computes the time-derivative kernels of three
  Lagrangians: that of the field $\Psi$, that of its chirality image $\chi =
  \Gamma\Psi$ (the same system written in new variables) and that of an
  independent universe of mass $-m$; they force the canonical anticommutators
  $+B$, $-B$ and $+B$;
- checks on a Fock space that the image $\Gamma\Psi$ carries the Krein metric $-B$,
  while the mirror image $\gamma^{(x_0)}\Psi$ of theorem T2 keeps $+B$;
- checks that the energy and the charge of the field are MINUS the energy and the
  charge that the mass $-m$ theory assigns to the image: $T \to -T$ and $J \to -J$
  hold as identities between operators of ONE quantum system;
- builds two independently quantised universes of masses $+m$ and $-m$ on one Fock
  space and checks that each has the anticommutator $+B$, that they anticommute
  with each other, and that the image $\Gamma\Psi$ cannot be one of them;
- shows that their energies ADD and never cancel: the block generator has the
  eigenvalues $+m$ and $-m$ (16 each, none zero), and for one good-sector momentum
  every state of the two universes has a total energy of at least 0, while a pair
  of total charge 0 has the energy $2E$, not 0;
- reproduces the corresponding checks of the Revision record and draws five
  teaching figures.

Nothing here describes the CREATION of a universe or of a pair: the statements are
about how the canonical rule treats a solution, its image and a second universe.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 10g (The quantum reading of the pairing: one system or two universes) is the
file ‘Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb‘ of the repository
Dirac_claude. It checks, exactly with sympy and on explicit fermionic Fock spaces, the
quantum reading Q of the Revision pairing record: the Lagrangian identity L_m of Gamma
chi equals minus L_-m of chi, the time-derivative kernels of the three Lagrangians
involved (the field, its chirality image, an independent universe of mass -m), the
canonical anticommutators they force (+B, -B, +B), that the chirality image Gamma Psi
carries the Krein metric -B and the mirror image keeps +B, that the energy and the charge
of the field are minus those that the mass -m theory assigns to its image (one quantum
system, T to -T and J to -J as operator identities), that two independently quantised
universes of masses +m and -m have the anticommutator +B each, anticommute with each
other and cannot be identified with the image, and that their generators add without
cancelling (block eigenvalues +m and -m, 16 each; one good-sector momentum: every state
of the product Fock space has a non-negative total energy, a pair of zero total charge
has energy 2E); five teaching figures. It needs a computer with Windows 11, macOS or
Linux, an internet connection for the installation, the program Git, and Python 3.12 or
```

newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 10g_quantum_pair_reading.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 10g_quantum_pair_reading.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 10g_quantum_pair_reading.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/10g.captions.json‘
- ‘Revision/textbook/figures/10g_1_krein_metrics.png‘
- ‘Revision/textbook/figures/10g_2_one_system.png‘
- ‘Revision/textbook/figures/10g_3_anticommutator_blocks.png‘
- ‘Revision/textbook/figures/10g_4_block_generator.png‘
- ‘Revision/textbook/figures/10g_5_two_universe_states.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 10g_5_two_universe_states.png exists
ALL 30 CHECKS PASSED (notebook 10g)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for

programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 10g_quantum_pair_reading.ipynb
python -m nbconvert --execute --inplace 10g_quantum_pair_reading.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below the folder Revision: the notebook reads files of the Revision record: the data it starts from and the report files whose checks it reproduces (each cited check must still exist there with the verdict PASS). It must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.
- "AssertionError: the cited record check is missing or not PASS": a report file of the Revision record no longer holds the check that the notebook names, or holds it with another verdict: the copy of the repository is incomplete or was changed. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 10g (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 10g (The quantum reading of the pairing: one system or two universes) is the
# file Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb of the repository
# Dirac_claude. It checks, exactly with sympy and on explicit fermionic Fock spaces, the
# quantum reading Q of the Revision pairing record: the Lagrangian identity L_m of Gamma
# chi equals minus L_-m of chi, the time-derivative kernels of the three Lagrangians
# involved (the field, its chirality image, an independent universe of mass -m), the
# canonical anticommutators they force (+B, -B, +B), that the chirality image Gamma Psi
# carries the Krein metric -B and the mirror image keeps +B, that the energy and the
# charge of the field are minus those that the mass -m theory assigns to its image (one
# quantum system, T to -T and J to -J as operator identities), that two independently
# quantised universes of masses +m and -m have the anticommutator +B each, anticommute
# with each other and cannot be identified with the image, and that their generators add
# without cancelling (block eigenvalues +m and -m, 16 each; one good-sector momentum:
# every state of the product Fock space has a non-negative total energy, a pair of zero
```

```
# total charge has energy 2E); five teaching figures. It needs a computer with Windows
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
```

```
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
```

```
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 10g_quantum_pair_reading.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 10g_quantum_pair_reading.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 10g_quantum_pair_reading.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/10g.captions.json
# - Revision/textbook/figures/10g_1_krein_metrics.png
# - Revision/textbook/figures/10g_2_one_system.png
# - Revision/textbook/figures/10g_3_anticommutator_blocks.png
# - Revision/textbook/figures/10g_4_block_generator.png
# - Revision/textbook/figures/10g_5_two_universe_states.png
```

```
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 10g_5_two_universe_states.png exists
#     ALL 30 CHECKS PASSED (notebook 10g)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/10g_quantum_pair_reading.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 10g_quantum_pair_reading.ipynb
#     python -m nbconvert --execute --inplace 10g_quantum_pair_reading.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
```

```
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below the folder Revision: the notebook reads files of
#   the Revision record: the data it starts from and the report files whose checks it
#   reproduces (each cited check must still exist there with the verdict PASS). It must
#   be opened inside the folder Revision/textbook/notebooks of a complete copy of the
#   repository (a notebook copied alone to another folder cannot find them). Clone the
#   repository again and open the notebook there.
# - "AssertionError: the cited record check is missing or not PASS": a report file of the
#   Revision record no longer holds the check that the notebook names, or holds it with
#   another verdict: the copy of the repository is incomplete or was changed. Clone the
#   repository again and open the notebook there.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================

## 3. The words used in this notebook

- **Chirality image**: for a field $\Psi$, the field $\chi = \Gamma\Psi$. Because
  $\Gamma^2 = I_{16}$, also $\Psi = \Gamma\chi$: the image carries exactly the
  same information, written in other variables.
- **Mirror image**: the field $\gamma^{(x_0)}\Psi$ (with the hidden direction
  reflected) of the pairing theorem T2.
- **Lagrangian $\mathcal{L}_m[\Psi]$**: the Lagrangian density of dirac16complex
  with mass $m$, evaluated on the field $\Psi$. Here (flat 4+4 space, $U = 0$) it is
  $\frac12\sum_a(\Psi^\dagger C\gamma^{(x_a)}\partial_a\Psi -
  \partial_a\Psi^\dagger C\gamma^{(x_a)}\Psi) - m\Psi^\dagger C\Psi$.
- **Time-derivative kernel** $N$: the matrix in the terms of a Lagrangian that
  contain $\partial_4$, written as $\frac{i}{2}(\Psi^\dagger N\partial_4\Psi -
  \partial_4\Psi^\dagger N\Psi)$. Canonical quantisation turns it into the
  anticommutator $\{\Psi_A, \Psi^\dagger_C\} = (N^{-1})_{AC}$ (at one point; derived
  in the second notebook of this chapter).
- **Anticommutator matrix**: for two lists of operators $X_1, \dots, X_n$ and
  $Y_1, \dots, Y_n$ whose anticommutators are numbers, the matrix with entries
  $\{X_i, Y_j\}$.
```

```
- **Independent universes**: two quantum fields $\Psi_1, \Psi_2$ on one state
  space with $\{\Psi_{1A}, \Psi_{2C}^\dagger\} = 0$ and $\{\Psi_{1A}, \Psi_{2C}\} = 0$:
  nothing done to one changes the anticommutation rules of the other.
- **Product Fock space**: the Fock space of the modes of both universes together,
  here $16 + 16 = 32$ fermion modes ($2^{32}$ occupation patterns).
- **Generator**: the operator (or, for one particle, the matrix) that moves a
  system in time; the energy is the generator of time translations.
- **Rank** of a matrix: the number of independent columns; a matrix of rank 16 out
  of 16 has no column that is a combination of the others, in particular it is not 0.
- **Normal-ordered energy**: the energy of a state minus the energy of the vacuum
  (the filled sea), as in the third notebook of this chapter.
- **Status words**: PROVED (exact, for all values), CHECKED (exact or to rounding,
  for the values shown), REPRODUCED (agrees with a Revision record), NOT
  ESTABLISHED (not shown by these equations).
```

```
## 4. The physical and mathematical situation

Everything is at one point of flat 4+4 space (the same equations hold in the
frozen-coefficient model, an ASSUMPTION that leaves out the hidden-direction terms
of the author's field equation), $U = 0$, and with the conventions of the earlier
notebooks of this chapter: $C =
\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, $B = -iC\gamma^{(x_4)}$,
$\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-I_8,
I_8)$, real, symmetric, $\Gamma^2 = I_{16}$.

**Two sign rules.** $\Gamma$ anticommutes with every gamma. Moving $\Gamma$ through
a product of $n$ gammas therefore costs the sign $(-1)^n$:

$$\Gamma C\Gamma = C\ (n = 4),\qquad \Gamma C\gamma^{(x_a)}\Gamma = -C\gamma^{(x_a)}\
(n = 5),\qquad \Gamma B\Gamma = -B\ (n = 5).$$

The mirror matrix $\gamma^{(x_0)}$ commutes with itself and anticommutes with the
four other gammas in $B = -i\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}
\gamma^{(x_4)}$, so $\gamma^{(x_0)}B\gamma^{(x_0)} = (-1)^4B = +B$.

**The Lagrangian identity, line by line.** Insert $\Psi = \Gamma\chi$ (and
$\Psi^\dagger = \chi^\dagger\Gamma$, because $\Gamma$ is real and symmetric) into
$\mathcal{L}_m$:

$$\mathcal{L}_m[\Gamma\chi] = \tfrac12\sum_a(\chi^\dagger\Gamma C\gamma^{(x_a)}
\Gamma\partial_a\chi - \partial_a\chi^\dagger\Gamma C\gamma^{(x_a)}\Gamma\chi) -
m\chi^\dagger\Gamma C\Gamma\chi .$$

Use the two sign rules:

$$\mathcal{L}_m[\Gamma\chi] = -\tfrac12\sum_a(\chi^\dagger C\gamma^{(x_a)}
\partial_a\chi - \partial_a\chi^\dagger C\gamma^{(x_a)}\chi) - m\chi^\dagger C\chi .$$

Take the sign $-1$ out of both terms; the mass term becomes $+m\chi^\dagger C\chi =
-(-m)\chi^\dagger C\chi$, so the bracket is the Lagrangian with mass $-m$:
```

$$\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi] .$$

Three kernels. In $\mathcal{L}_m[\Psi]$ the ∂_4 terms are $\frac12(\Psi^\dagger C\gamma^{(x_4)}\partial_4\Psi - \ldots)$, and $C\gamma^{(x_4)} = iB$, so $N = B$ and $\{\Psi, \Psi^\dagger\} = B^{-1} = B$. The SAME system written in the variable χ has the Lagrangian $\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi]$, whose kernel is $\Gamma B\Gamma = -B$: canonical quantisation of the image gives $\{\chi, \chi^\dagger\} = -B$, which agrees with the map, $\{\Gamma\Psi, (\Gamma\Psi)^\dagger\} = \Gamma B\Gamma = -B$. An INDEPENDENT universe of mass $-m$ has its own Lagrangian $\mathcal{L}_{-m}[\Psi_2]$ with kernel $+B$ (the mass does not enter the kernel), hence $\{\Psi_2, \Psi_2^\dagger\} = +B$. Since $B \neq -B$, the image of universe 1 cannot be such a universe.

Energy and charge. For one plane wave with momenta k_a ($a \neq 4$) the energy of the field is $H = \Psi^\dagger h'_m\Psi$ with $h'_m = mC - i\sum_a k_aC \gamma^{(x_a)}$ (second notebook of this chapter), and its charge is $Q = \Psi^\dagger B\Psi$. Written in the image variable:

$$H = \chi^\dagger\Gamma h'_m\Gamma\chi = \chi^\dagger(mC + i\sum_a k_aC \gamma^{(x_a)})\chi = -\chi^\dagger h'_{-m}\chi,\qquad Q = \chi^\dagger\Gamma B \Gamma\chi = -\chi^\dagger B\chi .$$

So the energy and the charge of the field are MINUS the energy and the charge that the mass $-m$ theory assigns to the image: this is $T \to -T$, $J \to -J$ of T1 as an identity between operators of one system. The image is not a second universe with negative energy; it is the first universe described in other variables.

Two independent universes. On the product Fock space put Ψ_1 (mass m, anticommutator $+B$) and Ψ_2 (mass $-m$, anticommutator $+B$) with $\{\Psi_1, \Psi_2^\dagger\} = 0$. The total energy is $H_1 + H_2$, and its one-particle generator is the block matrix $\mathrm{diag}(Bh'_m, Bh'_{-m})$. At zero momentum $Bh'_{\pm m} = \pm mBC$; since $(BC)^2 = -C\gamma^{(x_4)}CC \gamma^{(x_4)}C = I_{16}$ and $\mathrm{tr}(BC) = 0$, the matrix BC has the eigenvalues $+1$ and -1, eight each, and the block generator has the eigenvalues $+m$ and $-m$, sixteen each: none is 0 for $m \neq 0$. After normal ordering each universe has quanta of energy $+E > 0$ (third notebook of this chapter), so the total energy of every state is at least 0, and equals 0 only in the vacuum. A particle in universe 1 (charge $+1$) and an antiparticle in universe 2 (charge -1) have the total charge 0 but the total energy $2E$.

Text cell:

5. The matrices and the statements of the record

The next cell reads the author's gamma matrices, builds C, Γ and B (exact whole numbers and the imaginary unit '1j'), checks the sign rules of Section 4, and reads the theorem entry Q of the Revision pairing record 'Revision/pairing/pairing-theory.json': its hypothesis and its five statements. Finally it reads the check 'compare.theory.theorem_Q' of the sympy pairing report 'Revision/pairing/reports/python-pairing.json', in which the two verification engines are compared: it says that the 12 Wolfram verifications of theorem Q are confirmed by 10 sympy checks, and names them; the cell confirms these numbers and

that each of the 10 named checks exists with the verdict PASS.

It also defines ‘check_record(condition, name, record)‘: it does what
‘check(condition, name, record=record)‘ of the set-up cell does, but prints the PASS
line and the line naming the reproduced Revision record in one piece (Jupyter
sends printed text to the screen in pieces whose boundaries depend on timing;
printing them in one piece keeps the stored output the same in every run).
Before it checks anything, ‘check_record‘ asks the helper ‘record_says_pass‘ whether
the cited record still says PASS: for a record name of the form
‘<report file>, check <check name>‘ it opens that report (each file once, kept in
the dictionary ‘REPORT_CHECKS‘) and stops the notebook with an error unless a check
of that name exists there with the verdict PASS; a record name without ‘, check ‘
names a data entry that the notebook reads and compares itself.

6. The Lagrangian identity and the three kernels, exactly

The next cell writes the Lagrangian $\mathcal{L}_m$ of Section 3 with SYMBOLS for the 16 components of a field and their derivatives along the eight directions, and for the complex conjugates of all of them (sympy treats a symbol and its conjugate as independent letters, which is exactly how the Lagrangian uses them). The function ‘lagrangian(mass, M)‘ evaluates $\mathcal{L}_{\mathrm{mass}}$ on the field $M\chi$ for a constant matrix M, where χ is the column of symbols. Then the cell

- checks $\mathcal{L}_m[\Gamma\chi] + \mathcal{L}_{-m}[\chi] = 0$ for every value of the 16 components and their 128 derivatives (T1 for flat space, the Lagrangian level);
- reads off the kernel N of each Lagrangian: the coefficient of $\chi_A^*\,\partial_4\chi_C$ is $\frac{i}{2}N_{AC}$, so N_{AC} is $-2i$ times that coefficient;
- checks $N = B$ for $\mathcal{L}_m[\chi]$, $N = -B$ for the image Lagrangian $\mathcal{L}_m[\Gamma\chi]$, $N = +B$ for an independent universe $\mathcal{L}_{-m}[\chi]$, and the anticommutators $N^{-1} = B, -B, B$.

## 7. The field and its two images on a Fock space

The next cell builds the fermionic Fock space of the second notebook of this
chapter, here for any number of modes: a state is a dictionary `{pattern:
amplitude}`, a pattern is a whole number whose binary digit $p$ is the occupation of
mode $p$, `annihilate(p, state)` is $f_p$ and `create(p, state)` is $f_p^*$ (with
the sign $(-1)^{\text{(occupied modes below } p)}$ that makes different modes
anticommute). The field of one universe uses the 16 modes starting at the number
`offset`: $\Psi_A = f_{A - 1 + \mathrm{offset}}$, with the canonical conjugate
$\Psi^\dagger_A = \sum_C f^*_{C - 1 + \mathrm{offset}}B_{CA}$ (the positive
realisation, so that $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$).

For a matrix $M$ the image field is $(M\Psi)_A = \sum_D M_{AD}\Psi_D$ and its
conjugate $((M\Psi)^\dagger)_A = \sum_D \Psi^\dagger_D M^*_{AD}$. The function
```

‘anticommutator_matrix(X, Y, state)‘ returns the matrix with entries
$\langle\phi|\{X_i, Y_j\}|\phi\rangle$ for a normalised state ϕ; when the
anticommutators are numbers (as here), these entries ARE those numbers. The cell
computes it for the image $\Gamma\Psi$ and for the mirror image
$\gamma^{(x_0)}\Psi$.

## 8. One quantum system: $T \to -T$ and $J \to -J$ as operator identities

The next cell takes a mass and a plane wave with momenta along all seven slice
directions (also along the extra times) and builds, on the Fock space, four
operators of the form $X^\dagger NX = \sum_{A,C}X^\dagger_AN_{AC}X_C$:

- the energy of the field, $H_m[\Psi] = \Psi^\dagger h'_m\Psi$, and the energy that
  the mass $-m$ theory assigns to the image, $H_{-m}[\Gamma\Psi] =
  (\Gamma\Psi)^\dagger h'_{-m}(\Gamma\Psi)$;
- the charge of the field, $Q[\Psi] = \Psi^\dagger B\Psi$, and the charge the
  theory assigns to the image, $Q[\Gamma\Psi] = (\Gamma\Psi)^\dagger B(\Gamma\Psi)$.

It checks $H_m[\Psi] = -H_{-m}[\Gamma\Psi]$ and $Q[\Psi] = -Q[\Gamma\Psi]$ by
applying both sides to 150 random states, and records the expectation values for
the figure. Then it checks the quantum equation of motion of the image: with the
energy $H = H_m[\Psi]$ of the system, $[H, (\Gamma\Psi)_c] = -(h_{-m}\Gamma\Psi)_c$
with the mode Hamiltonian $h_{-m} = Bh'_{-m}$, so $i\,\partial_4(\Gamma\Psi) =
h_{-m}\Gamma\Psi$: the image obeys the wave equation of mass $-m$, moved by the
SAME energy operator.
```

## 9. Which images could be an independent universe?

An independently quantised universe of mass $-m$ would be a field $\Psi_2$ with
$\{\Psi_2, \Psi_2^\dagger\} = +B$ (its own Lagrangian, Section 6) that
anticommutes with the first field: $\{\Psi_{2A}, \Psi_C^\dagger\} = 0$ and
$\{\Psi_{2A}, \Psi_C\} = 0$. The next cell tests three candidates built from the
```

```
first field $\Psi$:

- the chirality image $\Gamma\Psi$ (T1);
- the mirror image $\gamma^{(x_0)}\Psi$ (T2, here without the reflection of the
  hidden coordinate, which does not change the anticommutators at one point);
- the conjugate field $\Psi^c = \Gamma\Psi^{\dagger T}$, that is
  $\Psi^c_A = \sum_D\Gamma_{AD}\Psi^\dagger_D$, the conjugation of the quantised
  field that keeps the canonical rule (it reverses the mass; second notebook of
  this chapter).

For each it computes, on the Fock space, its own anticommutator matrix and the two
cross matrices with the first field, and their ranks. Independence would need both
cross matrices to be 0.
```

In [8]:

```

```

Text cell:

```
The result in words. The chirality image has the wrong canonical rule ($-B$
instead of $+B$) AND does not anticommute with the first field (rank 16): it is the
first universe in other variables. The mirror image and the conjugate field have
the right rule $+B$, but they too are built from the operators of the first field
and do not anticommute with it. The rule $+B$ of the mirror image matches the rule
of an independently quantised mirror universe, so such a universe can be quantised
as an ordinary copy (statement Q5 of the record); for the chirality image this is
impossible (statement Q3). A second universe must therefore be a NEW field on a
larger state space, which the next section builds.
```

Text cell:

```
## 10. Two independently quantised universes

The next cell puts universe 1 (mass $+m$) on the modes 0 to 15 and universe 2 (mass
$-m$) on the modes 16 to 31 of one Fock space, each with its own canonical
conjugate. It computes the $32 \times 32$ anticommutator matrix of the combined
list $(\Psi_1, \Psi_2)$ with $(\Psi_1^\dagger, \Psi_2^\dagger)$, which must be
$\mathrm{diag}(B, B)$, and, for comparison, that of the list $(\Psi_1,
\Gamma\Psi_1)$ with its conjugates, which must be the block matrix with $B$,
$B\Gamma$, $\Gamma B$ and $-B$. Then it draws both.
```

## 11. The generators add: no cancellation

The one-particle generator of the two independent universes is the block matrix
$\mathrm{diag}(Bh'_m, Bh'_{-m})$. The next cell computes its exact eigenvalues
with sympy at zero momentum (the record's case: $+m$ and $-m$, 16 times each), and
then, with numbers, its eigenvalues for $m$ from $-3$ to $3$ at zero momentum and
at the good-sector momentum $k_1 = 1.5$. In the second case they are
$\pm\sqrt{m^2 + k_1^2}$ (16 each); in no case is an eigenvalue 0 for $m \neq 0$, so
the total generator is not zero: the two universes do not cancel each other.
```

In [10]:

```
zero_momentum = {k_a: 0 for k_a in k_symbol.values()}
block = sp.diag((B_exact * h_prime_exact(m)).subs(zero_momentum),
```

## 12. One good-sector momentum in both universes

The last computation repeats, for the two universes together, the positive Fock
construction of the third notebook of this chapter, for the recorded good-sector
momentum $m = 2$, $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$ along $(x_0, x_1, x_2, x_3)$,
$E = 5$.
Universe 1 uses the orthonormal eigenvectors $u_s$ ($+E$) and $v_s$ ($-E$) of $h_m$;
universe 2 uses $\Gamma u_s$ and $\Gamma v_s$, which are eigenvectors of $h_{-m} =
\Gamma h_m\Gamma$ with the same eigenvalues. In each universe modes 0 to 7 of its
half are particles and modes 8 to 15 antiparticles (created by $d^*$, so
$\Psi = \sum_s(u_sb_s + v_sd_s^*)$ and $\Psi^\dagger = \chi B$, with $\chi$ the
Hilbert adjoint). The cell checks the canonical rule in both universes, the vacuum
energy $-8E$ of each, that every pattern is an energy and charge eigenstate with
```

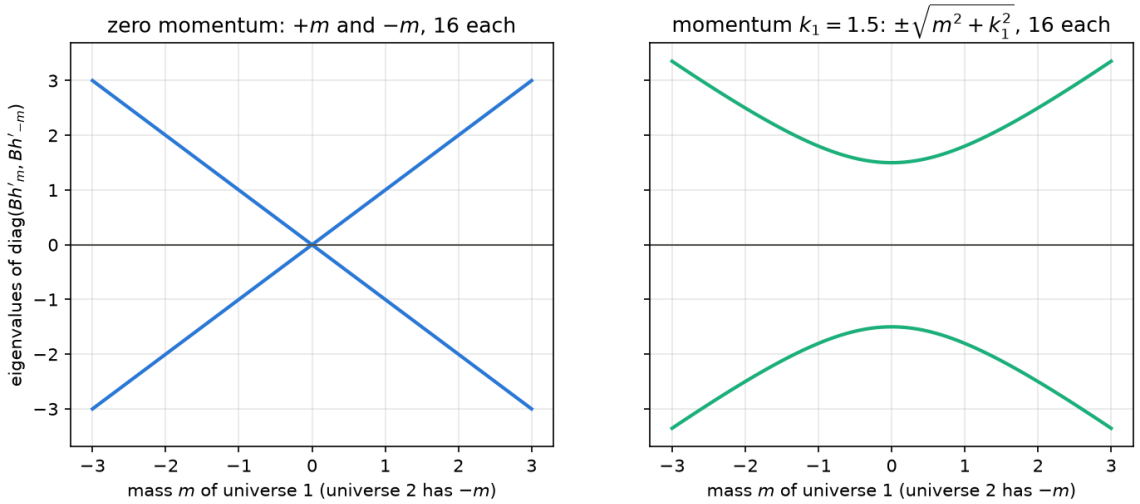

Figure 301: The 32 eigenvalues (vertical axes, units of the momentum and mass) of the one-particle generator $\mathrm{diag}(Bh'_m, Bh'_{-m})$ of two independently quantised universes of masses $+m$ and $-m$, against m from -3 to 3 (horizontal axes); each line carries 16 eigenvalues. Left: zero momentum, eigenvalues $+m$ and $-m$, which vanish only at $m = 0$. Right: the momentum $k_1 = 1.5$, eigenvalues $\pm\sqrt{m^2 + k_1^2}$, never 0. The generators of the two universes add; nothing in them cancels. (Notebook 10g, figure 4.)

```
the normal-ordered total energy $E \times$(number of quanta) and the total charge
(particles minus antiparticles), on 200 random patterns, and the pair state
"particle in universe 1, antiparticle in universe 2". Energy and charge are applied
in the mode form $\chi N\Psi = \sum_{p,q}(W^\dagger NW)_{pq}F_p^*F_q$, where $F_p$
is $b$ or $d^*$ (the same operator as $\sum_{A,C}\chi_AN_{AC}\Psi_C$, but much
faster to apply, because $W^\dagger hW$ is diagonal).
```

## 13. The last check

The last cell checks that all five figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [13]:

```
for name in ("10g_1_krein_metrics.png", "10g_2_one_system.png",
             "10g_3_anticommutator_blocks.png", "10g_4_block_generator.png",
             "10g_5_two_universe_states.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

Out [13]:

```
PASS the figure file 10g_1_krein_metrics.png exists
PASS the figure file 10g_2_one_system.png exists
PASS the figure file 10g_3_anticommutator_blocks.png exists
PASS the figure file 10g_4_block_generator.png exists
PASS the figure file 10g_5_two_universe_states.png exists
ALL 30 CHECKS PASSED (notebook 10g)
```

Text cell:

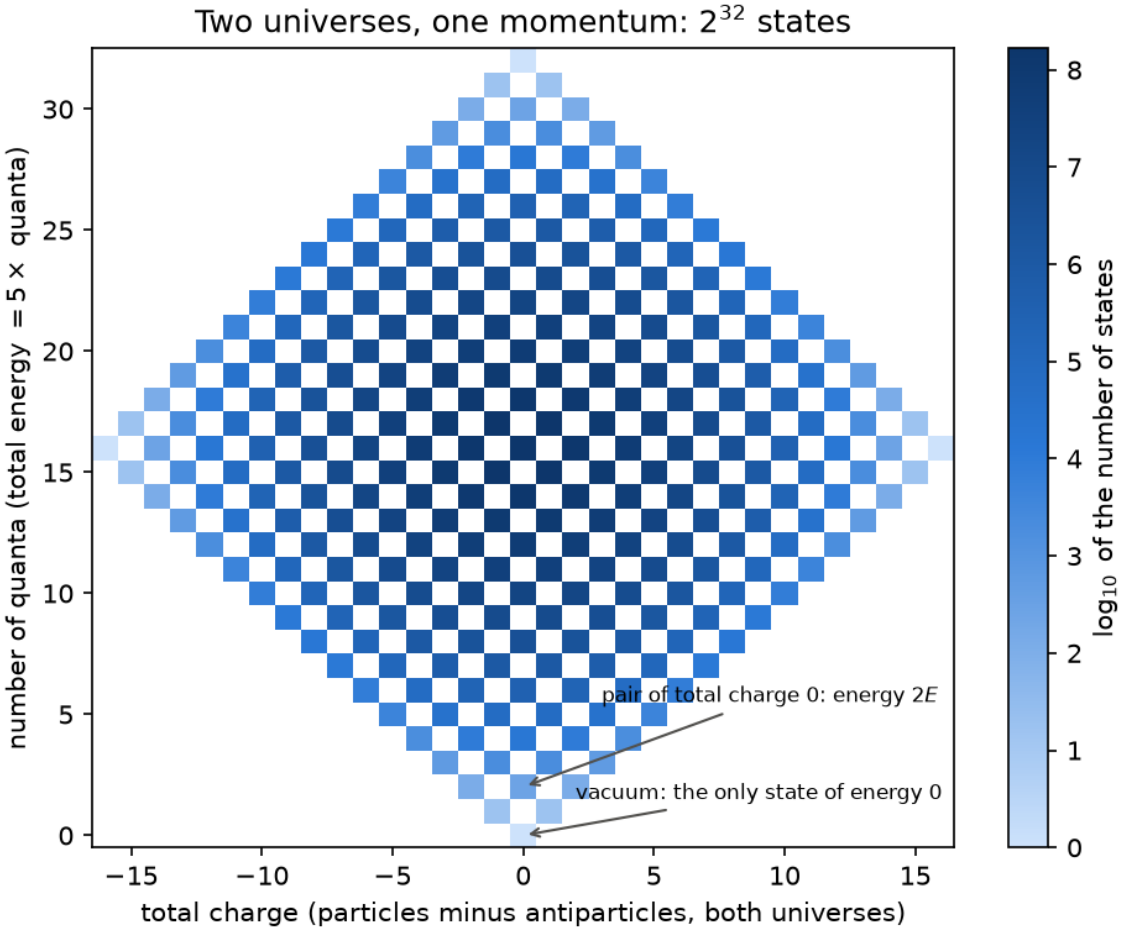

Figure 302: All 2^{32} quantum states of two independently quantised universes of masses $+m$ and $-m$ for one good-sector momentum ($m = 2$, $k = (1, 2, 0, 4)$, $E = 5$ in both), sorted by the total charge (horizontal axis) and the number of quanta (vertical axis; the normal-ordered total energy is 5 times the number of quanta). The colour is the base-10 logarithm of the number of states in each square; white squares are empty. The energies of the two universes add: only the vacuum has total energy 0, every other state has a positive energy, and a pair of total charge 0 (a particle in one universe, an antiparticle in the other) has the energy $2E$, not 0. (Notebook 10g, figure 5.)

```
## 14. What this notebook showed

- PROVED (exactly, for all field values, flat 4+4 space, $U = 0$):
  $\mathcal{L}_m[\Gamma\chi] = -\mathcal{L}_{-m}[\chi]$; the time-derivative kernels
  are $N = B$ for the field, $N = -B$ for its chirality image (the same system in
  the variable $\chi = \Gamma\Psi$) and $N = +B$ for an independent universe of
  mass $-m$, so the canonical rules are $+B$, $-B$ and $+B$ (REPRODUCED: the
  Revision checks of the image metric and of its own quantisation).
- CHECKED on a Fock space: the chirality image carries $-B$, the mirror image keeps
  $+B$; $H_m[\Psi] = -H_{-m}[\Gamma\Psi]$ and $Q[\Psi] = -Q[\Gamma\Psi]$ as
  operators, and the image obeys the wave equation of mass $-m$ under the same
  energy operator. PROVED (exactly): $(-B)(-h'_m) = \Gamma(Bh'_{-m})\Gamma =
  Bh'_m$. So $T \to -T$ and $J \to -J$ of T1 are identities inside ONE quantum
  system: the field and its image are the same universe, and the image is not a
  universe of negative energy.
- CHECKED: an independent second universe must anticommute with the first; the
  chirality image, the mirror image and the conjugate field $\Gamma\Psi^{\dagger T}$
  all fail this (cross anticommutators of rank 16). The chirality image also has
  the wrong rule $-B$, so it cannot be identified with an independently quantised
  mass $-m$ universe (REPRODUCED); a mirror universe has the rule $+B$ of an
  ordinary independent copy.
- CHECKED (32 modes): two independently quantised universes of masses $+m$ and $-m$
  have the rules $+B$ each and anticommute. PROVED (exactly, zero momentum): their
  block generator has the eigenvalues $+m$ and $-m$, 16 each (REPRODUCED);
  COMPUTED: $\pm\sqrt{m^2 + k_1^2}$ with momentum. For one good-sector momentum
  the normal-ordered total energy of every state is $E$ times its number of
  quanta: only the vacuum has energy 0, and a pair of total charge 0 has energy
  $2E$. The energies of two universes ADD; there is no cancellation.
- NOT ESTABLISHED by these computations: that any universe, or any pair of
  universes, is CREATED; any rate, amplitude or mechanism of creation; a positive
  state space for the whole field (the positive Fock spaces here are built for
  single good-sector momenta with frozen coefficients).
```

10.49 Line-by-line walk-through of Notebook 10g

The notebook has 13 code cells, In [1] to In [13]; docstrings are left out of the quotations (they are printed in Section 10.48).

In [1], the set-up cell. Its first 252 lines are comments that repeat the run instructions of Section 10.47. The code is that of In [1] of Notebook 10a (Section 10.10), with the line `NOTEBOOK_ID = "10g" # this notebook: chapter 10, example g`. It prints `Set-up of notebook 10g complete: repository folder found, helpers defined.`

In [2], the matrices and the statements of the record.

```
import contextlib  # lets a block of code print into a text buffer
import io  # the text buffer
import sys  # the screen output, sys.stdout
from math import comb  # comb(8, j): the number of ways to choose j of 8 things

import numpy as np  # numbers, arrays and matrices
import sympy as sp  # exact algebra with symbols
```

```
from matplotlib.colors import LinearSegmentedColormap  # colour scales

REPORT_CHECKS = {}  # report file -> {check name: verdict}; each file is read once

def record_says_pass(record):
    path, separator, check_name = record.partition(", check ")
    if not separator:  # a data entry of a record file that the notebook reads itself
        return True
    if path not in REPORT_CHECKS:
        checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
        REPORT_CHECKS[path] = {c["name"]: c["verdict"].upper() for c in checks}
    return REPORT_CHECKS[path].get(check_name) == "PASS"

def check_record(condition, name, record):
    if not record_says_pass(record):  # the cited check must exist and say PASS
        raise AssertionError("the cited record check is missing or not PASS: " + record)
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # what check prints goes to buffer
        check(condition, name, record=record)
    sys.stdout.write(buffer.getvalue())  # one single piece of output
```

The imports of the earlier notebooks (with the binomial coefficient `comb` of Notebook 10c and the colour scales of Notebook 10a) and the helpers `REPORT_CHECKS`, `record_says_pass` and `check_record` of Section 10.10 (a cited report check must still exist with the verdict PASS; the two printed lines come in one piece).

```
BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
DIVERGING = LinearSegmentedColormap.from_list(
    "blue_grey_red", ["#184f95", "#f0efec", "#e34948"])  # -1 blue, 0 grey, +1 red
```

The colours and the blue-grey-red colour scale of Notebook 10a.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json").read_text(
    encoding="utf-8"))
# gamma[a] is the matrix gamma^(x_a) of the coordinate x_a, a = 1, ..., 8.
gamma = {a: np.array(fixture["gamma"][a], dtype=int) for a in range(8)}
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the author's sigma16
Gamma = (gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5]
         @ gamma[6] @ gamma[7])  # the chirality matrix
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4)
I16 = np.eye(16)
```

The gammas of the record as whole numbers, C, Γ, B and the identity.

```
diagonal = np.array([-1] * 8 + [1] * 8)  # the expected diagonal of Gamma
sign_rules = (np.array_equal(Gamma, np.diag(diagonal))
              and np.array_equal(Gamma @ C @ Gamma, C)
```

```
            and all(np.array_equal(Gamma @ C @ gamma[a] @ Gamma, -C @ gamma[a])
                    for a in range(8)))
check(sign_rules, "Gamma = diag(-I8, I8), Gamma C Gamma = C, Gamma C g^a Gamma = -C g^a")
```

The check confirms $\Gamma = \mathrm{diag}(-I_8, I_8)$ (`np.diag` makes a diagonal matrix from a list) and the two sign rules of Section 10.44.

```
pairing = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                     .read_text(encoding="utf-8"))
theorem_Q = next(t for t in pairing["theorems"] if t["id"] == "Q")
say(f"record entry Q: {theorem_Q['name']}; {len(theorem_Q['hypotheses'])} "
    f"hypothesis, {len(theorem_Q['statement'])} statements")
for number, statement in enumerate(theorem_Q["statement"], 1):
    say(f"Q{number}: {statement[:70]} ...")  # the first 70 characters of each
check(len(theorem_Q["statement"]) == 5, "the record states five quantum statements")
```

The pairing record holds a list of theorems; `next(...)` finds the one whose identifier is `Q`. The cell prints its name, `quantum-level reading`, the number of its hypotheses (1) and of its statements (5), and the first 70 characters of each statement (`statement[:70]`): Q1 about the Krein metric $-B$ of the image, Q2 about the image's own generators, Q3 about an independently quantised universe, Q4 about the one-particle Hamiltonians, Q5 about the mirror image. The check confirms the five statements.

```
compare_file = "Revision/pairing/reports/python-pairing.json"
compare_checks = json.loads(repository_file(compare_file).read_text(
    encoding="utf-8"))["checks"]
detail = next(c["detail"] for c in compare_checks
              if c["name"] == "compare.theory.theorem_Q")
confirming = detail.split("all PASS: ")[1].split(", ")  # the sympy checks named
say("compare.theory.theorem_Q: " + detail.split(" is independently")[0])
say(f"confirmed by {len(confirming)} sympy checks: {confirming[0]}, ...")
check_record("5 statements, 12 Wolfram verifications" in detail
             and "confirmed by 10 sympy checks" in detail and len(confirming) == 10
             and all(record_says_pass(f"{compare_file}, check {name}")
                     for name in confirming),
             "theorem Q: 10 sympy checks, all PASS, confirm 12 Wolfram verifications",
             record=f"{compare_file}, check compare.theory.theorem_Q")
```

The sympy pairing report `python-pairing.json` holds, besides its own checks, checks that compare its results with those of the Wolfram report; `compare.theory.theorem_Q` is the one for theorem Q. The cell reads the report and takes the detail text of that check (`next(...)` returns the first matching entry). The text ends with `all PASS:` and the names of the confirming sympy checks separated by commas: `detail.split("all PASS: ")[1]` is the part after `all PASS:` , and `.split(", ")` cuts it into the list `confirming` of the names. The two `say` lines print the first part of the detail text, `Wolfram theorem Q (quantum-level reading; 5 statements, 12 Wolfram verifications)`, and the number 10 with the first name, `Q.canonical_anticommutator`. The check confirms that the text states 5 statements, 12 Wolfram verifications and 10 sympy checks, that it names exactly 10 checks, and, with `record_says_pass` of In [2], that each of the 10 exists in the report with the verdict PASS; `check_record` itself also confirms the verdict of `compare.theory.t`

heorem_Q. These are the numbers that the table of Section 10.44 quotes. Three PASS lines in the cell.

In [3], the Krein metrics of the two images.

```
image_metric = Gamma @ B @ Gamma.conj().T  # Gamma B Gamma^dagger
mirror_metric = gamma[0] @ B @ gamma[0].conj().T  # gamma0 B gamma0^dagger
signature = np.round(np.linalg.eigvalsh(image_metric)).astype(int)
report("eigenvalues -1 and +1 of Gamma B Gamma^dagger",
       f"{int(np.sum(signature == -1))} and {int(np.sum(signature == 1))}")
```

The anticommutator matrices of the two images (Section 10.15): $\Gamma B \Gamma^\dagger$ and $\gamma^{(x_0)} B (\gamma^{(x_0)})^\dagger$. The eigenvalues of the first are rounded to whole numbers (`astype(int)`) and counted: 8 and 8, so $-B$ also has the signature (8,8).

```
check_record(np.array_equal(image_metric, -B)
             and sorted(signature.tolist()) == [-1] * 8 + [1] * 8,
             "the chirality image Gamma Psi carries the Krein metric -B, (8,8)",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.image_krein_metric")
check_record(np.array_equal(mirror_metric, B),
             "the mirror image gamma^(x0) Psi keeps the Krein metric +B",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.T2_image_keeps_B")
check_record(np.array_equal(image_metric, -B) and np.array_equal(mirror_metric, B),
             "Krein signs: Gamma gives -1, gamma^(x0) gives +1",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_Krein_metric_of_images")
```

Three checks: Q1 and Q5 of the sympy record and the corresponding Wolfram check.

```
def draw_matrix(ax, matrix, title):
    image = ax.imshow(matrix, cmap=DIVERGING, vmin=-1.0, vmax=1.0)
    size = matrix.shape[0]
    step = 3 if size <= 16 else 4  # label every third (or fourth) row and column
    ticks = list(range(0, size, step))
    ax.set_xticks(ticks, [str(t + 1) for t in ticks])
    ax.set_yticks(ticks, [str(t + 1) for t in ticks])
    ax.grid(False)  # no grid lines on top of the squares
    ax.set_title(title)
    return image
```

The heat-map function of In [4] of Notebook 10a (Section 10.10), with one change: for matrices larger than 16×16 (the 32×32 matrices of In [9]) every fourth row and column is labelled.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.2))
draw_matrix(axes[0], B.imag, "field $\\Psi$: $B$")
draw_matrix(axes[1], image_metric.imag,
            "image $\\Gamma\\Psi$: $\\Gamma B\\Gamma^\\dagger = -B$")
image = draw_matrix(axes[2], mirror_metric.imag,
```

```
                    "mirror $\\gamma^{(x_0)}\\Psi$: $+B$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="imaginary part of the entry")
save_figure(fig, "krein_metrics",
...)
```

The three matrices are purely imaginary; their imaginary parts are drawn. Figure 1 of Notebook 10g shows the middle picture as the left one with every red and blue square exchanged ($-B$), and the right picture equal to the left one ($+B$).

In [4], the Lagrangian identity and the three kernels, exactly.

```
g = {a: sp.Matrix(fixture["gamma"][a]) for a in range(8)}  # exact gammas
C_exact = g[0] * g[1] * g[2] * g[3]
Gamma_exact = sp.diag(*[int(x) for x in diagonal])  # diag(-I8, I8), exact
B_exact = -sp.I * C_exact * g[4]
m = sp.Symbol("m", real=True)  # the mass: any real number
```

Exact gammas, C, Γ (`sp.diag` with the 16 whole numbers of the diagonal) and B, and the letter m.

```
field = sp.Matrix(sp.symbols("c1:17"))  # chi_A, A = 1, ..., 16
field_conj = sp.Matrix(sp.symbols("cc1:17"))  # their complex conjugates chi_A^*
# d[a] and d_conj[a]: the derivatives of chi and of chi^* along x_a
d = {a: sp.Matrix(sp.symbols(f"d{a}c1:17")) for a in range(8)}
d_conj = {a: sp.Matrix(sp.symbols(f"d{a}cc1:17")) for a in range(8)}
```

Letters for the 16 components χ_A (`c1` to `c16`), for their complex conjugates (`cc1` to `cc16`), and for the derivatives of both along each of the eight directions (`d1c1` to `d8c16` and `d1cc1` to `d8cc16`): $16 \times 2 + 128 \times 2 = 288$ independent letters. sympy treats a component and its conjugate as independent letters, which is how a Lagrangian uses them.

```
def lagrangian(mass, M):
    psi, psi_conj = M * field, M * field_conj  # M is real: (M chi)^* = M chi^*
    total = sp.Integer(0)
    for a in range(8):
        kinetic = C_exact * g[a]  # the matrix C gamma^(x_a)
        dpsi, dpsi_conj = M * d[a], M * d_conj[a]
        total += sp.Rational(1, 2) * ((psi_conj.T * kinetic * dpsi)[0]
                                      - (dpsi_conj.T * kinetic * psi)[0])
    total -= mass * (psi_conj.T * C_exact * psi)[0]
    return sp.expand(total)
```

`lagrangian(mass, M)` evaluates $\mathcal{L}_{\text{mass}}$ of Section 10.44 on the field $M\chi$ for a constant real matrix M: the column of conjugates of $M\chi$ is $M\chi^*$, and the row $(M\chi)^\dagger$ is its transpose, written `psi_conj .T`. For each direction the kinetic term $\frac{1}{2}((M\chi)^\dagger C\gamma^{(x_a)}\partial_a(M\chi) - \partial_a(M\chi)^\dagger C\gamma^{(x_a)}M\chi)$ is added (`+=`), then the mass term is subtracted (`-=`), and the result is multiplied out.

```
def kernel(expression):
    return sp.Matrix(16, 16, lambda A, C_: -2 * sp.I * expression.coeff(
        field_conj[A] * d[4][C_]))
```

The kernel N is read off the terms $\frac{i}{2} N_{AC} \chi^*_A \partial_4 \chi_C$: `expression.coeff(...)` returns the coefficient of the product $\chi^*_A \, \partial_4 \chi_C$ in the expanded Lagrangian, and N_{AC} is $-2i$ times it (because $-2i \cdot \frac{i}{2} = 1$).

```
L_field = lagrangian(m, sp.eye(16))  # L_m[chi]
L_image = lagrangian(m, Gamma_exact)  # L_m[Gamma chi]: the same system, new variables
L_independent = lagrangian(-m, sp.eye(16))  # L_-m[chi]: an independent universe
say(f"number of terms of L_m[chi]: {len(L_field.args)}")
identity_ok = sp.expand(L_image + L_independent) == 0
check(identity_ok, "exact: L_m[Gamma chi] = -L_-m[chi] for all components and "
                   "derivatives")
```

The three Lagrangians of Section 10.44: of the field, of its chirality image (the same system in the variable χ), and of an independent universe of mass $-m$. The expanded Lagrangian of the field has 272 terms (`.args` lists the terms of a sum). The check proves $\mathcal{L}_m[\Gamma\chi] + \mathcal{L}_{-m}[\chi] = 0$ for all values of the 288 letters.

```
N_field, N_image, N_independent = map(kernel, (L_field, L_image, L_independent))
kernels_ok = (N_field == B_exact and N_image == -B_exact
              and N_independent == B_exact)
say(f"kernels equal to B: field {N_field == B_exact}, image {N_image == B_exact}, "
    f"independent universe {N_independent == B_exact}; image kernel = -B: "
    f"{N_image == -B_exact}")
check_record(kernels_ok,
             "kernels: N = B (field), N = -B (image), N = +B (independent universe)",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_symplectic_kernel_grassmann")
```

`map(kernel, ...)` applies `kernel` to each of the three Lagrangians. The printed line shows the kernels equal to B for the field and the independent universe (`True`), not for the image (`False`), whose kernel is $-B$ (`True`). The check reproduces the Wolfram record check `Q_symplectic_kernel_grassmann`.

```
anticommutators = [N.inv() for N in (N_field, N_image, N_independent)]
check_record(anticommutators[0] == B_exact and anticommutators[1] == -B_exact
             and anticommutators[2] == B_exact,
             "canonical rules N^(-1): {Psi,Psi^dag} = B, {chi,chi^dag} = -B, +B",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.image_own_quantisation")
```

The canonical rules are the inverses of the kernels (Section 10.12): B, $-B$ and $+B$. Three PASS lines in the cell.

In [5], the field and its two images on a Fock space.

```
def sign_below(n, p):
    return -1 if bin(n & ((1 << p) - 1)).count("1") % 2 else 1

def annihilate(p, state):
```

```
    result = {}
    for n, amplitude in state.items():
        if n >> p & 1:  # mode p is occupied in the pattern n
            new = n ^ (1 << p)  # the same pattern with mode p emptied
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result

def create(p, state):
    result = {}
    for n, amplitude in state.items():
        if not n >> p & 1:  # mode p is empty in the pattern n
            new = n | (1 << p)  # the same pattern with mode p filled
            result[new] = result.get(new, 0) + sign_below(n, p) * amplitude
    return result
```

The Fock space of In [3] of Notebook 10b (Section 10.19): the sign $(-1)^s$, f_p and f_p^*. Nothing in these functions limits the number of modes, so they work for the 32 modes used below.

```
def add(*terms):
    result = {}
    for coefficient, state in terms:
        for n, amplitude in state.items():
            result[n] = result.get(n, 0) + coefficient * amplitude
    return result

def inner(left, right):
    return sum(np.conj(a) * right.get(n, 0) for n, a in left.items())

def largest(state):
    return max((abs(a) for a in state.values()), default=0.0)
```

Combinations of states, the positive inner product and the largest amplitude, as in Notebook 10b.

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed

def random_state(patterns, modes):
    state = {}
    for n in rng.integers(0, 2 ** modes, size=patterns):
        state[int(n)] = complex(rng.normal(), rng.normal())
    length = np.sqrt(inner(state, state).real)
    return {n: a / length for n, a in state.items()}
```

A normalised random state of a few patterns, as in Notebook 10b, now for any number of modes.

```
def field_op(offset):
    return [lambda s, A=A: annihilate(A - 1 + offset, s) for A in range(1, 17)]
```

```
def conjugate_op(offset):
    return [lambda s, A=A: add(*[(B[C_ - 1, A - 1], create(C_ - 1 + offset, s))
                                 for C_ in range(1, 17) if B[C_ - 1, A - 1] != 0])
            for A in range(1, 17)]
```

`field_op(offset)` returns the 16 operators $\Psi_A = f_{A-1+\text{offset}}$ of one universe whose modes start at `offset`, as a list of functions; `conjugate_op(offset)` the canonical conjugates $\Psi_A^\dagger = \sum_C f^*_{C-1+\text{offset}} B_{CA}$ (the positive realisation of Section 10.14). Each `lambda s, A=A: ...` is a small function of a state `s`; the default value `A=A` stores the current value of `A` in each function (without it all 16 functions would use the last value of the loop).

```
def mapped(M, ops):
    return [lambda s, A=A: add(*[(M[A - 1, D - 1], ops[D - 1](s))
                                 for D in range(1, 17) if M[A - 1, D - 1] != 0])
            for A in range(1, 17)]

def mapped_conjugate(M, conj_ops):
    return mapped(M.conj(), conj_ops)
```

`mapped(M, ops)` returns the 16 operators $(MX)_A = \sum_D M_{AD} X_D$ of an image; `mapped_conjugate(M, conj_ops)` its conjugate $((M\Psi)^\dagger)_A = \sum_D \Psi_D^\dagger M^*_{AD}$, which is `mapped` with the conjugate matrix applied to the conjugate operators.

```
def anticommutator_matrix(X, Y, state):
    result = np.zeros((len(X), len(Y)), dtype=complex)
    for i, x in enumerate(X):
        for j, y in enumerate(Y):
            both = add((1, x(y(state))), (1, y(x(state))))
            result[i, j] = inner(state, both)
    return result
```

For two lists of operators the matrix of the numbers $\langle\phi|\{X_i, Y_j\}\phi\rangle$; for a normalised state ϕ and anticommutators that are numbers, these entries ARE the anticommutators.

```
Psi, Psi_dagger = field_op(0), conjugate_op(0)  # one universe: modes 0, ..., 15
phi = random_state(6, 16)
own_rule = anticommutator_matrix(Psi, Psi_dagger, phi)
image_rule = anticommutator_matrix(mapped(Gamma, Psi),
                                   mapped_conjugate(Gamma, Psi_dagger), phi)
mirror_rule = anticommutator_matrix(mapped(gamma[0], Psi),
                                    mapped_conjugate(gamma[0], Psi_dagger), phi)
errors = [np.max(np.abs(own_rule - B)), np.max(np.abs(image_rule + B)),
          np.max(np.abs(mirror_rule - B))]
report("largest deviations from B, -B and +B", ", ".join(f"{e:.1e}" for e in errors))
check(max(errors) < 1e-12,
      "Fock space: {Psi, Psi^dag} = B, image -B, mirror +B (256 entries each)")
```

One universe on the modes 0 to 15 and a random normalised state. The three 16×16 anticommutator matrices of the field, of its chirality image and of its mirror image are compared with B, $-B$ and $+B$; the deviations are printed as `2.2e-16` each, rounding only.

In [6], one quantum system: $T \to -T$ and $J \to -J$ as operator identities.

```
m_value = 1.3  # any mass and momenta (here with momenta along the extra times too)
k = {0: 1.1, 1: 0.4, 2: -0.7, 3: 0.2, 5: 0.9, 6: -0.3, 7: 0.5}

def h_prime(mass):
    return mass * C - 1j * sum(k_a * (C @ gamma[a]) for a, k_a in k.items())
```

The mass and the momenta of In [4] of Notebook 10b, and the energy matrix $h'_{\text{mass}} = \text{mass}\, C - i \sum_a k_a C \gamma^{(x_a)}$ of Section 10.12.

```
def bilinear(X_dagger, N, X, state):
    terms = []
    for C_ in range(16):
        lowered = X[C_](state)
        if lowered:
            terms += [(N[A, C_], X_dagger[A](lowered)) for A in range(16)
                      if N[A, C_] != 0]
    return add(*terms)
```

`bilinear(X_dagger, N, X, state)` applies $\sum_{A,C} X^\dagger_A N_{AC} X_C$ to a state: for each C it applies X_C once and then every $X^\dagger_A$ with $N_{AC} \neq 0$.

```
image_field = mapped(Gamma, Psi)  # Gamma Psi
image_conjugate = mapped_conjugate(Gamma, Psi_dagger)  # (Gamma Psi)^dagger
worst_H, worst_Q, values = 0.0, 0.0, []
for _ in range(150):
    state = random_state(4, 16)
    H_field = bilinear(Psi_dagger, h_prime(m_value), Psi, state)
    H_image = bilinear(image_conjugate, h_prime(-m_value), image_field, state)
    Q_field = bilinear(Psi_dagger, B, Psi, state)
    Q_image = bilinear(image_conjugate, B, image_field, state)
```

For 150 random states the four operators of Section 10.44 are applied: the energy of the field $H_m[\Psi] = \Psi^\dagger h'_m \Psi$, the energy that the mass $-m$ theory assigns to the image $H_{-m}[\Gamma\Psi]$, the charge $Q[\Psi] = \Psi^\dagger B \Psi$ and the charge assigned to the image $Q[\Gamma\Psi]$.

```
    worst_H = max(worst_H, largest(add((1, H_field), (1, H_image))))
    worst_Q = max(worst_Q, largest(add((1, Q_field), (1, Q_image))))
    values.append([inner(state, X).real for X in (H_field, H_image, Q_field,
                                                  Q_image)])
values = np.array(values)  # columns: <H_m[Psi]>, <H_-m[Gamma Psi]>, <Q>, <Q image>
report("largest |(H_m[Psi] + H_-m[Gamma Psi]) phi| over 150 states", f"{worst_H:.1e}")
report("largest |(Q[Psi] + Q[Gamma Psi]) phi| over 150 states", f"{worst_Q:.1e}")
```

```
check_record(worst_H < 1e-12 and worst_Q < 1e-12,
             "operators: H_m[Psi] = -H_-m[Gamma Psi] and Q[Psi] = -Q[Gamma Psi]",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_generators_of_the_image_grassmann")
```

The sums $(H_m[\Psi] + H_{-m}[\Gamma\Psi])\phi$ and $(Q[\Psi] + Q[\Gamma\Psi])\phi$ must vanish; the largest amplitudes are printed as `0.0e+00`. The expectation values are kept for the figure. The check reproduces the Wolfram record check `Q_generators_of_the_image_grassmann`: Q2 as an operator identity.

```
h_mode_minus = B @ h_prime(-m_value)  # the mode Hamiltonian of mass -m
worst = 0.0
for c_ in range(16):
    H_after = bilinear(Psi_dagger, h_prime(m_value), Psi, image_field[c_](phi))
    H_before = image_field[c_](bilinear(Psi_dagger, h_prime(m_value), Psi, phi))
    commutator = add((1, H_after), (-1, H_before))  # [H, (Gamma Psi)_c] phi
    expected = add(*[(-h_mode_minus[c_, d_], image_field[d_](phi))
                     for d_ in range(16)])
    worst = max(worst, largest(add((1, commutator), (-1, expected))))
report("largest violation of [H, (Gamma Psi)_c] = -(h_-m Gamma Psi)_c", f"{worst:.1e}")
check(worst < 1e-12, "the image obeys i d4 (Gamma Psi) = h_-m Gamma Psi under the "
                     "same H")
```

With the energy $H = H_m[\Psi]$ of the system, the commutator $[H, (\Gamma\Psi)_c]$ must equal $-(h_{-m}\Gamma\Psi)_c$ with $h_{-m} = Bh'_{-m}$; by the Heisenberg equation (Section 10.12) this is $i\,\partial_4(\Gamma\Psi) = h_{-m}\Gamma\Psi$. The largest violation is printed as `1.6e-17`. Two PASS lines in the cell.

In [7], the same exactly, and a picture.

```
k_symbol = {a: sp.Symbol(f"k{a}", real=True) for a in (0, 1, 2, 3, 5, 6, 7)}

def h_prime_exact(mass):
    result = mass * C_exact
    for a, k_a in k_symbol.items():
        result = result - sp.I * k_a * C_exact * g[a]
    return result
```

Real letters for the seven momenta, and the exact energy matrix h'_{mass}.

```
zero = sp.zeros(16, 16)
own_data = (-B_exact) * (-h_prime_exact(m))  # the image: metric -B, energy -h'_m
by_map = Gamma_exact * (B_exact * h_prime_exact(-m)) * Gamma_exact
same = ((own_data - by_map).applyfunc(sp.expand) == zero
        and (own_data - B_exact * h_prime_exact(m)).applyfunc(sp.expand) == zero)
energy_rule = (Gamma_exact * h_prime_exact(m) * Gamma_exact
               + h_prime_exact(-m)).applyfunc(sp.expand) == zero
check_record(same and energy_rule,
             "exact: (-B)(-h'_m) = Gamma (B h'_-m) Gamma = B h'_m; "
             "Gamma h'_m Gamma = -h'_-m",
             record="Revision/pairing/reports/python-pairing.json, check "
                    "Q.image_generators_same_dynamics")
```

The identities of Q2, exactly for all masses and momenta, in the direction in which the record states them: `own_data` is the generator of the image of a field of mass $-m$, which carries the metric $-B$ and the energy matrix $-h'_m$ (the comment of the line says so), and `by_map` is the generator Bh'_{-m} of that field carried over by Γ. The check confirms $(-B)(-h'_m) = \Gamma(Bh'_{-m})\Gamma = Bh'_m$, and $\Gamma h'_m \Gamma = -h'_{-m}$. Since m is a symbol, replacing m by $-m$ gives the direction of Section 10.44: the image of the field of mass m evolves by $(-B)(-h'_{-m}) = Bh'_{-m} = h_{-m}$. The check reproduces the sympy record check `Q.image_generators_same_dynamics`.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.4))
panels = ((axes[0], 0, 1, BLUE, "energy",
           "$\\langle H_m[\\Psi]\\rangle$", "$\\langle H_{-m}[\\Gamma\\Psi]\\rangle$"),
          (axes[1], 2, 3, ORANGE, "charge",
           "$\\langle Q[\\Psi]\\rangle$", "$\\langle Q[\\Gamma\\Psi]\\rangle$"))
```

Two panels; for each, the tuple names the drawing area, the two columns of `values` to plot, a colour, a word and the two axis labels.

```
for ax, x_col, y_col, colour, what, x_label, y_label in panels:
    ax.plot(values[:, x_col], values[:, y_col], "o", color=colour, markersize=4,
            label="150 random states")
    low, high = values[:, x_col].min() - 0.5, values[:, x_col].max() + 0.5
    ax.plot([low, high], [-low, -high], color=GREY, linewidth=1,
            label="the line $y = -x$")
    ax.set_xlabel(f"{what} of the field, {x_label}")
    ax.set_ylabel(f"{what} given to the image, {y_label}")
    ax.legend(fontsize=8)
axes[0].set_title("$T \\to -T$ inside one system")
axes[1].set_title("$J \\to -J$ inside one system")
save_figure(fig, "one_system",
...)
```

Each state is a dot at (value of the field, value given to the image), and the grey line is $y = -x$. Figure 2 of Notebook 10g shows all 150 dots exactly on the line $y = -x$ in both panels: the reversal of the energy and of the charge under T1 is an identity between operators of ONE quantum system, not a statement about a second universe.

In [8], which images could be an independent universe?

```
conjugate_field = mapped(Gamma, Psi_dagger)  # Psi^c_A = sum_D Gamma_AD Psi^dag_D
# Its canonical conjugate: (Psi^c)^dagger_A = sum_D conj(Gamma_AD) Psi_D, by the
# rule (Psi^dagger)^dagger = Psi of the canonical relations (Gamma is real).
conjugate_field_dagger = mapped(Gamma, Psi)
```

The conjugate field $\Psi^c = \Gamma\Psi^{\dagger T}$ of Section 10.15 and, as the comment lines say, its canonical conjugate $\sum_D \Gamma_{AD}\Psi_D$ (Γ is real, and the conjugate of $\Psi^\dagger$ is Ψ).

```
candidates = {
    "Gamma Psi": (image_field, image_conjugate),
    "gamma0 Psi": (mapped(gamma[0], Psi), mapped_conjugate(gamma[0], Psi_dagger)),
```

```
    "Psi^c = Gamma Psi^dag T": (conjugate_field, conjugate_field_dagger),
}
phi = random_state(6, 16)
results = {}
```

The three candidates of Section 10.44, each with its operators and their conjugates, and a new random state.

```
for label, (X, X_dagger) in candidates.items():
    metric = anticommutator_matrix(X, X_dagger, phi)  # {X_A, X_C^dagger}
    cross_1 = anticommutator_matrix(X, Psi_dagger, phi)  # {X_A, Psi^dagger_C}
    cross_2 = anticommutator_matrix(X, Psi, phi)  # {X_A, Psi_C}
    sign = (1 if np.allclose(metric, B) else -1 if np.allclose(metric, -B) else 0)
    ranks = (np.linalg.matrix_rank(cross_1), np.linalg.matrix_rank(cross_2))
    results[label] = (sign, ranks, cross_1, cross_2)
    say(f"{label:24s} metric {sign:+d} B; rank of {{X, Psi^dag}} = {ranks[0]:2d}, "
        f"rank of {{X, Psi}} = {ranks[1]:2d}")
```

For each candidate: its own anticommutator matrix (its sign, $+1$ for B and -1 for $-B$), and the two cross matrices with the first field, with their ranks. In an f-string a doubled brace prints a single brace. The printed lines show: $\Gamma\Psi$ with the metric $-B$ and the ranks 16 and 0; $\gamma^{(x_0)}\Psi$ with $+B$ and the ranks 16 and 0; Ψ^c with $+B$ and the ranks 0 and 16. Independence would need both ranks to be 0; every candidate has a cross matrix of rank 16.

```
chirality = results["Gamma Psi"]
conjugate = results["Psi^c = Gamma Psi^dag T"]
check_record(chirality[0] == -1 and chirality[1] == (16, 0)
             and np.allclose(chirality[2], Gamma @ B),
             "Gamma Psi: metric -B and {Gamma Psi, Psi^dag} = Gamma B of rank 16",
             record="Revision/pairing/reports/wolfram-pairing.json, check "
                    "Q_no_identification_of_independent_universes")
check_record(conjugate[0] == 1 and conjugate[1] == (0, 16)
             and np.allclose(conjugate[3], -Gamma @ B),
             "Psi^c keeps +B (Gamma B^T Gamma^dag = B) but {Psi^c, Psi} = -Gamma B",
             record="Revision/lead_checks/reports/charge-conjugation-and-u1.json, "
                    "check quantum_charge_conjugation_unitary_type")
check(results["gamma0 Psi"][0] == 1 and results["gamma0 Psi"][1] == (16, 0),
      "gamma0 Psi keeps +B; as an operator of the same field it is not independent")
```

Three checks: the chirality image has $-B$ and $\{\Gamma\Psi, \Psi^\dagger\} = \Gamma B$ (Q3, reproducing `Q_no_identification_of_independent_universes`); the conjugate field keeps $+B$ but $\{\Psi^c, \Psi\} = -\Gamma B$ (reproducing `quantum_charge_conjugation_unitary_type`); the mirror image keeps $+B$ but is built from the same field.

In [9], two independently quantised universes.

```
Psi_1, Psi_1_dagger = field_op(0), conjugate_op(0)  # universe 1: modes 0..15
Psi_2, Psi_2_dagger = field_op(16), conjugate_op(16)  # universe 2: modes 16..31
phi_32 = random_state(6, 32)
two_universes = anticommutator_matrix(Psi_1 + Psi_2, Psi_1_dagger + Psi_2_dagger,
```

```
                                    phi_32)
image_pair = anticommutator_matrix(
    Psi_1 + mapped(Gamma, Psi_1),
    Psi_1_dagger + mapped_conjugate(Gamma, Psi_1_dagger), phi_32)
```

Universe 1 lives on the modes 0 to 15 and universe 2 on the modes 16 to 31 of one Fock space of 32 modes, each with its own canonical conjugate; `phi_32` is a random state of 32 modes. The `+` of two lists of operators joins them into a list of 32. `two_universes` is the 32×32 anticommutator matrix of (Ψ_1, Ψ_2) with their conjugates; `image_pair` the same for a field and its chirality image.

```
zero_16 = np.zeros((16, 16))
expected_two = np.block([[B, zero_16], [zero_16, B]])
expected_image = np.block([[B, B @ Gamma], [Gamma @ B, -B]])
cross_zero = np.max(np.abs(anticommutator_matrix(Psi_1, Psi_2, phi_32)))
report("largest |{Psi_1, Psi_2}| (must be 0)", f"{cross_zero:.1e}")
check(np.allclose(two_universes, expected_two) and cross_zero < 1e-12
      and np.allclose(image_pair, expected_image),
      "two universes: diag(B, B); field and image: blocks B, B Gamma, Gamma B, -B")
```

`np.block` assembles a matrix from blocks. The expected matrices are $\mathrm{diag}(B, B)$ for two universes, and the blocks B, $B\Gamma$, ΓB, $-B$ for a field and its image (Section 10.44: $\{\Psi, (\Gamma\Psi)^\dagger\} = B\Gamma$ because $(\Gamma\Psi)^\dagger = \Psi^\dagger\Gamma$). The largest $\{\Psi_1, \Psi_2\}$ is printed as `0.0e+00`: the two universes anticommute.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 5.0))
draw_matrix(axes[0], two_universes.imag,
            "independent: $(\\Psi_1, \\Psi_2)$")
image = draw_matrix(axes[1], image_pair.imag,
                    "one field and its image: $(\\Psi_1, \\Gamma\\Psi_1)$")
for ax in axes:
    ax.axhline(15.5, color=GREY, linewidth=1)  # the border between the two halves
    ax.axvline(15.5, color=GREY, linewidth=1)
fig.colorbar(image, ax=list(axes), shrink=0.75, label="imaginary part of the entry")
save_figure(fig, "anticommutator_blocks",
...)
```

The two 32×32 matrices as heat maps, with grey lines between the halves. Figure 3 of Notebook 10g shows on the left two copies of B on the diagonal and empty off-diagonal blocks (two independent universes), and on the right a lower right block $-B$ and full off-diagonal blocks (a field and its image are one system).

In [10], the generators add.

```
zero_momentum = {k_a: 0 for k_a in k_symbol.values()}
block = sp.diag((B_exact * h_prime_exact(m)).subs(zero_momentum),
                (B_exact * h_prime_exact(-m)).subs(zero_momentum))
block_eigenvalues = block.eigenvals()  # {eigenvalue: how often}
say(f"exact eigenvalues of diag(B h'_m, B h'_-m) at k = 0: +m "
    f"{block_eigenvalues.get(m, 0)} times, -m {block_eigenvalues.get(-m, 0)} times, "
    f"{len(block_eigenvalues)} different values")
check_record(block_eigenvalues == {m: 16, -m: 16},
```

```
        "block generator at k = 0: eigenvalues +m and -m, 16 each, none zero",
        record="Revision/pairing/reports/python-pairing.json, check "
               "Q.no_cancellation_independent_universes")
```

At zero momentum (every momentum letter replaced by 0) the function `sp.diag` assembles the exact block generator $\mathrm{diag}(Bh'_m, Bh'_{-m})$ from its two 16×16 blocks, and the method `eigenvals` returns its exact eigenvalues, each with its multiplicity. The printed line shows $+m$ 16 times and $-m$ 16 times (2 different values), as Section 10.44 derived. The check reproduces the record check `Q.no_cancellation_independent_universes` of the sympy pairing report.

```
def block_numbers(mass, k1):
    def energy(mu):  # the energy matrix of mass mu and momentum k1
        return mu * C - 1j * k1 * (C @ gamma[1])
    top, bottom = B @ energy(mass), B @ energy(-mass)
    values = np.concatenate([np.linalg.eigvals(top), np.linalg.eigvals(bottom)])
    return np.sort(values.real)
```

The 32 eigenvalues of the block generator as numbers, for a mass and a momentum k_1 along x_1: the inner function `energy` is h'_μ, and the eigenvalues of the two blocks are joined and sorted.

```
masses = np.linspace(-3.0, 3.0, 121)
spectra_0 = np.array([block_numbers(x, 0.0) for x in masses])
spectra_k = np.array([block_numbers(x, 1.5) for x in masses])
formula_k = np.sqrt(masses ** 2 + 1.5 ** 2)
error_k = max(np.max(np.abs(spectra_k[:, 16:] - formula_k[:, None])),
              np.max(np.abs(spectra_k[:, :16] + formula_k[:, None])))
report("largest deviation from +-sqrt(m^2 + k1^2), 16 each", f"{error_k:.1e}")
check(error_k < 1e-10 and np.min(np.abs(spectra_k)) >= 1.5 - 1e-10,
      "with k1 = 1.5 the 32 eigenvalues are +-sqrt(m^2 + k1^2): never 0")
```

For 121 masses from -3 to 3, at zero momentum and at $k_1 = 1.5$: with the momentum the 16 largest eigenvalues must be $+\sqrt{m^2 + k_1^2}$ and the 16 smallest $-\sqrt{m^2 + k_1^2}$; the largest deviation is printed as `4.9e-15`, and no eigenvalue is smaller in size than $k_1 = 1.5$.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharey=True)
axes[0].plot(masses, spectra_0[:, [0, 31]], color=BLUE, linewidth=2)
axes[0].set_title("zero momentum: $+m$ and $-m$, 16 each")
axes[1].plot(masses, spectra_k[:, [0, 31]], color=GREEN, linewidth=2)
axes[1].set_title("momentum $k_1 = 1.5$: $\\pm\\sqrt{m^2 + k_1^2}$, 16 each")
for ax in axes:
    ax.axhline(0.0, color=GREY, linewidth=1)
    ax.set_xlabel("mass $m$ of universe 1 (universe 2 has $-m$)")
axes[0].set_ylabel("eigenvalues of diag$(Bh'_m, Bh'_{-m})$")
save_figure(fig, "block_generator",
...)
```

The smallest and the largest eigenvalue (columns 0 and 31; each carries 16) against the mass. Figure 4 of Notebook 10g shows on the left the two straight lines $\pm m$, crossing only at $m = 0$, and on the

right the two branches $\pm\sqrt{m^2 + 2.25}$, which never reach 0: the generators of the two universes add, and nothing in them cancels.

In [11], one good-sector momentum in both universes.

```
def orthonormal_columns(P):
    basis = []
    for column in P.T:
        v = column.astype(complex)
        for _ in range(2):  # the second pass removes rounding errors
            for e in basis:
                v = v - (e.conj() @ v) * e
        length = np.sqrt((v.conj() @ v).real)
        if length > 1e-8:
            basis.append(v / length)
    return np.array(basis).T

def mode_hamiltonian(mass, momenta):
    h = -1j * mass * gamma[4]
    for a, k_a in momenta.items():
        h = h - k_a * (gamma[4] @ gamma[a])
    return h
```

The Gram-Schmidt function (Section 10.19) and the mode Hamiltonian of Section 10.3, as in the earlier notebooks.

```
sample = {0: 4, 1: 1, 2: 2}  # the recorded good-sector momentum, with m = 2
h_plus, h_minus = mode_hamiltonian(2, sample), mode_hamiltonian(-2, sample)
E = 5.0  # sqrt(4 + 1 + 4 + 16)
W1 = np.hstack([orthonormal_columns((I16 + h_plus / E) / 2),
                orthonormal_columns((I16 - h_plus / E) / 2)])  # u_1..u_8, v_1..v_8
W2 = Gamma @ W1  # the eigenvectors of h_-m = Gamma h_m Gamma
check(np.allclose(h_minus @ W2[:, :8], E * W2[:, :8])
      and np.allclose(h_minus @ W2[:, 8:], -E * W2[:, 8:])
      and np.allclose(W2.conj().T @ W2, I16),
      "Gamma u_s and Gamma v_s are orthonormal eigenvectors of h_-m, energies +-E")
```

The recorded good-sector momentum $m = 2$, $k = (k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $E = 5$. Universe 1 uses the orthonormal eigenvectors u_s and v_s of h_m (Section 10.20); universe 2 uses Γu_s and Γv_s, which are eigenvectors of $h_{-m} = \Gamma h_m \Gamma$ with the same eigenvalues ($h_{-m}\Gamma u = \Gamma h_m u = E\,\Gamma u$) and orthonormal ($\Gamma$ keeps lengths). The check confirms both.

```
def universe(W, offset):
    def F(p, s):  # b (particle modes p < 8) or d^* (antiparticle modes p >= 8)
        return annihilate(p + offset, s) if p < 8 else create(p + offset, s)

    def F_star(p, s):  # the Hilbert adjoint of F_p
        return create(p + offset, s) if p < 8 else annihilate(p + offset, s)
```

`universe(W, offset)` builds the positive realisation of one universe whose 16 modes start at `offset`. The inner functions `F` and `F_star` are those of In [4] of Notebook 10c (Section 10.26): F_p is b for the particle modes and d^* for the antiparticle modes, and `F_star` its Hilbert adjoint.

```
    psi = [lambda s, A=A: add(*[(W[A, p], F(p, s)) for p in range(16)])
           for A in range(16)]  # Psi_A = sum_p W_Ap F_p
    chi = [lambda s, A=A: add(*[(np.conj(W[A, p]), F_star(p, s)) for p in range(16)])
           for A in range(16)]  # chi_A = sum_p conj(W_Ap) F_p^*
    psi_dagger = mapped(B.T, chi)  # Psi^dagger_A = sum_C chi_C B_CA
    return psi, chi, psi_dagger, F, F_star
```

The field $\Psi_A = \sum_p W_{Ap} F_p$, its Hilbert adjoint χ_A and the canonical conjugate $\Psi^\dagger_A = \sum_C \chi_C B_{CA}$, written as `mapped(B.T, chi)` because $\sum_C (B^T)_{AC} \chi_C = \sum_C \chi_C B_{CA}$. (Here the components are counted from 0, so `W[A, p]` has no `- 1`.) The function returns the three lists and the two mode functions.

```
def mode_bilinear(W, F, F_star, N, state):
    M = W.conj().T @ N @ W
    terms = []
    for q in range(16):
        lowered = F(q, state)
        if lowered:
            terms += [(M[p, q], F_star(p, lowered)) for p in range(16)
                      if abs(M[p, q]) > 1e-12]
    return add(*terms)
```

`mode_bilinear` applies $\chi N \Psi = \sum_{p,q} (W^\dagger N W)_{pq} F^*_p F_q$, the function `bilinear` of In [4] of Notebook 10c; it is much faster than the sum over the components because $W^\dagger h W$ is diagonal.

```
psi_1, chi_1, psi_1_dagger, F_1, F_1_star = universe(W1, 0)
psi_2, chi_2, psi_2_dagger, F_2, F_2_star = universe(W2, 16)
phi_32 = random_state(4, 32)
rule_1 = anticommutator_matrix(psi_1, psi_1_dagger, phi_32)
rule_2 = anticommutator_matrix(psi_2, psi_2_dagger, phi_32)
rule_12 = anticommutator_matrix(psi_1, psi_2_dagger, phi_32)
check(np.allclose(rule_1, B) and np.allclose(rule_2, B) and np.allclose(rule_12, 0),
      "positive realisation: {Psi_1, Psi_1^dag} = {Psi_2, Psi_2^dag} = B, cross 0")
```

The two universes on the modes 0 to 15 and 16 to 31. The check confirms the canonical rule B in each and the cross anticommutator 0.

```
def total_energy(state):
    return add((1, mode_bilinear(W1, F_1, F_1_star, h_plus, state)),
               (1, mode_bilinear(W2, F_2, F_2_star, h_minus, state)))

def total_charge(state):
    return add((1, mode_bilinear(W1, F_1, F_1_star, I16, state)),
               (1, mode_bilinear(W2, F_2, F_2_star, I16, state)))
```

The total energy $H_1 + H_2$ (with $H = \chi h \Psi$ in each universe, Section 10.20) and the total charge $Q_1 + Q_2$ (with $Q = \chi \Psi$).

```
VACUUM = {0: 1.0}
vacuum_energy = inner(VACUUM, total_energy(VACUUM)).real
vacuum_charge = inner(VACUUM, total_charge(VACUUM)).real
report("vacuum energy and charge of the two universes",
       f"{vacuum_energy:.10f} and {vacuum_charge:.10f}")
check_record(abs(vacuum_energy + 16 * E) < 1e-9 and abs(vacuum_charge - 16) < 1e-9,
             "each universe has the sea energy -8E = -40 (total -80) and charge 8",
             record="Revision/theory/reports/python-field-theory.json, check "
                    "good_sector_positive_fock_realisation")
```

The vacuum of both universes has the energy $-80 = 2 \times (-40)$ and the charge $16 = 2 \times 8$ before normal ordering; the check reproduces the record check `good_sector_positive_fock_realisation` for each universe. Three PASS lines in the cell.

In [12], the states of the two universes.

```
def quanta_and_charge(n):
    groups = [bin((n >> shift) & 0xFF).count("1") for shift in (0, 8, 16, 24)]
    b_1, d_1, b_2, d_2 = groups  # particles and antiparticles of each universe
    return b_1 + d_1 + b_2 + d_2, b_1 - d_1 + b_2 - d_2
```

The 32 binary digits of a pattern fall into four groups of 8: the particles and the antiparticles of universe 1, then those of universe 2. For each group the pattern is shifted to the right by 0, 8, 16 or 24 places, the eight lowest digits are kept (`& 0xFF`) and their ones are counted. The function returns the number of quanta and the total charge (particles minus antiparticles).

```
eigen_ok = True
for n in rng.integers(0, 2 ** 32, size=200):
    n = int(n)
    quanta, charge = quanta_and_charge(n)
    state = {n: 1.0}
    eigen_ok = eigen_ok and largest(add(
        (1, total_energy(state)), (-(E * quanta + vacuum_energy), state))) < 1e-9
    eigen_ok = eigen_ok and largest(add(
        (1, total_charge(state)), (-(charge + vacuum_charge), state))) < 1e-9
check(eigen_ok, "200 random patterns: energy E (quanta) - 16E, charge (b - d) + 16")
```

For 200 random patterns the total energy and charge are applied, and the results compared with the pattern times $E \times (\text{quanta}) - 16E$ and times $(\text{charge}) + 16$: every pattern is an eigenstate, with the normal-ordered total energy E times its number of quanta.

```
pair = create(24, create(0, VACUUM))  # b_1^* (mode 0), then d_2^* (mode 24)
pair_energy = inner(pair, total_energy(pair)).real - vacuum_energy
pair_charge = inner(pair, total_charge(pair)).real - vacuum_charge
report("pair state: normal-ordered total energy and total charge",
       f"{pair_energy:.10f} and {pair_charge:.10f}")
```

```
check(abs(pair_energy - 2 * E) < 1e-9 and abs(pair_charge) < 1e-9,
      "a particle in universe 1 and an antiparticle in universe 2: charge 0, "
      "energy 2E")
```

The pair state: a particle in universe 1 (mode 0) and an antiparticle in universe 2 (mode 24, the first antiparticle mode of universe 2). Its normal-ordered total energy is printed as $10.0000000000 = 2E$ and its total charge as 0: the energies of the two universes add.

```
counts = np.zeros((33, 33), dtype=np.int64)  # rows: quanta, columns: charge + 16
for b_1 in range(9):
    for d_1 in range(9):
        for b_2 in range(9):
            for d_2 in range(9):
                number = comb(8, b_1) * comb(8, d_1) * comb(8, b_2) * comb(8, d_2)
                counts[b_1 + d_1 + b_2 + d_2, b_1 - d_1 + b_2 - d_2 + 16] += number
```

All $2^{32} = 4294967296$ patterns are counted by formula, not one by one: for given numbers b_1, d_1, b_2, d_2 of occupied modes in the four groups there are $\binom{8}{b_1}\binom{8}{d_1}\binom{8}{b_2}\binom{8}{d_2}$ patterns, added in the square (number of quanta, charge +16). `np.int64` holds whole numbers up to about 9×10^{18}.

```
zero_energy_states = int(counts[0].sum())
zero_charge_lowest = min(q for q in range(33) if q > 0 and counts[q, 16] > 0)
report("number of patterns", int(counts.sum()))
report("patterns of zero normal-ordered energy", zero_energy_states)
report("fewest quanta of a non-vacuum state of total charge 0", zero_charge_lowest)
check(counts.sum() == 2 ** 32 and zero_energy_states == 1 and zero_charge_lowest == 2,
      "only the vacuum has energy 0; charge 0 needs at least 2 quanta (energy 2E)")
```

The printed numbers: 4294967296 patterns, 1 of zero energy (the vacuum), and 2 as the smallest positive number of quanta of a state of total charge 0 (column 16): a state of charge 0 other than the vacuum has at least the energy $2E$. Three PASS lines in the cell.

```
fig, ax = plt.subplots(figsize=(7.5, 5.6))
shown = np.where(counts > 0, np.log10(np.maximum(counts, 1)), np.nan)  # NaN: empty
light_to_dark = LinearSegmentedColormap.from_list(
    "light_to_dark_blue", ["#cde2fb", "#2a78d6", "#0d366b"])
image = ax.imshow(shown, origin="lower", cmap=light_to_dark, aspect="auto",
                  extent=(-16.5, 16.5, -0.5, 32.5))
ax.annotate("vacuum: the only state of energy 0", (0, 0), xytext=(2.0, 1.5),
            fontsize=8, arrowprops={"arrowstyle": "->", "color": GREY})
ax.annotate("pair of total charge 0: energy $2E$", (0, 2), xytext=(3.0, 5.5),
            fontsize=8, arrowprops={"arrowstyle": "->", "color": GREY})
ax.set_xlabel("total charge (particles minus antiparticles, both universes)")
ax.set_ylabel("number of quanta (total energy $= 5 \\times$ quanta)")
ax.set_title("Two universes, one momentum: $2^{32}$ states")
ax.grid(False)
fig.colorbar(image, ax=ax, label="$\\log_{10}$ of the number of states")
save_figure(fig, "two_universe_states",
...)
```

The heat map of In [9] of Notebook 10c, now for two universes: the logarithm of the counts, white for empty squares, with arrows at the vacuum and at the pairs of total charge 0. Figure 5 of Notebook 10g shows a diamond of states from charge -16 to 16 and up to 32 quanta, with a single state at energy 0 and nothing below it: two independently quantised universes of masses $+m$ and $-m$ have energies that add; nothing cancels.

In [13], the last check.

```
for name in ("10g_1_krein_metrics.png", "10g_2_one_system.png",
             "10g_3_anticommutator_blocks.png", "10g_4_block_generator.png",
             "10g_5_two_universe_states.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The five figure files exist, and the last line prints ALL 30 CHECKS PASSED (notebook 10g): the five figure checks and the 25 checks of the cells before (3 in In [2], 3 each in In [3], In [4], In [8], In [11] and In [12], 1 each in In [5], In [7] and In [9], and 2 each in In [6] and In [10]).

10.50 What we proved, what we computed, what we assumed

Proved. Exactly, for all values of the letters involved, each with the Revision record that verifies it and the notebook that reproduces it:

statement	where it is verified	notebook
$B = -iC\gamma^{(x_4)}$ is purely imaginary and Hermitian, $BB = I_{16}$, $\mathrm{tr}\, B = 0$, signature (8,8); it commutes with the gammas of x_1, x_2, x_3, x_4, x_0 and anticommutes with those of x_5, x_6, x_7	`python-field-theory.json`, check `B_properties`; `wolfram-algebra.json`, check `B_signature_8_8`; `python-algebra.json`, check `B_gamma_relations`	10a, 10e
the local conservation law $\partial_\mu(\cos z\, J^\mu) = 0$ on shell; the charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, d^7x$ is an indefinite (Krein) form (it is constant in time only when no charge flows through the boundary of the slice, which at $z = \pi/2$ is an ASSUMED no-flux condition that the record does not impose)	`charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity`; `wolfram-field-theory.json`, check `charge_density_is_Krein_form_G`	none

statement	where it is verified	notebook
one plane wave: $hh = w^2 I_{16}$, $Bh = h^\dagger B$ (the Krein form is conserved, also by growing waves); h Hermitian and $[B, h] = 0$ exactly in the good sector	`wolfram-pairing.json`, check `Q_one_particle_flat_dispersion`; `python-field-theory.json`, checks `mode_hamiltonian_B_selfadjoint_dispersion` and `good_sector_spectrum_and_B_sectors`; `wolfram-field-theory.json`, checks `mode_hamiltonian_good_sector` and `mode_hamiltonian_Krein_selfadjoint`	10a
waves with $w^2 < 0$ grow, with rates that have no upper bound	`python-field-theory.json`, check `extra_time_modes_grow`; `python-scope.json`, check `extra_time_growth_rates_unbounded`	10a, 10f
Theorem 10.1: Krein inertia (4,4) of every real-frequency eigenspace; Krein-neutral eigenspaces at imaginary and zero frequency	`wolfram-pairing.json`, checks `Q_one_particle_Krein_inertia_real_frequencies` and `Q_one_particle_complex_and_zero_frequencies_Krein_neutral`; `python-pairing.json`, checks `Q.one_particle_Krein_inertia_proof` and `Q.one_particle_complex_frequency_Krein_neutral`	10a, 10f
$\Gamma h_m \Gamma = h_{-m}$ and $\gamma^{(x_0)} h_m(k) \gamma^{(x_0)} = h_{-m}(R_0 k)$: identical one-particle spectra for $+m$ and $-m$	`python-pairing.json` and `wolfram-pairing.json`, check `Q.one_particle_maps` / `Q_one_particle_maps`	10a, 10f
the canonical rule $\{\Psi_A(x), \Psi^\dagger_C(y)\} = B_{AC}\, \delta^7(x-y)/\cos z$; the Heisenberg equation is the field equation	`python-field-theory.json`, check `canonical_anticommutator_B`; `wolfram-field-theory.json`, checks `first_order_form_and_anticommutator` and `Heisenberg_equation_reproduces_field_equation`	10b

statement	where it is verified	notebook
Theorem 10.2: no positive inner product with $\Psi^\dagger$ the Hilbert adjoint; the state space is a Krein space with fundamental symmetry B	`python-field-theory.json` and `wolfram-field-theory.json`, check `no_positive_inner_product`	10b
the expectation-value rule $\epsilon_n u_n^\dagger M u_n$ (Krein-Fock), $u^\dagger B M u$ and $-v^\dagger B M v$ (positive realisation)	`python-field-theory.json`, checks `expectation_value_rule` and `good_sector_positive_fock_realisation`	10b, 10c
the 17 signs of $MBM^\dagger = \sigma B$; the conjugation $\Psi \to \Gamma \Psi^{\dagger T}$ keeps B and reverses the mass, $M = I_{16}$ gives $-B$	`pairing-theory.json`, data `Krein_signs_M_B_Mdagger`; `charge-conjugation-and-u1.json`, check `quantum_charge_conjugation_unitary_type`	10b, 10g
good sector, one momentum with frozen coefficients: positive Fock space with $\Psi^\dagger = \chi B$, vacuum $-8E$, quanta $+E$, charges ± 1	`python-field-theory.json`, check `good_sector_positive_fock_realisation`; `wolfram-field-theory.json`, check `Fock_space_good_sector_example`	10c, 10f, 10g
the classical commuting field dirac16complex00 has an energy unbounded below and an indefinite charge	`python-scope.json`, check `commuting_field_energy_unbounded_below`	10c
$\lambda \neq 0$, in the finite Fock model of one good-sector mode set with frozen coefficients (16 modes; symbolic λ; at rest with symbolic m, and $m = 3$, $k = (4,0,0,0)$): $:\sum_\mu K_\mu: = :(m + U'(S))S:$ and, at rest, $\hat{\rho} = :mS + U:$, $\hat{p} = :SU' - U:$ are exact operator identities for solutions of the interacting operator field equation if and only if U and $\hat{T}$ are Wick ordered	`fock-quartic.json`, checks `trace_identity_operator_identity_wick`, `trace_identity_fails_for_every_other_combination` and `homogeneous_rho_p_operator_identities_wick`	none

statement	where it is verified	notebook
curved good sector: symmetric, and the Krein form conserved, only up to the boundary term $\partial_0(\sin z\, u^\dagger M_0 v)$; flux $2i$; role of $3H\gamma^{(x_0)}$; x_0-independent waves grow for $m^2 < 9H^2$; the exact solution	`python-scope.json`, checks `good_sector_hermiticity_up_to_the_brane_flux` and `good_sector_x0_independent_modes_without_boundary_condition`; `wolfram-field-theory.json`, checks `good_sector_hermiticity_curved` and `Krein_form_conserved_curved`; `python-field-theory.json`, check `exact_solution_family_x4_x0`	10d
the invariant forms are $r_- CP_- + r_+ CP_+$; every invariant charge density is indefinite; exactly the 21 generators without x_4 keep B (Spin(4,3))	`python-algebra.json`, checks `spin_commutant_dimension_2` and `S_preserves_C_and_commutes_with_Gamma`; `wolfram-algebra.json`, checks `S_preserves_C` and `S_preserves_B_only_off_x4`	10e
along the deflating history (local-frame model): $h(x_4)^2 = w(x_4)^2 I_{16}$, $\|h_A\| = k_5$, $\|Bh - hB\| = 2k_5$; every wave with extra-time momentum reaches the onset time $\ln X^*/(2AH)$; the good sector stays Hermitian	this chapter, Section 10.39 (the book's own derivation, exact in sympy)	10f

statement	where it is verified	notebook
the quantum reading Q1 to Q5 of the pairing	`wolfram-pairing.json`, checks `Q_Krein_metric_of_images`, `Q_symplectic_kernel_grassmann`, `Q_generators_of_the_image_grassmann`, `Q_no_identification_of_independent_universes`; `python-pairing.json`, checks `Q.image_krein_metric`, `Q.image_own_quantisation`, `Q.image_generators_same_dynamics`, `Q.no_cancellation_independent_universes`, `Q.T2_image_keeps_B`, `compare.theorem_Q`	10g

Computed. Numerical results of the notebooks, with their accuracy:

- Notebook 10a: the 16 eigenvalues of h agree with $\pm w$ to 3.6×10^{-15}; in the scan across the threshold the inertia is $(4, 4, 0)$ at all 110 real-frequency points and $(0, 0, 8)$ at all 137 imaginary-frequency points, with the smallest nonzero Gram eigenvalue 0.2225 below the threshold.
- Notebook 10b: the canonical rule holds on the Fock space exactly (0.0) and the Heisenberg equation to 1.6×10^{-17}; the Krein norms of 5000 random unit columns lie between -0.777 and 0.704; for the boosted mode the rule $\epsilon u^\dagger M u$ holds to 1.3×10^{-15}, while $u^\dagger B M u$ misses by up to 5.82.
- Notebook 10c: vacuum -40, every quantum $+5$, charges ± 1 (to 10^{-12}), for $m = 2$, $k = (k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$ and for $m = 3$, $k_1 = 4$; the 65536 states of one momentum, one of them of energy 0; the commuting field: densities ± 5, and from -4.364 to 4.333 for 4000 random waves.
- Notebook 10d: the Krein charge of the exact growing solution rises from 1/6 to 454.007 between $x_4 = 0$ and 1.5 and equals the flux added up over time to a relative 6.7×10^{-7}; the late growth slope 5.6600 approaches $2k = 5.6569$.
- Notebook 10e: exactly two zero eigenvalues of $M^T M$ (at most 1.3×10^{-15}) below the smallest nonzero one, 7.0.
- Notebook 10f: the onset time 2.996044 of the wave $q_1 = 0.5$, $q_5 = 0.05$ (agreement with bisection 8.9×10^{-16} for 48 waves); onset times from 6.9078 to 0.0941 for $10^{-3} \le q_5 \le 1$; the good-sector energies at the five slices (for $q_1 = 1$ from 1.414214 down to 1.009116).

- Notebook 10g: the pair of total charge 0 in two independent universes has the normal-ordered energy $10 = 2E$; of the $2^{32} = 4294967296$ states of one momentum in both universes exactly one (the vacuum) has energy 0.

Assumed.

- Anticommutators (not commutators) for dirac16complex: part of its definition as a fermion field; no spin-statistics theorem for signature (4,4) is proved.
- Normal ordering: a prescription that drops the energy $-8E$ of the filled sea per momentum.
- Flat 4+4 space, or the frozen-coefficient model of Section 10.3 (the coefficients of one point and one instant, without the two hidden-direction terms of the author's field equation, among them the spin-connection term $3H\gamma^{(x_0)}$; keeping that term breaks $Bh = h^\dagger B$), for the one-particle statements and the Fock spaces; the good sector itself is a restriction imposed by hand (no mechanism that removes the extra-time waves is derived).
- The deflating history $a_4 = AHx_4$ ($A = H = m = 1$) is a PRESCRIBED BACKGROUND, and the local-frame model of Section 10.39 evaluates the coefficients at one instant and one hidden position (`parameters.json`; `ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`).
- The Z2 brane condition at $z = \pi/2$ is ASSUMED by the Kohn-Sham record (Chapter 14); the quantisation of this chapter imposes no boundary condition there. The total charge Q is constant in time only under such an ASSUMED no-flux condition at $z = \pi/2$; what is proved is its local conservation law (Section 10.2).

Hypothesis. That the big bang creates universes in pairs of masses $+m$ and $-m$ is the author's HYPOTHESIS; no equation of this chapter describes a creation, in pairs or otherwise (Section 10.45).

Open.

- A positive Hilbert space for the whole quantised field (all momenta, the curved metric), and the quantisation of the extra-time sector, whose waves grow and become Krein-neutral along the deflating history.
- A boundary condition at the patch end $z = \pi/2$ that makes the curved good-sector evolution Hermitian and conserves the Krein charge.
- The interacting theory $\lambda \neq 0$, in particular the operator form of the on-shell identity of the energy-momentum tensor beyond the finite model of one good-sector mode set with frozen coefficients (where it holds with Wick ordering only, Section 10.21): for the field on a whole slice, with the curved x_0 dependence and in the extra-time sector; symmetry and conservation of the quartic operator are not verified.
- The evolution of the quantum state through the changing background (whether the instantaneous vacuum of one time contains quanta of a later time).
- Any creation process, rate or amplitude for universes, which these equations do not contain.

10.51 Exercises

Exercise 10.1. Use the table of B in Section 10.2. (a) Compute Be_1 and Be_{10}, where e_j is the unit column with 1 in place j. (b) Find the two columns $u = ae_1 + be_{10}$ of length 1 that are eigenvectors of B, with their eigenvalues. (c) Compute the Krein norms of e_1 and of the two eigenvectors.

Exercise 10.2. For each wave compute w^2, say whether it oscillates, grows linearly or grows exponentially, and give the growth rate where there is one: (a) $m = 2$, $k_1 = 1$, $k_6 = 2$; (b) $m = 1$, $k_0 = 1$, $k_5 = 1$, $k_7 = 1$; (c) $m = 1$, $k_5 = 3$. In case (a), what is the Krein inertia of the eigenspaces?

Exercise 10.3. A two-dimensional model of a Krein space: $B = \mathrm{diag}(1, -1)$ and $h = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. (a) Show $h^\dagger B = Bh$ and $hh = -I_2$. (b) Solve $i\,du/dt = hu$ with $u(0) = (1, 0)$. (c) Compute $u^\dagger u$ and $u^\dagger Bu$ as functions of t.

Exercise 10.4. A toy Dirac sea: one positive level (operator b, energy E) and one negative level (operator d^*, energy $-E$), with $\{b, b^*\} = \{d, d^*\} = 1$ and all other anticommutators 0, have $H = E\,b^*b - E\,dd^*$ and $Q = b^*b + dd^*$. (a) Find the vacuum energy and charge before normal ordering. (b) Write $:H:$ and $:Q:$. (c) Give the normal-ordered energy and charge of $b^*|0\rangle$, $d^*|0\rangle$ and $b^*d^*|0\rangle$.

Exercise 10.5. For one good-sector momentum (8 particle and 8 antiparticle modes, energy E per quantum), count the states (a) with 2 quanta, (b) with 2 quanta and charge 0, (c) with 8 quanta and charge 0, (d) in all.

Exercise 10.6. Using only $(\gamma^{(x_a)})^\dagger = \eta_{aa}\gamma^{(x_a)}$, $\gamma^{(x_a)}\gamma^{(x_a)} = \eta_{aa} I_{16}$, the commutation of B with the gammas (Section 10.2) and $\Gamma B \Gamma = -B$, compute the sign σ in $MBM^\dagger = \sigma B$ for $M = \gamma^{(x_5)}$, $M = \gamma^{(x_4)}$ and $M = P_5 = \Gamma\gamma^{(x_5)}$.

Exercise 10.7. (a) Show that $S^{(x_1x_5)} = \frac{1}{2}\gamma^{(x_1)}\gamma^{(x_5)}$ is Hermitian and anticommutes with B, so that it is Krein-unitary but not unitary. (b) Show that $S^{(x_4x_1)} = \frac{1}{2}\gamma^{(x_4)}\gamma^{(x_1)}$ is Hermitian and commutes with B, and compute its Krein defect $S^\dagger B + BS$.

Exercise 10.8. On the deflating history with $A = H = m = 1$ and $y = 0$: (a) find the onset time of the waves with $q_1 = 0$ and $q_5 = 0.05$, and $q_5 = 0.001$; (b) at what time does the wave $q_1 = 0$, $q_5 = 0.05$ reach the frame momentum $k_5 = 2$? (c) Compute X^* and the onset time for $q_1 = 0.5$, $q_5 = 0.05$, and explain why it is later than in (a).

Exercise 10.9. For the good-sector waves that do not depend on x_0 (Section 10.28), with $H = 1$: find the eigenvalues of A and the growth rate for $m = 2$ and for $m = 4$.

10.52 Answers to the exercises

Answer 10.1. (a) $(Be_1)_r = B_{r1}$, the entries of column 1: by the table only row 10 has its nonzero entry in column 1, with the value $-i$, so $Be_1 = -ie_{10}$. Row 1 has its entry $+i$ in column 10, so $Be_{10} = ie_1$. (b) For $u = ae_1 + be_{10}$, $Bu = aBe_1 + bBe_{10} = ib\,e_1 - ia\,e_{10}$, by (a). $Bu = \lambda u$ means $ib = \lambda a$ and $-ia = \lambda b$. The first gives $b = -i\lambda a$ (multiply by $-i$); insert it into the second: $-ia = \lambda(-i\lambda a) = -i\lambda^2 a$, so $\lambda^2 = 1$. For $\lambda = +1$: $b = -ia$, and with length 1, $u_+ = (e_1 - ie_{10})/\sqrt{2}$. For $\lambda = -1$: $b = ia$, $u_- = (e_1 + ie_{10})/\sqrt{2}$. Check: $Bu_- = (i \cdot i\,e_1 - ie_{10})/\sqrt{2} = (-e_1 - ie_{10})/\sqrt{2} = -u_-$. (c) $e_1^\dagger Be_1 = B_{11} = 0$: the unit column e_1 has length 1 but Krein norm 0. $u_\pm^\dagger Bu_\pm = \pm u_\pm^\dagger u_\pm = \pm 1$.

Answer 10.2. $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$ (Section 10.4). (a) $w^2 = 4+1-4 = 1$: the frequencies ± 1 are real and the wave oscillates, although h is not Hermitian ($k_6 \neq 0$). By Theorem 10.1 both eigenspaces have the Krein inertia $(4,4)$. (b) $w^2 = 1+1-1-1 = 0$ with $h \neq 0$: $hh = 0$, $e^{-ihx_4} = I_{16} - ihx_4$, and the wave grows linearly unless $hu(0) = 0$; the range of h is Krein-neutral. (c) $w^2 = 1 - 9 = -8$: $w = \pm i\sqrt{8} = \pm 2\sqrt{2}\, i$, half of the waves grow like $e^{2\sqrt{2}\, x_4}$ (rate $2\sqrt{2} \approx 2.828$), and both eigenspaces are Krein-neutral.

Answer 10.3. (a) $h^\dagger = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ (transpose; the entries are real). $h^\dagger B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ (the second column of $h^\dagger$ is multiplied by -1) and $Bh = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ (the second row of h is multiplied by -1): equal. $hh = \begin{pmatrix} 0\cdot 0 + 1\cdot(-1) & 0\cdot 1 + 1\cdot 0 \\ (-1)\cdot 0 + 0\cdot(-1) & (-1)\cdot 1 + 0\cdot 0 \end{pmatrix} = -I_2$, so $w^2 = -1$. (b) As in Section 10.4, $e^{-iht} = \cos(wt) I_2 - i\frac{\sin(wt)}{w} h$ with $w = i$; $\cos(it) = \cosh t$ and $\sin(it)/i = \sinh t$, so $e^{-iht} = \cosh t\, I_2 - i \sinh t\, h$. With $hu(0) = (0, -1)$ (the first column of h): $u(t) = (\cosh t, i \sinh t)$. Check: $i\, du/dt = i(\sinh t, i\cosh t) = (i\sinh t, -\cosh t)$ and $hu = (i\sinh t, -\cosh t)$. (c) $u^\dagger u = \cosh^2 t + \sinh^2 t = \cosh 2t$, which grows; $u^\dagger B u = \cosh^2 t - \sinh^2 t = 1$, constant: the Krein norm is conserved by a growing wave, as Section 10.4 proved for dirac16complex.

Answer 10.4. (a) The vacuum has $b|0\rangle = d|0\rangle = 0$. With $dd^* = 1 - d^*d$: $H = E\, b^*b + E\, d^*d - E$ and $Q = b^*b - d^*d + 1$, so the vacuum has the energy $-E$ (the filled negative level) and the charge 1. (b) $:H: = E(b^*b + d^*d)$ and $:Q: = b^*b - d^*d$. (c) $b^*|0\rangle$: energy E, charge $+1$; $d^*|0\rangle$: energy E, charge -1; $b^*d^*|0\rangle$: energy $2E$, charge 0. A state of total charge 0 other than the vacuum has a positive energy, as for the two universes of Section 10.44.

Answer 10.5. A state is fixed by the set of occupied modes; with N_b particles and N_d antiparticles it has $N_b + N_d$ quanta and the charge $N_b - N_d$ (Section 10.20). (a) Any 2 of the 16 modes: $\binom{16}{2} = \frac{16\cdot 15}{2} = 120$; split as $\binom{8}{2} = 28$ (two particles, charge 2), $8 \cdot 8 = 64$ (one of each, charge 0) and 28 (two antiparticles, charge -2). (b) 64. (c) $N_b = N_d = 4$: $\binom{8}{4}\binom{8}{4} = 70 \cdot 70 = 4900$, the largest group of Figure 3 of Notebook 10c. (d) $2^{16} = 65536$.

Answer 10.6. $M = \gamma^{(x_5)}$: it is time-like, so $(\gamma^{(x_5)})^\dagger = -\gamma^{(x_5)}$ and $\gamma^{(x_5)}\gamma^{(x_5)} = -I_{16}$, and it anticommutes with B: $\gamma^{(x_5)} B (\gamma^{(x_5)})^\dagger = -\gamma^{(x_5)} B \gamma^{(x_5)} = B\gamma^{(x_5)}\gamma^{(x_5)} = -B$, $\sigma = -1$. $M = \gamma^{(x_4)}$: time-like and commuting with B: $\gamma^{(x_4)} B (\gamma^{(x_4)})^\dagger = -\gamma^{(x_4)} B \gamma^{(x_4)} = -B\gamma^{(x_4)}\gamma^{(x_4)} = B$, $\sigma = +1$. $M = P_5$: $P_5 B P_5^\dagger = \Gamma\gamma^{(x_5)} B (\gamma^{(x_5)})^\dagger \Gamma^\dagger = \Gamma(-B)\Gamma = -\Gamma B \Gamma = B$, $\sigma = +1$. These are the signs of the record (Section 10.15).

Answer 10.7. (a) $(\gamma^{(x_1)}\gamma^{(x_5)})^\dagger = (\gamma^{(x_5)})^\dagger (\gamma^{(x_1)})^\dagger = (-\gamma^{(x_5)})\gamma^{(x_1)} = \gamma^{(x_1)}\gamma^{(x_5)}$, so $S = S^{(x_1 x_5)}$ is Hermitian, $S^\dagger = S$ (and not anti-Hermitian, so $\exp(\theta S)$ is not unitary). $\gamma^{(x_1)}$ commutes and $\gamma^{(x_5)}$ anticommutes with B, so $SB = -BS$. The Krein condition: $S^\dagger B + BS = SB + BS = -BS + BS = 0$. (b) $(\gamma^{(x_4)}\gamma^{(x_1)})^\dagger = \gamma^{(x_1)}(-\gamma^{(x_4)}) = \gamma^{(x_4)}\gamma^{(x_1)}$: Hermitian; both gammas commute with B, so $SB = BS$. Then $S^\dagger B + BS = 2BS = -iC\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_1)} = iC\gamma^{(x_1)} \neq 0$, the defect of the record check `S_preserves_B_only_off_x4`.

Answer 10.8. (a) For $q_1 = 0$, $y = 0$: $x_4^* = \ln(m/q_5)/(AH) = \ln(1/q_5)$; $\ln 20 = 2.995732$ for $q_5 = 0.05$, and $\ln 1000 = 6.907755$ for $q_5 = 0.001$. (b) $k_5 = 0.05\, e^{x_4} = 2$ gives $e^{x_4} = 40$, $x_4 = \ln 40 = 3.688879$, where the eigenvalues are $\pm i\sqrt{3}$ (Notebook 10f, In [7]). (c) With $c = 1$: $X^* = (1 + \sqrt{1 + 4 \cdot 0.25 \cdot 0.0025})/(2 \cdot 0.0025) = (1 + \sqrt{1.0025})/0.005 = 400.249844$, and $x_4^* = \frac{1}{2}\ln 400.249844 = 2.996044$, the value of Notebook 10f, In [6]. It is later than $\ln 20$ because the

3-space momentum adds $k_1^2 > 0$ to w^2, so the growing k_5^2 needs a little longer to overcome $m^2 + k_1^2$.

Answer 10.9. $AA = (m^2 - 9H^2)I_{16}$ and $\operatorname{tr} A = 0$ (Section 10.28). For $m = 2$: $AA = (4-9)I_{16} = -5I_{16}$, eigenvalues $\pm i\sqrt{5}$ (eight each), growth rate $\sqrt{5} \approx 2.236$: these finite-norm waves grow. For $m = 4$: $AA = 7I_{16}$, eigenvalues $\pm\sqrt{7} \approx \pm 2.646$, real: the waves oscillate (Figure 4 of Notebook 10d: zero growth rate for $m \geq 3H$).

11 GKD and the Lovelock tensors

Einstein's equations of gravity set one curvature tensor, the Einstein tensor, equal to the energy and momentum of matter. In eight dimensions there is room for more: two further tensors, built from products of two and of three curvature tensors, have the same good properties as Einstein's. Together with Einstein's they are the three **Lovelock tensors** of the formula (4.38) that the author quotes in his notebook. Every term of these tensors carries a weight $+1$, -1 or 0 given by the **generalized Kronecker delta**, which the author defined as a determinant and which the Revision program computes with a fast rule called **GKD**. This chapter proves that the rule is right, counts and tests it, builds the three Lovelock tensors of the author's metric twice (with the Revision Rust program and with independent Python code), proves their classical identities, and studies their components along the history in which the three extra times deflate exponentially. Chapter 12 then turns these components into the field equations for a_4.

11.1 What this chapter does, and why

In Chapter 3 we computed the curvature of the author's metric: its Christoffel symbols, its Riemann tensor $R^{ab}{}_{cd}$, its Ricci tensor and its Einstein tensor $G^h{}_j$. Einstein's field equations, $G^\mu{}_\nu + \Lambda\delta^\mu{}_\nu = \kappa T^\mu{}_\nu$, use only the Einstein tensor. Why that tensor? Because its **divergence** vanishes for every metric (the contracted Bianchi identity, Section 3.25), as the conservation of energy and momentum demands of the right-hand side. In 1971 David Lovelock found every tensor with this property that is built from the metric and its first and second derivatives (D. Lovelock, J. Math. Phys. 12, 498 (1971); we quote his theorem and do not prove it). In four dimensions only the Einstein tensor (and the constant term Λ) exists. In eight dimensions there are exactly three: the Einstein tensor and two companions. The author's notebook quotes them in the form of equation (4.38) of the book of Lovelock and Rund, and the Revision computed them for the author's metric (folder `Revision/gkd_lovelock`).

The chapter has three parts, each with one notebook.

- **The generalized Kronecker delta** (Sections 11.3 to 11.9). We restate the author's definition, a determinant of a matrix of zeros and ones, prove that it equals the sign of a permutation or zero, and show that this rule (GKD) is exactly what the Revision's Rust program computes. We count how often each value occurs, prove that a delta with nine labels in eight dimensions is always zero, compare the cost of the rule with the cost of the determinant, and connect the delta with the Levi-Civita tensors of the curved metric (the author's second route). Notebook 11a checks all of this in Python and runs the Rust self-test.
- **The three Lovelock tensors** (Sections 11.10 to 11.19). We recall the curvature of the author's metric, define the Lovelock tensors $P_{(1)}, P_{(2)}, P_{(3)}$ and the Lovelock scalars $L_{(1)}, L_{(2)}, L_{(3)}$,

explain how the enormous sums are organised so that a computer can do them exactly, and prove by hand, line by line, that $P_{(1)} = -4G$, that $P_{(2)} = -8$ times the Gauss-Bonnet tensor, and the trace identity. Notebook 11b runs the Rust program `lovelock_gkd`, checks that it reproduces the Revision records byte for byte, and computes everything a second time in Python.

- **The components along the deflating history** (Sections 11.20 to 11.27). We write out the components of the normalised tensors $E_{(k)} = -P_{(k)}/2^{k+1}$, prove their structure (which components are equal, which contain a_4'', which do not care about the sign of a_4'), derive the two conservation identities that they obey, and draw them along the exponentially deflating history $a_4 = AHx_4$ and along an illustrative test history. Notebook 11c does this with exact algebra.

Everything in this chapter is geometry of the given metric: no physical assumption about matter enters, and nothing here concerns pairs of universes or matter and antimatter. Every formula is PROVED (by a derivation written out here, or by exact computation in the Revision records and the notebooks) or COMPUTED (a numerical test), and each statement names the record file and check that confirm it.

11.2 The words and symbols of this chapter

Each word is defined in plain terms here; the later sections make the definitions precise.

- **Coordinates** $x_0, \ldots, x_7$: the author's names of the eight directions. x_1, x_2, x_3: ordinary 3-space (they inflate). x_4: the time. x_5, x_6, x_7: the three **extra times**, time-like directions that **deflate exponentially** when a_4 grows. x_0: the hidden space direction, through the angle $z = 6Hx_0$ with $0 < z < \pi/2$. Programs number the coordinates $0, 1, \ldots, 7$, so the number 3 stands for x_4 and the number 7 for x_0.

- **Label**: the name of a coordinate. **Index list**: an ordered list of labels, such as (x_2, x_1, x_4); its **length** p is the number of entries. A **pair** of index lists is a **lower** list $(l_1, \ldots, l_p)$ and an **upper** list $(u_1, \ldots, u_p)$ of the same length.

- **Kronecker delta** $\delta(a, b) = \delta^b_a$: the number 1 if the labels a and b are equal, 0 otherwise.

- **Permutation**, **inversion**, **sign**: a permutation is a re-ordering of p objects, written as the list $(\sigma(1), \ldots, \sigma(p))$; an inversion is a pair of places $i < j$ with $\sigma(i) > \sigma(j)$; the sign is $(-1)^{\text{number of inversions}}$, $+1$ for an **even** and -1 for an **odd** permutation (Section 1.19).

- **Determinant** (Leibniz formula): $\det M = \sum_\pi \operatorname{sign}(\pi)\, M_{1\pi(1)} \cdots M_{p\pi(p)}$, a sum of $p!$ products, one for every permutation π (Section 1.20). **Minor** $M^{(rc)}$: the matrix left when row r and column c of M are removed.

- **Generalized Kronecker delta**: $\delta^{u_1 \ldots u_p}_{l_1 \ldots l_p} = \det[\delta(l_i, u_j)]$, the author's `kδ[lower, upper]`. **GKD**: the Rust function of the Revision program that computes it by the rule proved in Section 11.3.

- **Pigeonhole principle**: if more than n objects are put into n boxes, some box holds two of them.

- **Levi-Civita symbol** $[i_1 \dots i_n]$: the sign of the list $(i_1, \dots, i_n)$ if it is a re-ordering of all n labels, and 0 otherwise (Section 1.44).
- **Metric** g_{ab}, **inverse metric** g^{ab}: the author's metric is diagonal, so $g^{aa} = 1/g_{aa}$ and all other entries are zero.
- **Christoffel symbol** $\Gamma^a{}_{bc}$, **Riemann tensor** $R^a{}_{bcd}$ and $R^{ab}{}_{cd} = g^{bb} R^a{}_{bcd}$, **plane curvature** $K(a,b) = R^{ab}{}_{ab}$ (no sum), **Ricci tensor** $R^h{}_j = \sum_c R^{hc}{}_{jc}$, **Ricci scalar** $R = \sum_h R^h{}_h$, **Einstein tensor** $G^h{}_j = R^h{}_j - \frac{1}{2}\delta^h_j R$: Chapter 3 (Sections 3.15 and 3.17) defines them.
- **Summed label**: in this chapter a label that appears once up and once down inside one term is summed over its eight values, unless "no sum" is said; the free labels h and j are never summed.
- **Lovelock tensor** $P_{(k)}{}^h{}_j$ of **order** k and **Lovelock scalar** $L_{(k)}$: the sums of Section 11.11. **Normalised Lovelock tensor** $E_{(k)} = -P_{(k)}/2^{k+1}$; $E_{(1)}$ is the Einstein tensor. **Gauss-Bonnet tensor**: the classical name of the order-2 Lovelock tensor. **Density** $A_{(k)}{}^{lh} = \sqrt{|\det g|}\, g^{ll} P_{(k)}{}^h{}_l$: the form in which formula (4.38) is written.
- **Euler density**: in a space of even dimension $n = 2m$, the Lovelock scalar of order m (in eight dimensions $L_{(4)}$). For a closed space (finite, without an edge) with a positive-definite metric its integral is a constant times the **Euler characteristic**, a whole number fixed by the shape of the space that does not change when the metric is deformed (Section 11.11; a classical theorem, quoted: ASSUMED).
- **Component**: one number of a tensor, such as $E^{x_1}{}_{x_1}$; a **diagonal** component has $h = j$.
- **Leaf**, **pruning** (skipping): a complete combination of k curvature entries in the computer's search; pruning means leaving out combinations known to give zero.
- **Divergence** $\nabla_h P^h{}_j$: the curved-space form of "change plus outflow"; zero divergence means **conservation**.
- **History** $a_4(x_4)$: the metric function. **Linear history**: $a_4 = AHx_4$ with a constant **slope** A, so $a_4' = AH$ and $a_4'' = 0$; for $A > 0$ the extra times shrink like e^{-AHx_4}. **Illustration**: a choice made only to show how a formula behaves; it is not a solution of any equation.
- **Exact** computation: with whole numbers and fractions, no rounding. **Byte for byte**: two files equal in every byte.
- **Status labels**: PROVED (exact, by a derivation or by exact computation, with the record file and check), COMPUTED (numerical, with its accuracy), ASSUMED, HYPOTHESIS, OPEN.
- **The record files of this chapter.** Where a record file is named without its folder, it lies in the folder `Revision/gkd_lovelock/results`: `lovelock-report.json` (the report of the Rust program, with its 19 checks and its counters), `curvature.json` (the metric, the Christoffel symbols, the Riemann, Ricci and Einstein tensors), `lovelock-tensors.json` (every component of the Lovelock tensors and the scalars), `gkd-selftest.json` (the GKD self-test), `python-lovelock-report.json` (the Revision's independent sympy verification) and `wolfram-gkd-report.json` (the Revision's independent Wolfram verification). The record of the field equations of a_4 is `Revision/field_equations_a4/a4-equations.json`, with its sympy report `Revision/field_equations_a4/reports/python-a4-report.json`.

11.3 The author's generalized Kronecker delta and the rule GKD

The definition. The author defined the generalized delta in an input cell of his Mathematica notebook. The Revision record quotes the cell verbatim in `Revision/gkd_lovelock/results/PROVENANCE_OF_THE_COMPUTATION.md` (the cell stored as In[87], the author's In[54]); in Mathematica's plain-text spelling it reads

```
k\[Delta][lower_, upper_] /; Length[lower] == Length[upper] :=
    Det[Outer[delta, lower, upper]]
```

For a lower list $(l_1, \ldots, l_p)$ and an upper list $(u_1, \ldots, u_p)$ of the same length (the condition after `/;`), `Outer[delta, lower, upper]` is the $p \times p$ matrix M with the entry $M_{ij} = \delta(l_i, u_j)$ in row i and column j: one row for each lower label, one column for each upper label, and a 1 wherever the two labels are equal. `Det` takes its determinant. So

$$\delta^{u_1 \ldots u_p}_{l_1 \ldots l_p} = \det\left[\delta(l_i, u_j)\right]_{i,j=1,\ldots,p}.$$

For two lists of different lengths the definition does not apply, and Mathematica leaves the expression unevaluated (record `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, check `definition_unequal_lengths_stay_unevaluated`). For $p = 1$ the matrix is the single number $\delta(l_1, u_1)$, so the generalized delta of one label is the ordinary Kronecker delta. For $p = 2$:

$$\delta^{u_1 u_2}_{l_1 l_2} = \det \begin{pmatrix} \delta(l_1, u_1) & \delta(l_1, u_2) \\ \delta(l_2, u_1) & \delta(l_2, u_2) \end{pmatrix}$$

(the definition with $p = 2$),

$$= \delta(l_1, u_1)\, \delta(l_2, u_2) - \delta(l_1, u_2)\, \delta(l_2, u_1)$$

(the 2×2 determinant is $ad - bc$, Section 1.20). For example $\delta^{x_1 x_2}_{x_1 x_2} = 1 \cdot 1 - 0 \cdot 0 = 1$ and $\delta^{x_2 x_1}_{x_1 x_2} = 0 \cdot 0 - 1 \cdot 1 = -1$.

Theorem (the rule GKD; PROVED). Let $M_{ij} = \delta(l_i, u_j)$. Then $\det M = 0$ if a label appears twice in the lower list, or twice in the upper list, or if some lower label does not appear in the upper list. Otherwise $\det M = \mathrm{sign}(\sigma)$, where $\sigma(i)$ is the place of l_i in the upper list.

Proof, case by case.

(a) Two equal lower labels, $l_i = l_k$ with $i \neq k$. For every column j,

$$M_{ij} = \delta(l_i, u_j) = \delta(l_k, u_j) = M_{kj}$$

(the definition of M; then $l_i = l_k$; then the definition again). So rows i and k are equal, and a matrix with two equal rows has determinant 0 (rule 4 of Section 1.20: exchanging the two rows changes nothing, yet flips the sign, so $\det M = -\det M$ and $\det M = 0$).

(b) Two equal upper labels, $u_j = u_k$ with $j \neq k$. By the same steps columns j and k are equal, so the transpose M^T has two equal rows and $\det M = \det M^T = 0$ (rules 2 and 4 of Section 1.20).

(c) A lower label l_i that equals no upper label. Then $M_{ij} = 0$ for every j: row i is all zeros. Every product of the Leibniz formula contains exactly one entry of row i, so every product is 0, and $\det M = 0$.

(d) Otherwise: the p lower labels are different, the p upper labels are different, and every lower label appears among the upper labels. Then l_i equals exactly one upper label, the one at the place $\sigma(i)$. Different lower labels sit at different places of the upper list, so σ sends the places $1, \ldots, p$ to the places $1, \ldots, p$ without repetition: σ is a permutation. Row i of M has its only 1 in column $\sigma(i)$, so M is the permutation matrix of σ. In the Leibniz formula the product of a permutation π is $M_{1\pi(1)} \cdots M_{p\pi(p)}$; it is 1 when $\pi(i) = \sigma(i)$ for every i and 0 otherwise (one factor is then an entry off the 1s). Only the term $\pi = \sigma$ survives:

$$\det M = \operatorname{sign}(\sigma) \cdot 1 \cdots 1 = \operatorname{sign}(\sigma).$$

End of proof. □

The same theorem is proved in Section 1.42; it is repeated here because the whole chapter rests on it. It is also written, as the opening comment, in the Rust file `Revision/gkd_lovelock/code/src/gkd.rs`.

The rule as a recipe. The Rust function `GKD(lower, upper)` follows the proof step by step, without building a matrix:

- It walks through the upper list and notes the place of every label. A label seen a second time means two equal columns: it returns 0 (case b).
- It walks through the lower list and looks up the place of every label. A label not found means a row of zeros: it returns 0 (case c). A place found a second time means two equal lower labels: it returns 0 (case a). The places form the list σ.
- It counts the inversions of σ and returns $+1$ for an even count and -1 for an odd count (case d).

Counting the inversions of a list of p entries compares each of the $p(p-1)/2$ pairs of places once. The Leibniz formula instead adds $p!$ products. For $p = 7$, the length that the third Lovelock tensor needs, this is 21 comparisons against 5,040 products.

Examples (PROVED). Take the lower list (x_1, x_2, x_3, x_4).

- Upper list (x_2, x_1, x_4, x_3): the places of x_1, x_2, x_3, x_4 in it are $\sigma = (2, 1, 4, 3)$ (counting from 1). The inversions are the pairs of entries $(2, 1)$ and $(4, 3)$: two, an even number, so the value is $+1$.
- Upper list (x_2, x_3, x_4, x_1): $\sigma = (4, 1, 2, 3)$; the inversions are $(4, 1)$, $(4, 2)$, $(4, 3)$: three, odd, value -1.
- Lower list (x_1, x_2, x_3, x_3) with upper list (x_1, x_2, x_3, x_4): x_3 repeats in the lower list, case (a), value 0.

These are the three matrices of Figure 11a.1 (Notebook 11a, In [3]). The Revision record lists five examples with the labels 1 to 4, lower list first: `kdelta[{1,2},{1,2}] = 1`, `kdelta[{1,2},{2,1}] = -1`, `kdelta[{1,1},{1,1}] = 0`, `kdelta[{1,2,3},{2,3,1}] = 1`, `kdelta[{1,2,3},{1,2,4}] = 0` (`Revision/gkd_lovelock/results/python-lovelock-report.json`, check `gkd_examples`). Any whole numbers can serve as labels, because only the equality of two labels matters. Notebook 11a, In [2] and In [4], reproduces all five with both the determinant and the rule.

11.4 Counting the values; nine labels in eight dimensions; the cost of the determinant

The number of nonzero values (PROVED). Fix the length $p \le 8$. By the theorem, a pair has a nonzero value exactly when the lower list holds p different labels and the upper list holds the same p labels in some order. The lower list can be chosen in

$$8 \cdot 7 \cdots (8-p+1) = \frac{8!}{(8-p)!}$$

ways (8 choices for the first label, 7 for the second, which must differ from the first, and so on; the numbers of choices multiply). For each such lower list the upper list can be any of its $p!$ orders. So the number of pairs with a nonzero value is

$$N_{\neq 0}(p) = \frac{8!}{(8-p)!}\, p!$$

out of $8^p \cdot 8^p = 8^{2p}$ pairs (8 choices for each of the $2p$ entries).

Half are $+1$, half are -1 (PROVED, for $p \ge 2$). Exchange the first two labels of the upper list. In σ this exchanges the values 1 and 2 (the places of these two labels). The two entries of σ that hold the values 1 and 2 change their relative order, so the pair they form becomes an inversion if it was none, and stops being one if it was one. Every other pair of entries is compared as before: a pair that contains neither of the two entries is unchanged, and an entry with a value of 3 or more is larger than both 1 and 2, so its comparison with either of them gives the same answer. Hence the number of inversions changes by exactly one, and the exchange turns every even order into an odd one. Doing it twice gives back the original order, so the exchange pairs the even orders with the odd orders one to one: there are as many of each. For $p = 1$ the only order is the identity, which is even. (Section 1.19 proves the same for every exchange of two entries.)

The table (PROVED by the formula; COMPUTED by counting). With $8!/(8-p)!$ equal to 8, 56, 336, 1680 for $p = 1, 2, 3, 4$:

length p	**all pairs** 8^{2p}	**value** $+1$	**value** -1	**value 0**
1	64	8	0	56
2	4096	56	56	3984
3	262144	1008	1008	260128
4	16777216	20160	20160	16736896

For example $p = 3$: $336 \cdot 3! = 336 \cdot 6 = 2016$ nonzero values, half of them, 1008, of each sign, and $262144 - 2016 = 260128$ zeros. The counts for $p = 1, 2, 3$ are those of the Revision's

Wolfram verification, which called the author's verbatim definition on every one of these 266,304 pairs (`Revision/gkd_lovelock/results/wolfram-gkd-report.json`, field `measurements`, entry `gkdComparison`, and checks `gkd_equals_kdelta_exhaustive_length_1` to `_length_3`); Notebook 11a counts them again (In [6]) and compares them with the formula and with the record (In [7]). The row $p = 4$ comes from the formula; the Rust self-test of the record compared all 16,777,216 pairs of length 4 (`Revision/gkd_lovelock/results/gkd-selftest.json`), and Notebook 11a runs it again (In [14]). Figure 11a.4 draws the table.

Nine labels in eight dimensions (PROVED). A list of 9 labels taken from only 8 must repeat a label, by the pigeonhole principle. So case (a) applies, and every generalized delta with $p \geq 9$ is zero. The Lovelock tensor of order k (Section 11.11) carries a delta of length $p = 2k + 1$: $p = 3, 5, 7$ for $k = 1, 2, 3$, and $p = 9$ for $k = 4$. Therefore the Lovelock tensor of order 4, and every higher one, vanishes identically in eight dimensions, and the Lovelock sum stops at $k = 3$ (record `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `gkd_nine_indices_in_eight_dimensions_vanish`; record `Revision/gkd_lovelock/results/lovelock-report.json`, check `k4_tensor_vanishes`; Notebook 11a, In [10]).

The cost of the determinant (PROVED by counting). The Leibniz formula of a $p \times p$ determinant adds $p!$ products; the rule GKD makes $p(p-1)/2$ comparisons of places. And the number 8^{2p} of all pairs grows so fast that only the lengths up to 4 can be tested exhaustively:

length p	**products** $p!$	**comparisons** $p(p-1)/2$	**all pairs** 8^{2p}
1	1	0	64
2	2	1	4096
3	6	3	2.6×10^5
4	24	6	1.7×10^7
5	120	10	1.1×10^9
6	720	15	6.9×10^{10}
7	5040	21	4.4×10^{12}
8	40320	28	2.8×10^{14}
9	362880	36	1.8×10^{16}

(Notebook 11a, In [12], prints this table and draws it as Figure 11a.5.) The work of one literal determinant grows by the factor p from one length to the next, because $p! = p \cdot (p-1)!$. Notebook 11a also measures both methods on the same 200 pairs of length 7 and checks that the rule is more than ten times faster (In [12]). It does not print the measured times: they differ from computer to computer and from run to run, and the printed output of every notebook of this book must be the same on every run.

Random tests and the birthday problem (PROVED; COMPUTED). For the lengths 5 to 9 the Rust self-test of the record compares GKD with the literal determinant on 200,000 pseudo-random pairs of each length (Section 1.49 explains the generator `xorshift64*` and its seeds). Half of the samples are **rearranged** pairs: p random labels form the upper list and the lower list is the same list in a random order. The other half are two **independent** random lists. A rearranged pair has a nonzero value exactly when its p random labels are all different. Each label is one of 8 with equal chance, so this happens with the probability

$$r_p = \frac{8}{8}\cdot\frac{7}{8}\cdots\frac{8-p+1}{8} = \frac{8!}{(8-p)!\,8^p}$$

(the first label may be anything; the second must avoid the first, 7 of 8 values; the third must avoid the first two, 6 of 8; and so on; independent chances multiply, a rule of probability ASSUMED here, Section 1.50). This is the **birthday problem** with 8 possible birthdays. An independent pair is nonzero with the small probability $q_p = N_{\neq 0}(p)/8^{2p}$. With N samples of each kind the expected number of nonzero values is $N(r_p + q_p)$, and the usual random scatter of such a count, its **standard deviation**, is $\sqrt{Nr_p(1-r_p) + Nq_p(1-q_p)}$ (ASSUMED from probability theory). For $p = 5$ and $N = 100000$:

$$r_5 = \frac{8\cdot 7\cdot 6\cdot 5\cdot 4}{8^5} = \frac{6720}{32768} = 0.20508, \qquad q_5 = \frac{6720\cdot 120}{8^{10}} = \frac{806400}{1073741824} = 0.00075$$

(the formula; then $8^5 = 32768$ and $8^{10} = 1073741824$), so the expected count is $100000\cdot(0.20508 + 0.00075) = 20583$ (rounded), with a standard deviation of about 128. The record's count is 20538 (`gkd-selftest.json`), 0.35 standard deviations below the expectation. Notebook 11a, In [15], makes this comparison for every length 5 to 9 of the record, and In [11] for its own 2,000 Python samples of each length 4 to 9; all counts lie within 2 standard deviations (Figure 11a.6). For $p = 9$ the chance is $r_9 = 0$, because the factor $(8 - 9 + 1)/8 = 0$ appears: the pigeonhole principle once more, and both tests find no nonzero value. A random test is evidence, not a proof; the proof that GKD equals the determinant is the theorem of Section 11.3. The tests show that the two programs implement the theorem without a slip.

11.5 The author's second route: two Levi-Civita tensors of the curved metric

The author's notebook builds the generalized delta also in a second way, from two **Levi-Civita tensors**, in the cell In[32] (record `Revision/gkd_lovelock/results/notebook-input-cells.txt`). Section 1.44 proved the identity behind it for the Levi-Civita **symbol** $[i_1 \ldots i_8]$ (the sign of the list, or 0):

$$\sum_{c_2,\ldots,c_8} [a\, c_2 \ldots c_8]\,[b\, c_2 \ldots c_8] = 7!\;\delta^b_a.$$

The author uses the Levi-Civita **tensor** of a curved metric g, whose second factor carries upper labels raised with the inverse metric. Section 1.44 used the fact that raising all labels multiplies the product by the sign of $\det g$, and promised it here. We prove it now.

A determinant identity (PROVED). For every $n \times n$ matrix N and every list $(i_1, \ldots, i_n)$,

$$\sum_{m_1,\ldots,m_n} N_{i_1 m_1}\cdots N_{i_n m_n}\,[m_1 \ldots m_n] = \det N\;[i_1 \ldots i_n].$$

Proof. (i) For the list $(i_1, \ldots, i_n) = (1, \ldots, n)$: the symbol $[m_1 \ldots m_n]$ is 0 unless $(m_1, \ldots, m_n)$ is a permutation π, and then it is $\mathrm{sign}(\pi)$; so the left side is $\sum_\pi \mathrm{sign}(\pi) N_{1\pi(1)}\cdots N_{n\pi(n)}$, the Leibniz formula, which is $\det N = \det N\,[1 \ldots n]$. (ii) Exchanging two entries of the list $(i_1, \ldots, i_n)$ exchanges

two rows of the products on the left, which flips the sign of the left side (rule 3 of Section 1.20, applied to the matrix with the rows $i_1, \dots, i_n$), and it flips the sign of $[i_1 \dots i_n]$ on the right (Section 1.19). Every re-ordering of $(1, \dots, n)$ is reached by such exchanges, so both sides agree for every re-ordering. (iii) If the list repeats a label, the matrix with the rows $i_1, \dots, i_n$ has two equal rows, so the left side is 0 (rule 4), and so is the right side. □

Raising all labels (PROVED). The Levi-Civita tensor of g is $\varepsilon_{i_1 \dots i_8} = \sqrt{|\det g|}\,[i_1 \dots i_8]$; raising all its labels gives

$$\varepsilon^{i_1 \dots i_8} = \sum_{m_1, \dots, m_8} g^{i_1 m_1} \cdots g^{i_8 m_8} \sqrt{|\det g|}\,[m_1 \dots m_8]$$

(one inverse metric for each label),

$$= \sqrt{|\det g|}\ \det(g^{-1})\,[i_1 \dots i_8] = \frac{\sqrt{|\det g|}}{\det g}\,[i_1 \dots i_8]$$

(the identity just proved with $N = g^{-1}$; then $\det(g^{-1}) = 1/\det g$, rule 1 of Section 1.20 applied to $g\,g^{-1} = I$). For the author's diagonal metric no general rule is needed: only $m_r = i_r$ survives in each sum, and the product $g^{i_1 i_1} \cdots g^{i_8 i_8}$ over a re-ordering of all eight labels is the product of all eight diagonal entries $1/g_{aa}$, which is $1/\det g$ (the determinant of a diagonal matrix is the product of its diagonal, Section 1.20). Multiplying the two tensors,

$$\varepsilon_{a_1 \dots a_8}\,\varepsilon^{b_1 \dots b_8} = \sqrt{|\det g|} \cdot \frac{\sqrt{|\det g|}}{\det g}\,[a_1 \dots a_8][b_1 \dots b_8] = \frac{|\det g|}{\det g}\,[a_1 \dots a_8][b_1 \dots b_8]$$

(the two definitions; $\sqrt{u}\sqrt{u} = u$), and $|\det g|/\det g$ is the sign of $\det g$. For the author's metric $\det g = \cos^2 z > 0$ for every a_4 (with the second function b_4 of the metric of 2026-10-14, $\det g = b_4^3 \cos^2 z$, still positive) (record `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `sqrt_abs_det_g`; `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, check `sqrt_det_g_is_cos`; Section 1.21), so the sign is $+1$: the product of the two curved Levi-Civita tensors is exactly the product of the two symbols, and the author's second route gives, after the contraction over seven labels and the division by 7!, the ordinary Kronecker delta δ^b_a with no extra sign. In a metric with an odd number of time-like directions, such as the four-dimensional spacetime of everyday physics, the sign would be -1. Notebook 01c checks the author's second route with the flat metric of signature (4,4) (Section 1.44).

11.6 Example: the generalized Kronecker delta in Python and in Rust

Notebook 11a puts Sections 11.3 and 11.4 to work. It writes the author's definition literally in Python, as an exact determinant computed by sympy; writes the rule GKD as a Python function; reproduces the record's five examples; draws three 4×4 matrices and all six arrangements of three labels; compares the rule with the determinant for all 266,304 pairs of lengths 1 to 3 and for 12,000 pseudo-random pairs of lengths 4 to 9; counts the values and compares the counts with the formula and with the Wolfram record; shows that every delta of nine labels vanishes; compares the cost of the two methods; builds the Revision Rust program `lovelock_gkd` with cargo and reads the record `Revision/gkd_lovelock/results/gkd-selftest.json` of its GKD self-test, checking every

row; compares the self-test's counts with the birthday formula; and checks once more that every check and number it quotes from the Revision records is there. It needs Rust. The Rust self-test itself takes 7 to 13 minutes, because it computes 200,000 literal determinants of 9×9 matrices, each a sum of 362,880 products; that is longer than the limit of 7 minutes that this book sets for one computation, so the notebook prints the command that repeats it instead of running it (In [13]). The whole notebook took 8.2 seconds when it was built on 2026-10-15 (the provenance file `Revision/textbook/notebooks/11a_kronecker_delta_gkd.PROVENANCE.md`). It prints 24 PASS lines, draws six figures and ends with the line ALL 24 CHECKS PASSED (notebook 11a).

11.7 How to run Notebook 11a

Step 1. What this notebook does and what it needs.

Notebook 11a (The generalized Kronecker delta GKD in Python and in Rust) is the file `Revision /textbook/notebooks/11a_kronecker_delta_gkd.ipynb` of the repository Dirac_claude. It writes the author's generalized Kronecker delta literally as the determinant of a matrix of zeros and ones, proves and checks that it equals the sign of a permutation or zero (the rule of the Rust function GKD), compares the two for all 266,304 pairs of index lists of length 1, 2 and 3 over the eight coordinate labels and for 12,000 random pairs of length 4 to 9, counts how often the values +1, -1 and 0 occur and derives these counts by a formula, shows why the delta of nine indices in eight dimensions is always zero, and builds the Revision Rust program lovelock_gkd with cargo inside the notebook when the program file is missing (a few seconds, up to a minute on a slow computer; about a second when it is up to date), reads the record of its GKD self-test (16,777,216 pairs of length 4 compared exhaustively, 200,000 random pairs of each length 5 to 9) and checks every row of it; the self-test itself takes 7 to 13 minutes, longer than the limit of 7 minutes set for one computation, so the notebook does not run it and prints the command that repeats it; it checks again that every check and number it quotes from the Revision records is there, with the verdict PASS; it draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the Rust program lovelock_gkd, which is part of the repository and is built on your computer.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download `rustup-init.exe` from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run `rustup-init.exe` again). macOS and Linux: run the command below and accept the default choice (on Linux first run `sudo apt install build-essential`, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file `Revision/gkd_lovelock/code/target/release/lovelock_gkd` (on Windows with the ending `.exe`). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 11a_kronecker_delta_gkd.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows

a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 11a_kronecker_delta_gkd.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 11a_kronecker_delta_gkd.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/11a.captions.json`
- `Revision/textbook/figures/11a_1_outer_delta_matrices.png`
- `Revision/textbook/figures/11a_2_six_permutations.png`
- `Revision/textbook/figures/11a_3_gkd_map_length_two.png`
- `Revision/textbook/figures/11a_4_value_counts.png`
- `Revision/textbook/figures/11a_5_cost_of_the_determinant.png`
- `Revision/textbook/figures/11a_6_all_labels_different.png`

It changes no other file of the repository except the Rust build folder `target` next to each `Cargo.toml` it builds; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files of the notebook exist
ALL 24 CHECKS PASSED (notebook 11a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 11a_kronecker_delta_gkd.ipynb
python -m nbconvert --execute --inplace 11a_kronecker_delta_gkd.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this terminal.
- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build again.
- AssertionError: check failed: the record of the Rust program lovelock_gkd gkd-selftest has the verdict SUCCESS: The committed record differs from the one this notebook was written for. Run git status in the repository folder to see whether the record was changed, and restore it with the command below.

```
git checkout -- Revision/gkd_lovelock/results/gkd-selftest.json
```

11.8 Notebook 11a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The Lovelock tensors of chapter 11 are long sums of products of the curvature of the
author's metric. Every term of these sums carries a weight that is the value of the
**generalized Kronecker delta**, a number $+1$, $-1$ or $0$ that depends on two lists
of coordinate labels. The author defined it, in his Mathematica notebook, as the
determinant of a matrix of zeros and ones. The Revision Rust program `lovelock_gkd`
computes it with a faster rule, the function **GKD**. This notebook

- writes the author's definition literally in Python (a determinant computed exactly
  by sympy) and evaluates it on examples;
- proves that the determinant is always the sign of a permutation or zero, writes
  this rule (GKD) in Python, and checks that the two agree on all 266,304 pairs of
  index lists of length 1, 2 and 3 over the eight labels $x_0, \dots, x_7$, and on
  12,000 pseudo-random pairs of length 4 to 9;
- counts how often the values $+1$, $-1$ and $0$ occur, derives the counts with a
  formula, and reproduces the counts recorded by the Revision's Wolfram check;
- shows that a delta with nine or more indices is always zero in eight dimensions
  (the pigeonhole principle), which is why the Lovelock sum stops at order 3;
- measures that the rule is much faster than the determinant and draws the cost of
  both;
- builds the Revision Rust program `lovelock_gkd` with cargo and reads the record
  `Revision/gkd_lovelock/results/gkd-selftest.json` of its GKD self-test, which
  compares GKD with the literal determinant on 16,777,216 pairs of length 4 and on
  200,000 random pairs of each length 5 to 9; the self-test itself takes 7 to 13
  minutes, longer than the limit of 7 minutes for one computation of this book, so
  the notebook prints the command that repeats it instead of running it;
```

- reads the Revision records once more and checks that every check and number it
  quotes from them is there, every quoted check with the verdict PASS.

It draws six figures and takes about a minute.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 11a (The generalized Kronecker delta GKD in Python and in Rust) is the file
‘Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb‘ of the repository
Dirac_claude. It writes the author’s generalized Kronecker delta literally as the
determinant of a matrix of zeros and ones, proves and checks that it equals the sign of a
permutation or zero (the rule of the Rust function GKD), compares the two for all 266,304
pairs of index lists of length 1, 2 and 3 over the eight coordinate labels and for 12,000
random pairs of length 4 to 9, counts how often the values +1, -1 and 0 occur and derives
these counts by a formula, shows why the delta of nine indices in eight dimensions is
always zero, and builds the Revision Rust program lovelock_gkd with cargo inside the
notebook when the program file is missing (a few seconds, up to a minute on a slow
computer; about a second when it is up to date), reads the record of its GKD self-test
(16,777,216 pairs of length 4 compared exhaustively, 200,000 random pairs of each length
5 to 9) and checks every row of it; the self-test itself takes 7 to 13 minutes, longer
than the limit of 7 minutes set for one computation, so the notebook does not run it and
prints the command that repeats it; it checks again that every check and number it quotes
from the Revision records is there, with the verdict PASS; it draws six teaching figures.
It needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the Rust
program lovelock_gkd, which is part of the repository and is built on your computer.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):
```

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
```

```
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download ‘rustup-init.exe‘ from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run ‘rustup-init.exe‘

again). macOS and Linux: run the command below and accept the default choice (on Linux first run ‘sudo apt install build-essential‘, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file ‘Revision/gkd_lovelock/code/target/release/lovelock_gkd‘ (on Windows with the ending ‘.exe‘). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 11a_kronecker_delta_gkd.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 11a_kronecker_delta_gkd.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 11a_kronecker_delta_gkd.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/11a.captions.json‘
- ‘Revision/textbook/figures/11a_1_outer_delta_matrices.png‘
- ‘Revision/textbook/figures/11a_2_six_permutations.png‘
- ‘Revision/textbook/figures/11a_3_gkd_map_length_two.png‘
- ‘Revision/textbook/figures/11a_4_value_counts.png‘
- ‘Revision/textbook/figures/11a_5_cost_of_the_determinant.png‘
- ‘Revision/textbook/figures/11a_6_all_labels_different.png‘

It changes no other file of the repository except the Rust build folder ‘target‘ next to each ‘Cargo.toml‘ it builds; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS all six figure files of the notebook exist
    ALL 24 CHECKS PASSED (notebook 11a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from

  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb‘ inside the folder
  Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 11a_kronecker_delta_gkd.ipynb
      python -m nbconvert --execute --inplace 11a_kronecker_delta_gkd.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open
  a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this
  terminal.
- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++
  Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build
  again.
- AssertionError: check failed: the record of the Rust program lovelock_gkd gkd-selftest
  has the verdict SUCCESS: The committed record differs from the one this notebook was
  written for. Run git status in the repository folder to see whether the record was
  changed, and restore it with the command below.

      git checkout -- Revision/gkd_lovelock/results/gkd-selftest.json

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 11a (the complete instructions)
#
```

```
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 11a (The generalized Kronecker delta GKD in Python and in Rust) is the file
# Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb of the repository
# Dirac_claude. It writes the author's generalized Kronecker delta literally as the
# determinant of a matrix of zeros and ones, proves and checks that it equals the sign of
# a permutation or zero (the rule of the Rust function GKD), compares the two for all
# 266,304 pairs of index lists of length 1, 2 and 3 over the eight coordinate labels and
# for 12,000 random pairs of length 4 to 9, counts how often the values +1, -1 and 0
# occur and derives these counts by a formula, shows why the delta of nine indices in
# eight dimensions is always zero, and builds the Revision Rust program lovelock_gkd with
# cargo inside the notebook when the program file is missing (a few seconds, up to a
# minute on a slow computer; about a second when it is up to date), reads the record of
# its GKD self-test (16,777,216 pairs of length 4 compared exhaustively, 200,000 random
# pairs of each length 5 to 9) and checks every row of it; the self-test itself takes 7
# to 13 minutes, longer than the limit of 7 minutes set for one computation, so the
# notebook does not run it and prints the command that repeats it; it checks again that
# every check and number it quotes from the Revision records is there, with the verdict
# PASS; it draws six teaching figures. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It also needs Rust (the program cargo,
# version 1.91.1 or newer), because it runs the Rust program lovelock_gkd, which is part
# of the repository and is built on your computer.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
```

```
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):

#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. INSTALL RUST AND BUILD THE RUST PROGRAM (RUST ONCE PER COMPUTER, THE BUILD ONCE
# PER PROGRAM).
#
# Windows: download rustup-init.exe from https://rustup.rs, run it and accept the default
# choices; if it reports that the Visual Studio C++ Build Tools are missing, let it
# install them (or install the workload "Desktop development with C++" from
# https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run rustup-init.exe
# again). macOS and Linux: run the command below and accept the default choice (on Linux
# first run sudo apt install build-essential, which provides the linker that Rust needs).
#
# macOS (zsh) and Linux (bash):
#     curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
#
# Then close the terminal, open a new one, do Step 4 again, and check the version of
# cargo; it must print 1.91.1 or a newer version:
#
# Windows, macOS and Linux:
#     cargo --version
#
# Build the program with the following command, in the repository folder (the same
# command on all three systems):
#
# Windows, macOS and Linux:
#     cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
#
```

```
# The first build takes about 1 minute; later builds reuse the result and take a few
# seconds. The program is then the file
# Revision/gkd_lovelock/code/target/release/lovelock_gkd (on Windows with the ending
# .exe). The notebook runs the same build command itself before it uses the program (it
# takes a second when the program is up to date), so the notebook also works if you skip
# this build; building here first shows any problem with Rust before the notebook starts.
#
# STEP 6. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 11a_kronecker_delta_gkd.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 1 minute
# on a typical laptop. Scroll to the end and compare the last printed lines with the
# lines in the step "What the notebook writes and what you must see" below. To keep the
# results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the
# menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 7. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 11a_kronecker_delta_gkd.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 11a_kronecker_delta_gkd.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 8. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/11a.captions.json
# - Revision/textbook/figures/11a_1_outer_delta_matrices.png
# - Revision/textbook/figures/11a_2_six_permutations.png
# - Revision/textbook/figures/11a_3_gkd_map_length_two.png
# - Revision/textbook/figures/11a_4_value_counts.png
# - Revision/textbook/figures/11a_5_cost_of_the_determinant.png
# - Revision/textbook/figures/11a_6_all_labels_different.png
#
```

```
# It changes no other file of the repository except the Rust build folder target next to
# each Cargo.toml it builds; running it headless or saving it in JupyterLab also rewrites
# the notebook file itself. It does not use the internet while it runs. The files it
# writes are the same files that are stored in the repository (on another computer a
# figure may differ in a few bytes, which is harmless). To get the stored versions back,
# run this command in the repository folder (it also undoes every change you made
# yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files of the notebook exist
#     ALL 24 CHECKS PASSED (notebook 11a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 9. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/11a_kronecker_delta_gkd.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 11a_kronecker_delta_gkd.ipynb
#     python -m nbconvert --execute --inplace 11a_kronecker_delta_gkd.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
```

```
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "cargo is not recognized" or "command not found: cargo" or "cargo was not found":
#   open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from
#   this terminal.
# - "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the
#   C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build
#   again.
# - AssertionError: check failed: the record of the Rust program lovelock_gkd
#   gkd-selftest has the verdict SUCCESS: The committed record differs from the one this
#   notebook was written for. Run git status in the repository folder to see whether the
#   record was changed, and restore it with the command below.
#     git checkout -- Revision/gkd_lovelock/results/gkd-selftest.json
#

```
## 3. The words used in this notebook

- **Coordinate label**: the name of one of the eight coordinates $x_0, \dots, x_7$ of
  the author's metric ($x_1, x_2, x_3$ ordinary space, $x_4$ the time, $x_5, x_6,
  x_7$ the three extra times, which deflate exponentially, $x_0$ the hidden
  direction). Programs number them
  $0, 1, \dots, 7$: the number 0 stands for $x_1$, the number 7 for $x_0$.
- **Index list**: a list of labels such as $(x_2, x_1, x_4)$; its **length** $p$ is
  the number of entries. Two lists of the same length are a **pair**: the
  **lower** list $(l_1, \dots, l_p)$ and the **upper** list $(u_1, \dots, u_p)$.
- **Kronecker delta** $\delta(a, b)$: the number 1 if the labels $a$ and $b$ are
  equal and 0 if they are different.
- **Matrix, entry, row, column**: a matrix is a rectangle of numbers; the number in
  row $i$ and column $j$ is the entry $M_{ij}$. A **0/1 matrix** has only the
  entries 0 and 1.
- **Outer[delta, lower, upper]**: the author's Mathematica name for the $p \times p$
  matrix with the entries $M_{ij} = \delta(l_i, u_j)$: row $i$ belongs to the lower
  label $l_i$, column $j$ to the upper label $u_j$.
- **Permutation**: a rearrangement of $p$ objects; we describe it by the list
  $(\sigma(1), \dots, \sigma(p))$ that says where object $i$ goes. There are
  $p! = 1 \cdot 2 \cdots p$ permutations of $p$ objects ($p!$ is read
  "$p$ factorial").
- **Inversion**: a pair of places $i < j$ with $\sigma(i) > \sigma(j)$, that is, two
  objects that the permutation puts in the opposite order.
- **Sign of a permutation**: $\mathrm{sign}(\sigma) = (-1)^{N}$, where $N$ is the
  number of inversions: $+1$ for an **even** permutation (even $N$), $-1$ for an
  **odd** one. A **transposition** exchanges two objects.
- **Determinant** (Leibniz formula): for a $p \times p$ matrix $M$,
  $\det M = \sum_{\pi} \mathrm{sign}(\pi)\, M_{1\pi(1)} M_{2\pi(2)} \cdots
  M_{p\pi(p)}$, a sum of $p!$ products, one for every permutation $\pi$.
- **Generalized Kronecker delta**: the number
  $\delta^{u_1 \dots u_p}_{l_1 \dots l_p} = \det[\delta(l_i, u_j)]$; the author
  writes it k$\delta$[lower, upper].
- **GKD**: the name of the Rust function of the Revision program that computes the
  generalized Kronecker delta by the permutation rule proved in this notebook.
- **Exhaustive test**: a test of every possible case. **Pseudo-random numbers**:
  numbers made by a fixed recipe that look random; the recipe starts from a number
  called the **seed**, and the same seed gives the same numbers on every computer.
- **Pigeonhole principle**: if more than $n$ objects are put into $n$ boxes, some
  box holds two objects.
- **Rust, cargo, program**: Rust is a programming language; cargo builds a Rust
  **crate** (a folder with a file `Cargo.toml` and source files) into a program file
  that the computer runs.
- **Revision record**: a file committed under `Revision/` that holds a result of the
  Revision computations. **Byte for byte**: two files are equal in every byte, so
  they are the same file.
```

Text cell:

4. The physical and mathematical situation

Why the delta is needed. In eight dimensions Lovelock's equation (4.38), which the author's notebook quotes, adds to Einstein's tensor two more tensors built from products of two and of three curvature tensors. Written out, the tensor of order k is a sum over $2k$ upper and $2k$ lower coordinate labels plus one free pair, and every term is weighted by a generalized Kronecker delta with $p = 2k + 1$ upper and $2k + 1$ lower labels. For the 64 components of the tensor of order $k = 3$ the program ‘lovelock_gkd‘ evaluates the delta 495,360 times (record ‘Revision/gkd_lovelock/results/lovelock-report.json‘, counter ‘gkdCalls‘). So the delta must be right and fast.

The author's definition. The Revision record ‘Revision/gkd_lovelock/results/PROVENANCE_OF_THE_COMPUTATION.md‘ quotes it from the input cell In[54] of the author's notebook (with δ written as delta here):

```
    kdelta[lower_, upper_] /; Length[lower] == Length[upper] :=
        Det[Outer[delta, lower, upper]]
```

In words: for two lists of the same length p, build the $p \times p$ matrix $M_{ij} = \delta(l_i, u_j)$ and take its determinant. For lists of different lengths the definition gives nothing (Mathematica leaves the expression unevaluated). For $p = 1$ the matrix is the single number $\delta(l_1, u_1)$, so the generalized delta is the ordinary Kronecker delta. For $p = 2$,

$$\delta^{u_1 u_2}_{l_1 l_2} = \delta(l_1, u_1)\,\delta(l_2, u_2)
  - \delta(l_1, u_2)\,\delta(l_2, u_1),$$

by the formula $\det = M_{11} M_{22} - M_{12} M_{21}$ of a 2×2 determinant.

Theorem (the rule GKD). Let $M_{ij} = \delta(l_i, u_j)$. Then $\det M = 0$ when a label appears twice in the lower list, or twice in the upper list, or when some lower label is missing from the upper list; otherwise $\det M = \mathrm{sign}(\sigma)$, where $\sigma(i)$ is the place of l_i in the upper list.

Proof, case by case.

(a) Two equal lower labels, $l_i = l_k$ with $i \ne k$. Then row i and row k of M are equal, because $M_{ij} = \delta(l_i, u_j) = \delta(l_k, u_j) = M_{kj}$ for every column j. Exchanging two rows of a matrix changes the sign of its determinant; exchanging two EQUAL rows does not change the matrix. So $\det M = -\det M$, which gives $2 \det M = 0$ and $\det M = 0$.

(b) Two equal upper labels, $u_j = u_k$. Then columns j and k are equal, and the same argument for columns (a matrix and its transpose have the same determinant) gives $\det M = 0$.

(c) Some lower label l_i equals no upper label. Then row i is all zeros. Every product in the Leibniz formula contains exactly one entry of row i, so every product is zero, and $\det M = 0$.

(d) Otherwise the p lower labels are different, the p upper labels are different, and every lower label appears in the upper list. Then l_i equals

exactly one upper label, $u_{\sigma(i)}$. Different lower labels sit at different places, so σ sends the places $1, \dots, p$ to the places $1, \dots, p$ without repetition: σ is a permutation. Row i of M has a single 1, in column $\sigma(i)$. In the Leibniz formula the product for a permutation π is $M_{1\pi(1)} \cdots M_{p\pi(p)}$; it is 1 if $\pi(i) = \sigma(i)$ for every i and 0 otherwise. So only the term $\pi = \sigma$ survives, and $\det M = \mathrm{sign}(\sigma) \cdot 1 = \mathrm{sign}(\sigma)$. End of proof.

The rule needs only about $p^2/2$ comparisons of two numbers, while the Leibniz formula adds $p!$ products. For $p = 7$ that is 21 comparisons against 5,040 products.

How many pairs give $+1$, -1 and 0. A lower list of p DIFFERENT labels out of 8 can be chosen in $8 \cdot 7 \cdots (8 - p + 1) = 8!/(8 - p)!$ ways (8 choices for the first label, 7 for the second, and so on). The delta is nonzero exactly when the upper list holds the same p labels in some order: $p!$ orders. Hence the number of pairs with a nonzero delta is

$$N_{\ne 0}(p) = \frac{8!}{(8 - p)!}\, p!,$$

out of $8^p \cdot 8^p = 8^{2p}$ pairs. For $p \ge 2$ exactly half of the $p!$ orders are even. To see this, exchange the first two labels of the upper list. In the list σ this exchanges the values 1 and 2 (the places of these two labels). The two entries of σ that hold the values 1 and 2 change their relative order, so the pair they form becomes an inversion if it was none, and stops being one if it was one. Every other pair of entries is compared as before: a pair that contains neither of the two entries is unchanged, and an entry with a value of 3 or more is larger than both 1 and 2, so its comparison with either of them gives the same answer. Hence the number of inversions changes by exactly one: the exchange turns every even order into an odd one and back, and so pairs the even orders one to one with the odd orders. For $p = 1$ the only order is the identity, which is even. So $p = 1$ gives 8 values $+1$; $p = 2$ gives $56 \cdot 2 = 112$ nonzero values, 56 of each sign; $p = 3$ gives $336 \cdot 6 = 2016$, 1008 of each sign.

Nine labels in eight dimensions. A list of 9 labels taken from 8 must repeat a label (pigeonhole principle), so by case (a) every delta with $p \ge 9$ is zero. The Lovelock tensor of order k needs $p = 2k + 1$: $p = 3, 5, 7$ for $k = 1, 2, 3$ and $p = 9$ for $k = 4$. That is why the Lovelock sum in eight dimensions stops at $k = 3$.

Status. The theorem is PROVED above (exact). The comparisons below are COMPUTED checks of the proof and of the two programs.

Text cell:

5. The literal definition: a determinant of zeros and ones

The next cell imports the packages and defines two functions. ‘outer_delta(lower, upper)‘ builds the matrix Outer[delta, lower, upper] as a list of rows. ‘kdelta(lower, upper)‘ is the author’s definition: it refuses two lists of different lengths and returns the determinant of that matrix, computed EXACTLY by sympy (‘sp.Matrix(...).det()‘ gives a whole number, not a decimal approximation). Because many different pairs of lists give the same 0/1 matrix, ‘kdelta‘ remembers every

determinant it has computed in the dictionary ‘DETERMINANTS‘ and computes each matrix only once.

Then it evaluates the five examples of the Revision record ‘python-lovelock-report.json‘ (check ‘gkd_examples‘), whose lists use the labels 1, 2, 3, 4 (any whole numbers can serve as labels: only equality of two labels matters).

In [2]:

```

```
The next cell draws the matrix Outer[delta, lower, upper] for three pairs of lists
of length 4, one for each kind of value: the upper list $(x_2, x_1, x_4, x_3)$ is the
lower list with two exchanges (an even permutation, value $+1$); the upper list
$(x_2, x_3, x_4, x_1)$ moves every label one place (a cycle of four, which is three
exchanges: odd, value $-1$); and the lower list $(x_1, x_2, x_3, x_3)$ repeats a
label (two equal rows, value $0$). Each entry is written into its square; dark
squares are the ones. ‘ax.imshow‘ draws a matrix as a picture of coloured squares,
and ‘ax.text(column, row, ...)‘ writes a number at the centre of a square.
```

```
## 6. The rule behind GKD: the sign of a permutation

The next cell writes the rule of the theorem as the Python function ‘gkd‘. It
follows the Rust function GKD of ‘Revision/gkd_lovelock/code/src/gkd.rs‘ step by
step:

1. It walks through the upper list and records in the dictionary ‘position‘ the
   place of every label; a label seen twice means two equal columns: value 0
```

```
   (case b).
2. It walks through the lower list and looks up the place of every label; a label
   that is not in the upper list means a row of zeros: value 0 (case c). The places
   form the list ‘sigma‘.
3. If a place occurs twice in ‘sigma‘, a label occurs twice in the lower list: value
   0 (case a).
4. Otherwise ‘sigma‘ is a permutation. The cell counts its inversions (pairs of
   places $i < j$ with ‘sigma[i] > sigma[j]‘) and returns $+1$ for an even count and
   $-1$ for an odd count (case d).

The cell then checks that ‘gkd‘ and ‘kdelta‘ agree on the five examples.
```

In [4]:

```
def inversions(sigma):
    """The number of pairs of places i < j with sigma[i] > sigma[j]."""
    return sum(1 for i in range(len(sigma)) for j in range(i + 1, len(sigma))
               if sigma[i] > sigma[j])

def gkd(lower, upper):
    """The rule GKD (the Rust function GKD, written in Python): the sign of the
    permutation that carries the lower list into the upper list, or 0."""
    if len(lower) != len(upper):
        raise ValueError("gkd needs two index lists of the same length")
    position = {}  # label -> its place in the upper list
    for place, label in enumerate(upper):
        if label in position:
            return 0  # a label twice in the upper list: equal columns (case b)
        position[label] = place
    sigma = []  # sigma[i]: the place in the upper list of the i-th lower label
    for label in lower:
        if label not in position:
            return 0  # a lower label missing above: a row of zeros (case c)
        sigma.append(position[label])
    if len(set(sigma)) < len(sigma):
        return 0  # a label twice in the lower list: equal rows (case a)
    return 1 if inversions(sigma) % 2 == 0 else -1  # even +1, odd -1 (case d)

for lower, upper, stated in EXAMPLES:
    say(f"gkd({list(lower)}, {list(upper)}) = {gkd(lower, upper)}")
check(all(gkd(lower, upper) == kdelta(lower, upper) for lower, upper, _ in EXAMPLES),
      "gkd and kdelta agree on the five examples")
```

Green panels are even permutations (sign +1), orange ones odd (sign -1): three of each, and each sign equals the determinant of the matrix. (Notebook 11a, figure 2.)

7. Every pair of lists of length 1, 2 and 3

The next cell compares ‘gkd‘ with the literal determinant ‘kdelta‘ for EVERY pair of index lists of length $p = 1, 2, 3$ over the eight labels: 8^{2p} pairs for each p, that is $64 + 4096 + 262144 = 266304$ pairs. ‘itertools.product(range(8), repeat=p)‘ produces all 8^p lists of length p with entries $0, \dots, 7$. The cell counts how often each value occurs and prints, for each p, the number of pairs and the counts of $+1$, -1 and 0. It takes a few seconds. At the end it reads the Revision’s Wolfram verification ‘wolfram-gkd-report.json‘, whose checks ‘gkd_equals_kdelta_exhaustive_length_1‘ to ‘_3‘ compared GKD with the literal determinant on the same 266,304 pairs, and requires that they found no difference.

There are 56 red squares on the diagonal, where the upper list equals the lower list (the 8 lists with two equal labels are white), and 56 blue squares at the mirrored places, where the two labels are exchanged; the other 3984 values are 0. (Notebook 11a, figure 3.)

```
The next cell draws the three counts for each length $p = 1, 2, 3, 4$ as bars on a
logarithmic vertical axis (each step of the axis is a factor of 10, so that 8 and
16 million fit into one picture). For $p = 1, 2, 3$ the bars are the counts measured
above; for $p = 4$ they come from the formula (the Rust self-test of section 10
compares all 16,777,216 pairs of length 4 but prints only the number of
disagreements). A count of zero cannot be drawn on a logarithmic axis; it is marked
"none".

## 8. Longer lists: random pairs and the pigeonhole principle

For $p = 4$ to $9$ there are too many pairs to test them all in Python ($8^{18}$ for
```

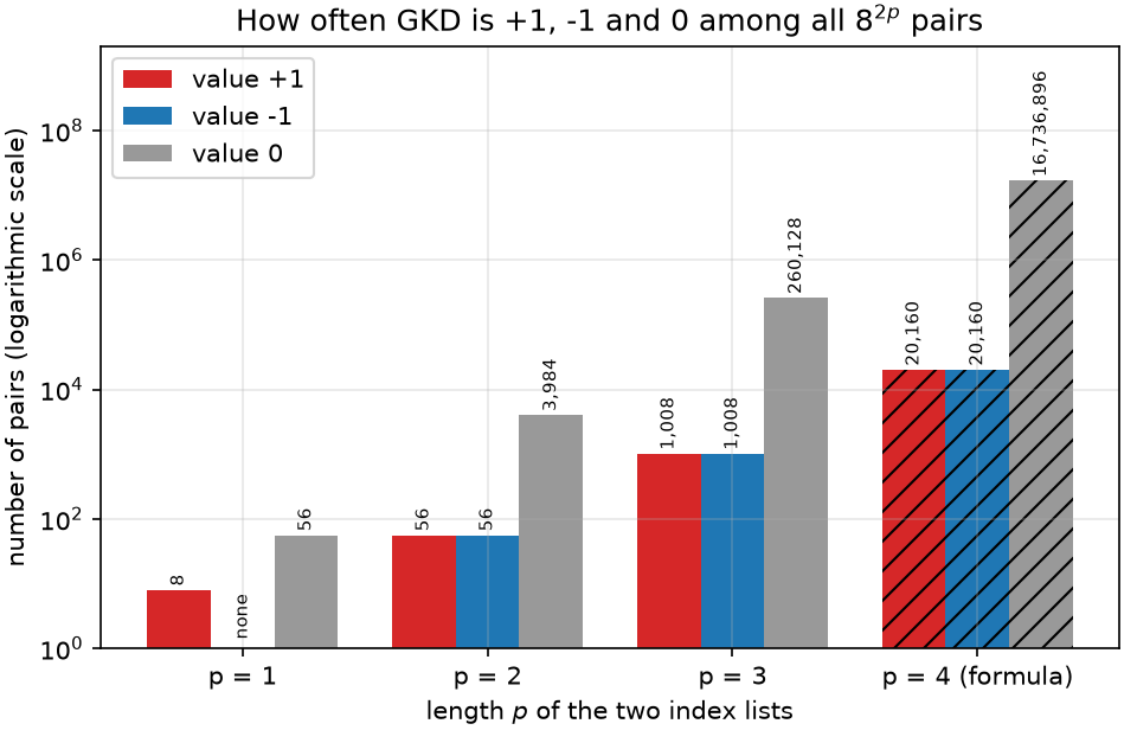

Figure 306: The number of pairs of index lists of length p over the eight labels whose generalized Kronecker delta is +1 (red), -1 (blue) and 0 (grey), for $p = 1$ to 4, on a logarithmic vertical axis; the hatched bars of $p = 4$ come from the formula $N = 8!/(8-p)! \cdot p!$ for the nonzero values, the others are counted by the notebook. The value 0 dominates more and more: for $p = 4$ only 40,320 of the 16,777,216 pairs are nonzero, half of them +1 and half -1. (Notebook 11a, figure 4.)

$p = 9$). The next cell tests 2,000 pseudo-random pairs of each length. The generator ‘np.random.default_rng(12345)‘ makes the same numbers on every computer. For an even sample number ‘s‘ the lower list is the upper list rearranged in random order (‘rng.permutation(p)‘ is a random arrangement of the places), so the delta is nonzero whenever the upper list has p different labels; for an odd ‘s‘ the lower list is a second, independent random list, and the delta is almost always zero. The cell counts the disagreements between ‘gkd‘ and ‘kdelta‘ and the number of nonzero values. Because a list of 9 labels from 8 must repeat a label, every value of length 9 must be zero. The cell takes a few seconds: sympy computes the determinants of about ten thousand new matrices of sizes 4×4 to 9×9 (the cell prints how many different matrices ‘kdelta‘ has met so far).

In [10]:

```
How many nonzero values should we expect? In an even sample the delta is nonzero
exactly when the $p$ random labels of the upper list are all different. Each label
is one of 8 with equal chance, so the chance that $p$ labels are all different is

$$r_p = \frac{8}{8} \cdot \frac{7}{8} \cdots \frac{8 - p + 1}{8}
      = \frac{8!}{(8 - p)!\, 8^p}$$

(the second label must avoid the first, the third the first two, and so on; this is
the "birthday problem" with 8 possible birthdays). In an odd sample the chance is
$q_p = N_{\ne 0}(p)/8^{2p}$, tiny for $p \ge 4$. With 1,000 samples of each kind the
expected number of nonzero values is $1000\,(r_p + q_p)$, and the usual random
scatter of such a count (its standard deviation) is
$\sqrt{1000\, r_p (1 - r_p) + 1000\, q_p (1 - q_p)}$. The next cell checks that every
count lies within 5 standard deviations of its expectation (a count further away
would happen by chance less than once in a million times).

## 9. Why the rule is needed: the cost of the determinant

The Leibniz formula adds $p!$ products of $p$ entries; the rule GKD makes
$p(p - 1)/2$ comparisons of places. The next cell prints both numbers for
$p = 1, \dots, 9$, together with the number $8^{2p}$ of all pairs of lists of length
$p$, and draws them. Then it MEASURES the difference: it times 200 evaluations of
‘gkd‘ and 200 exact determinants of sympy (without the memory of ‘kdelta‘) on the
same pairs of lists of length 7 and checks that the rule is more than ten times
faster. The measured times differ from computer to computer and from run to run, so
they are not printed (the printed output of a notebook of this book is the same on
every run); only the result of the comparison is.
```

In [12]:

## 10. The Rust program: the self-test of GKD

The Revision computes the Lovelock tensors with the Rust program `lovelock_gkd`
(crate `Revision/gkd_lovelock/code`). Its function GKD is the rule of section 6, and
its function `kdelta_det` is the literal Leibniz determinant of
Outer[delta, lower, upper] (it runs through all $p!$ permutations with Heap's
method, which changes one permutation into the next by one exchange). Its command
`gkd-selftest` compares the two:

- for $p = 1, 2, 3, 4$ (the option `--exhaustive-max 4`), EVERY pair of lists of
  length $p$ over the 8 labels: $64 + 4096 + 262144 + 16777216$ pairs;
```

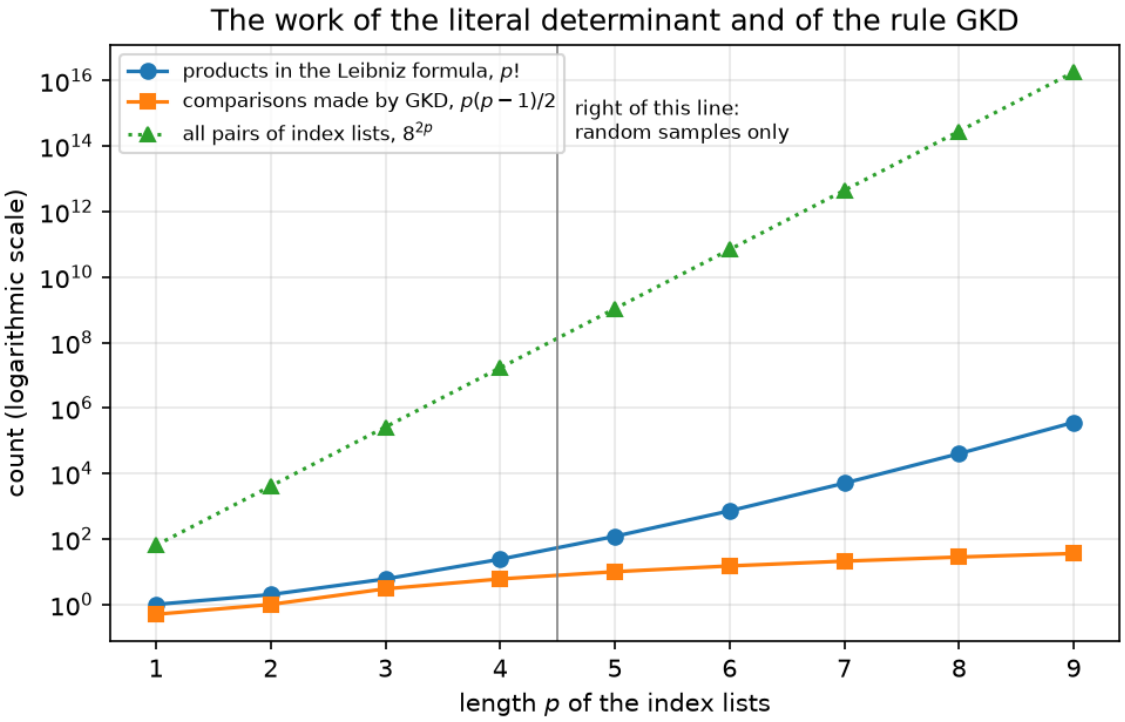

Figure 307: Work per evaluation of the generalized Kronecker delta for index lists of length p: the Leibniz formula of the determinant adds $p!$ products (circles), the rule GKD makes $p(p-1)/2$ comparisons (squares; drawn at 0.5 for $p = 1$, where it makes none); the triangles count all 8^{2p} pairs of index lists over eight labels. The vertical axis is logarithmic. For $p = 9$ the formula needs 362,880 products against 36 comparisons, and the number of pairs grows so fast that only $p \leq 4$ can be tested exhaustively. (Notebook 11a, figure 5.)

```
- for $p = 5, \dots, 9$, 200,000 pseudo-random pairs each from its own fixed
  generator (xorshift64*), half of them rearrangements (Fisher-Yates shuffle) and
  half independent lists, as in section 8.

It writes the result to the file ‘gkd-selftest.json‘ in the folder given by
‘--output‘, without any time in it, so the file is the same on every run. The
committed Revision record ‘Revision/gkd_lovelock/results/gkd-selftest.json‘ was
written by the same command. The run takes 7 to 13 minutes, most of it in the
200,000 literal determinants of $9 \times 9$ matrices: longer than the limit of 7
minutes that this book sets for one computation. So this notebook builds the
program but does not run the self-test; it reads the record.

The next cell builds the program with cargo, through the helper ‘rust_program‘ of the
set-up cell, which runs ‘cargo build --release‘ for the crate and returns the path of
the program file (‘lovelock_gkd.exe‘ on Windows). When the program file is missing,
cargo compiles it: on the computer that built the book this took 4 seconds; a slow
computer may need up to a minute. When the program is up to date, cargo only checks
that and needs about a second. The crate has no dependencies, so cargo downloads
nothing.
```

In [13]:

```
program = rust_program("Revision/gkd_lovelock/code/Cargo.toml", "lovelock_gkd")
COMMAND = ["lovelock_gkd", "gkd-selftest", "--exhaustive-max", "4", "--output", "FOLDER"]
say("To repeat the self-test (7 to 13 minutes), run in the folder of the program: "
    + " ".join(COMMAND))
```

Out [13]:

```
Rust program lovelock_gkd is built and ready.
To repeat the self-test (7 to 13 minutes), run in the folder of the program: lovelock_gkd
    gkd-selftest --exhaustive-max 4 --output FOLDER
```

Text cell:

```
The next cell reads the record ‘Revision/gkd_lovelock/results/gkd-selftest.json‘ of
the run of ‘lovelock_gkd gkd-selftest --exhaustive-max 4 --output FOLDER‘ (the cell
before prints this command). Its entry ‘results‘ holds one row per length: the mode
(‘exhaustive‘ or ‘random‘), the number of pairs, for the random lengths the number
of nonzero values, and the number of disagreements between GKD and the literal
determinant. The cell prints the rows as a table and checks the verdict SUCCESS of
the record, that the rows cover the lengths 1 to 9 with no disagreement and that
the length 4 was tested exhaustively on all 16,777,216 pairs, and that the program
file that repeats the run is built. To repeat the run yourself, run the printed
command in a terminal, in the folder ‘Revision/gkd_lovelock/code/target/release‘,
with a folder of your choice in place of FOLDER: it writes ‘gkd-selftest.json‘ into
that folder, and the file must equal the record byte for byte.
```

The record just read is now read as JSON (a text format of names and numbers),
and its numbers are compared with the birthday formula of section 8. In the
program's random samples one half are rearrangements and one half independent lists,
100,000 each, so the expected number of nonzero values of length $p$ is
$100000\,(r_p + q_p)$, with the standard deviation of section 8. The next cell checks
that every count lies within 5 standard deviations of its expectation, and that the
count of length 9 is exactly 0. Then it draws the chance $r_p$ that $p$ random
labels out of 8 are all different, with the measured fractions: the number of
nonzero values found among ALL the samples of one length, divided by the number of
rearranged samples (1,000 in the Python test of section 8, 100,000 in the Rust
```

test). This fraction should be close to $r_p + q_p$; the independent pairs add the
small chance q_p, which is at most 0.0025 (for $p = 4$, $q_4 = 40320/8^8$) and
invisible on the logarithmic axis.

Rust p = 6: counted   7812, expected   7711.6 +-   84.4  (1.19 standard deviations away)
Rust p = 7: counted   1949, expected   1927.2 +-   43.5  (0.50 standard deviations away)
Rust p = 8: counted    244, expected    240.9 +-   15.5  (0.20 standard deviations away)
Rust p = 9: counted      0, expected      0.0 +-    0.0  (0.00 standard deviations away)
PASS the Rust counts of nonzero values agree with the birthday formula
```

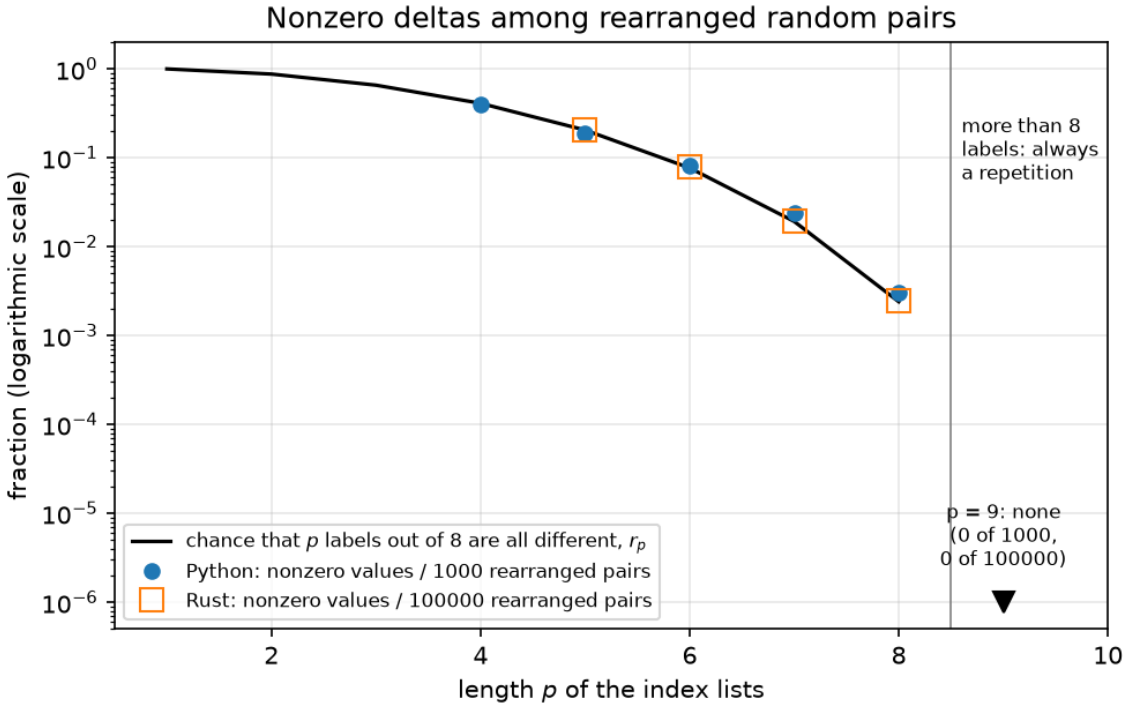

Figure 308: The chance $r_p = 8!/((8-p)!\,8^p)$ that p random labels out of eight are all different (line), which is the chance that a rearranged random pair of index lists has a nonzero generalized Kronecker delta, with the measured fractions: the nonzero values found among all the samples of one length divided by the number of rearranged samples, for the Python samples of this notebook (dots) and the Rust self-test (open squares); the independent samples add at most 0.0025. The vertical axis is logarithmic. The measured points follow the formula. For $p = 9$ no list can have nine different labels, so the chance and both measured fractions are 0, which a logarithmic axis cannot show; the black triangle at the bottom edge marks them. Text cell:

11. The Revision records quoted in this notebook

This notebook quotes check names and numbers from five Revision records. Two of them were already compared in full: the self-test record ‘gkd-selftest.json‘ (byte for byte, section 10) and the value counts of ‘wolfram-gkd-report.json‘ (section 7). The next cell reads the records once more and checks the rest of what the text quotes, so that a later change of a record cannot pass unnoticed:

- every check quoted from the sympy verification ‘python-lovelock-report.json‘ and from the Wolfram verification ‘wolfram-gkd-report.json‘ is present in the record with the verdict PASS;
- the record ‘PROVENANCE_OF_THE_COMPUTATION.md‘ contains the author’s definition as quoted in section 4 (the part after the name kδ, which is written with a Greek letter there);
- the counter ‘gkdCalls‘ of the order-3 sum in ‘lovelock-report.json‘ is 495,360, the number quoted in section 4.

The function ‘verdicts(path)‘ returns, for one report, a dictionary from the name of each check to its verdict. The reports store their checks in one of two forms: a list of entries, each with a ‘name‘ and a ‘verdict‘, or a dictionary from the name to an entry whose field ‘passed‘ is true or false; the function reads both.

In [16]:

```
def verdicts(path):
    """{check name: "PASS" or "FAIL"} of the Revision report at ‘path‘."""
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))

```
## 12. What this notebook showed

- The author's generalized Kronecker delta, the determinant of the 0/1 matrix
  Outer[delta, lower, upper], is $+1$, $-1$ or $0$: it is zero when a label repeats
  in either list or a lower label is missing above, and otherwise it is the sign of
  the permutation that carries the lower list into the upper list (PROVED in
  section 4).
- The Python rule `gkd` and the literal determinant agree on all 266,304 pairs of
  lengths 1 to 3 and on 12,000 random pairs of lengths 4 to 9 (COMPUTED). The counts
  of the values (8; 56 and 56; 1008 and 1008 nonzero values for $p = 1, 2, 3$) follow
  the formula $8!/(8 - p)! \cdot p!$ and equal those of the Revision's Wolfram
  verification.
- Every delta with 9 or more indices vanishes in eight dimensions, so the Lovelock
  tensor of order 4 is zero and Lovelock's sum stops at order 3.
- The rule costs $p(p-1)/2$ comparisons instead of $p!$ products and is measured to
  be more than ten times faster already for $p = 7$.
- The Revision Rust program `lovelock_gkd`, built here with cargo, compared GKD with
  the literal determinant on 16,777,216 pairs of length 4 and 1,000,000 random
  pairs of lengths 5 to 9 without a single disagreement, and wrote the Revision
  record `gkd-selftest.json` again, byte for byte.
- Every check and number that the notebook quotes from the Revision records (the
  sympy and Wolfram verifications, the record of the author's definition and the
  counter of the order-3 Lovelock sum) is present in them, and every quoted check
  has the verdict PASS.
```

11.9 Line-by-line walk-through of Notebook 11a

The notebook has 17 code cells, In [1] to In [17]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted, then explained. A line that starts with `#`, and the part of a line after `#`, is a **comment**, which Python skips; it is there for the reader. Inside a function the text in triple quotes below the `def` line is its **docstring**, a description that Python stores but does not run; to keep the quotations short, docstrings are left out of them where the explanation repeats them, and a long figure caption passed to `save_figure` is shortened to `...` (the full caption is printed under the figure in Section 11.8). Because Notebook 11a is the first notebook of this chapter, its set-up cell is explained here in full; the walk-throughs of Notebooks 11b and 11c refer back to this explanation.

In [1], the set-up cell. Its first part, down to the heading THE SET-UP between two lines of `=` signs, consists of comment lines that repeat the complete run instructions of Section 11.7, so that the notebook file carries its own instructions. The code below the heading computes no physics; it is the same in every notebook of the book except for the line that names the notebook and, in notebooks without Rust, the two lines `import shutil` and `import subprocess` and the helper `rust_program`, which such notebooks lack (all three are explained below, the helper at the end).

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module**, a part of Python or of an installed package, so that the code can use its functions. `json`, `os`, `textwrap` and `pathlib` come with Python. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
import shutil  # finds the program cargo
import subprocess  # runs cargo and the Rust programs
```

These load the plotting package matplotlib, its drawing functions under the short name `plt`, the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell, and the two modules that a notebook with Rust needs: `shutil` can look for a program on the computer, and `subprocess` can start another program and collect what it prints.

```
NOTEBOOK_ID = "11a"  # this notebook: chapter 11, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"11a"`; the figures and the captions file are named after it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs each time it is called. `Path.cwd()` is the folder in which Jupyter runs the notebook (the folder of the notebook file), and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it, and `[here, *here.parents]` is the list that starts with `here` and continues with them (the star unpacks one list into another). The `for` loop visits these folders one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains the file `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If no folder does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
REPO = find_repository_root()
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

(The comment lines above each of these two lines are left out.) The first line calls the function and names the result `REPO`. It is never printed, because it differs from computer to computer and the printed output of a notebook must not. The second line chooses where files are written: `os.environ` holds the **environment variables** of the running program (named texts it receives from the computer), and `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and `str(REPO)` otherwise. When you run the notebook the variable is not set, so files go into the repository; the book's checking tool sets it to a scratch folder, so that a check run changes nothing in the repository.

```
def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small helpers (docstrings left out). `repository_file` gives the full path of a repository file, for READING a Revision record. `output_file` gives the full path at which to WRITE a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the file's folder and any missing folder above it, and does nothing if they exist.

```
def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of the book: `str(text)` turns any value into text, and `textwrap.fill` breaks it at blanks and starts every line after the first with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns matplotlib to its built-in settings, so the figures are the same on every computer. `plt.rcParams.update({...})` then sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid (`grid.alpha` 0.3 means 30 per cent opaque). The braces make a **dictionary**, a collection of pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: a name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/11a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The two comment lines explain the last line, which writes an empty JSON dictionary and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored as bytes and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

(Docstring and three comment lines left out.) `setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far: the figures are numbered 1, 2, 3, and a cell run twice keeps its number. The file name joins the notebook id, the number and the name, for example `11a_1_outer_delta_matrices.png`. `fig.savefig` writes a PNG picture file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time. The caption is stored, the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys), `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list**, an ordered collection in square brackets. `check` is behind every check of the book: if `condition` is false, `raise AssertionError(...)` stops the notebook with an error that names the check (an `if` is used instead of the statement `assert`, because Python started with its optimising option skips every `assert`); otherwise the name is appended to `PASSED` and the line PASS name is printed, followed by a second line naming the Revision record when `record` is given. `record=None` makes that argument optional.

```
def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")
```

`report` prints a key number as a line RESULT label = value, with the unit when one is given (`a if c else b` is `a` when `c` is true and `b` otherwise; an empty string counts as false). `all_checks_passed` prints the last line of the notebook with the number of checks that passed; `len` is the length of a list.

```
def rust_program(manifest, binary):
    if shutil.which("cargo") is None:
        raise FileNotFoundError(
            "cargo was not found: install Rust from https://rustup.rs, open a new "
            "terminal, activate the environment and start JupyterLab again")
    crate = (REPO / manifest).parent  # the folder that holds Cargo.toml
```

The helper that builds a Rust program (docstring left out). `shutil.which("cargo")` searches the folders where the computer looks for programs and returns `None` (Python's "nothing") when cargo is not installed; the notebook then stops with a message that says how to install it. `crate` is the folder of the crate, the folder that holds the file `Cargo.toml` named by `manifest`.

```
    completed = subprocess.run(
        ["cargo", "build", "--release", "--manifest-path", str(REPO / manifest),
         "--target-dir", str(crate / "target")],
        capture_output=True, text=True, encoding="utf-8", errors="replace")
```

`subprocess.run([...])` starts the program cargo with the words of the list as its command line, waits until it ends and returns a record of the run, here named `completed`. The command is the build command of the run instructions: build the crate in the release (optimised) mode and put the result into the folder `target` next to `Cargo.toml`. `capture_output=True` collects what cargo prints instead of showing it; `text=True` with `encoding="utf-8"` turns the collected bytes into text, and `errors="replace"` replaces any byte that is not valid text by a placeholder instead of stopping.

```
    if completed.returncode != 0:  # show the end of cargo's error message
        print(completed.stderr[-3000:])
        raise RuntimeError(f"cargo build failed for {manifest}")
    for file_name in (binary, binary + ".exe"):  # Linux and macOS; Windows
        path = crate / "target" / "release" / file_name
        if path.is_file():
            say(f"Rust program {binary} is built and ready.")
            return path
    raise FileNotFoundError(f"cargo built {manifest} but {binary} is missing")
```

Every program ends with a **return code**, 0 for success. If cargo failed, the last 3,000 characters of its error output (`stderr[-3000:]`, the slice from 3,000 characters before the end to the end) are

printed and the notebook stops. Otherwise the loop looks for the program file without and with the ending `.exe` (Windows adds it), prints that the program is ready and returns its path. If neither file exists, the notebook stops with a message.

```
say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

The last line prints the cell's only output, Set-up of notebook 11a complete: repository folder found, helpers defined. (Two strings written next to each other inside the parentheses are joined into one.)

In [2], the literal definition.

```
import itertools  # loops over all lists of labels, and over all permutations
import math  # factorials n! and the numbers n!/(n-p)!
import re  # regular expressions: reads numbers out of the texts of the records
import time  # a stopwatch (used inside one check; no time is ever printed)

import numpy as np  # arrays of numbers and pseudo-random numbers
import sympy as sp  # exact algebra: sympy computes determinants exactly
```

Six more modules: `itertools` produces all lists of labels and all permutations; `math` has `math.factorial(p)` $= p!$ and `math.perm(n, p)` $= n!/(n-p)!$; `re` reads numbers out of text with **regular expressions** (patterns of characters); `time` provides a stopwatch; numpy (short name `np`) handles arrays of numbers and makes pseudo-random numbers; sympy (short name `sp`) does exact algebra.

```
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # the labels 0..7 by name
```

The list of the eight coordinate names; `NAMES[0]` is `"x1"` and `NAMES[7]` is `"x0"`, because Python counts places from 0.

```
def outer_delta(lower, upper):
    return [[1 if a == b else 0 for b in upper] for a in lower]
```

The matrix `Outer[delta, lower, upper]` as a list of rows. The inner part `[1 if a == b else 0 for b in upper]` is a **list comprehension**: for each upper label `b` it writes 1 if `b` equals the lower label `a` and 0 otherwise; that is one row. The outer comprehension makes one such row for each lower label `a`. So the entry in row i and column j is $\delta(l_i, u_j)$, exactly the author's matrix.

```
DETERMINANTS = {}  # memory: a matrix (a tuple of rows) -> its determinant

def kdelta(lower, upper):
    if len(lower) != len(upper):
        raise ValueError("kdelta needs two index lists of the same length")
    matrix = tuple(tuple(row) for row in outer_delta(lower, upper))
    if matrix not in DETERMINANTS:  # each different matrix is computed only once
        DETERMINANTS[matrix] = int(sp.Matrix(matrix).det())
    return DETERMINANTS[matrix]
```

The author's definition, literally (docstring left out). Two lists of different lengths are refused with a `ValueError`, as Mathematica leaves the author's expression unevaluated. The matrix is turned into a **tuple** of tuples (a tuple is a list that cannot be changed; only such values can be keys of a dictionary). If this matrix has not been met before, sympy computes its determinant exactly (`sp.Matrix(matrix).det()`), `int` turns the result into a Python whole number, and it is stored in the dictionary `DETERMINANTS`. Many different pairs of lists give the same 0/1 matrix, so this memory saves most of the work.

```
EXAMPLES = [  # (lower list, upper list, value stated in the Revision record)
    ((1, 2), (1, 2), 1),
    ((1, 2), (2, 1), -1),
    ((1, 1), (1, 1), 0),
    ((1, 2, 3), (2, 3, 1), 1),
    ((1, 2, 3), (1, 2, 4), 0),
]
```

The five examples of the record check `gkd_examples` of `Revision/gkd_lovelock/results/python-lovelock-report.json`, each as a lower list, an upper list and the stated value.

```
for lower, upper, stated in EXAMPLES:
    say(f"kdelta[{list(lower)}, {list(upper)}] = {kdelta(lower, upper)}   "
        f"(the record states {stated})")
check(all(kdelta(lower, upper) == stated for lower, upper, stated in EXAMPLES),
      "the five examples give 1, -1, 0, 1, 0",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "check gkd_examples")
```

The loop takes the three parts of each example apart (`for lower, upper, stated in ...`) and prints the computed value next to the stated one; these are the first five output lines. `all(...)` is true when every comparison in the parentheses is true; the check prints PASS the five examples give 1, -1, 0, 1, 0 and the line naming the record. Look at the fourth example: the place of the lower label 1 in the upper list $(2, 3, 1)$ is 3, that of 2 is 1, that of 3 is 2; $\sigma = (3, 1, 2)$ has the two inversions $(3, 1)$ and $(3, 2)$, so the value is $+1$, as printed.

```
try:  # lists of different lengths must be refused, as in the author's definition
    kdelta((1,), (1, 2))
    refused = False
except ValueError:
    refused = True
check(refused, "kdelta refuses two lists of different lengths")
```

`try ... except ValueError` runs the line `kdelta((1,), (1, 2))` and catches the `ValueError` it should raise. (`(1,)` is a tuple with the single entry 1.) If the error comes, `refused` is set to `True`; if it did not come, the line after the call would set it to `False` and the check would fail. Output: PASS kdelta refuses two lists of different lengths. Two checks so far.

In [3], three matrices drawn (Figure 11a.1).

```
SHOWN = [  # (lower list, upper list) with labels 0..7 standing for x0..x7
    ((0, 1, 2, 3), (1, 0, 3, 2)),  # x2 x1 x4 x3: two exchanges, even
    ((0, 1, 2, 3), (1, 2, 3, 0)),  # x2 x3 x4 x1: a cycle of four, odd
    ((0, 1, 2, 2), (0, 1, 2, 3)),  # x3 twice in the lower list
]
fig, axes = plt.subplots(1, 3, figsize=(10.5, 3.9))
```

The three pairs of the examples of Section 11.3, written with the numbers 0 to 7 for x_0 to x_7. `plt.subplots(1, 3, ...)` makes a figure `fig` with one row of three panels, the **axes** (drawing areas) `axes[0]`, `axes[1]`, `axes[2]`, 10.5 by 3.9 inches in all.

```
for ax, (lower, upper) in zip(axes, SHOWN):
    matrix = np.array(outer_delta(lower, upper))
    ax.imshow(matrix, cmap="Blues", vmin=0.0, vmax=1.5)  # 0 white, 1 blue
```

`zip(axes, SHOWN)` pairs the first panel with the first pair of lists, and so on. For each, the matrix is built and turned into a numpy array; `ax.imshow` draws it as a picture of coloured squares, one per entry, with the colour map `Blues` running from white at `vmin` $= 0$ to dark blue at `vmax` $= 1.5$ (so that a 1 is a medium blue and the numbers stay readable).

```
    for i in range(4):  # i: the row
        for j in range(4):  # j: the column
            ax.text(j, i, str(matrix[i, j]), ha="center", va="center")
```

`range(4)` is $0, 1, 2, 3$. The two loops write each entry as text at the centre of its square; `ax.text(x, y, ...)` takes the horizontal position first, which is the column `j`, then the row `i`.

```
    ax.set_xticks(range(4), [NAMES[label] for label in upper])  # column labels
    ax.set_yticks(range(4), [NAMES[label] for label in lower])  # row labels
    ax.set_xlabel("upper list (one column per label)")
    ax.set_ylabel("lower list (one row per label)")
```

The columns are marked with the names of the upper labels and the rows with the names of the lower labels; then the two axes get their titles.

```
    value = kdelta(lower, upper)
    ax.set_title(f"determinant = {value:+d}" if value else "determinant = 0")
    ax.grid(False)  # no grid lines across the squares
fig.tight_layout()  # no overlapping labels
```

The exact determinant becomes the panel title; the format `:+d` writes a whole number with its sign, $+1$ or -1, and a value 0 (which counts as false) gives the title determinant $= 0$. The grid of the set-up cell is switched off for these pictures, and `fig.tight_layout()` moves the panels so that no labels overlap.

```
save_figure(fig, "outer_delta_matrices",
            "The matrix Outer of delta for three pairs of index lists of length 4; "
            ...)
check([kdelta(lower, upper) for lower, upper in SHOWN] == [1, -1, 0],
      "the three drawn matrices have the determinants +1, -1 and 0")
```

The figure is saved as `11a_1_outer_delta_matrices.png` with its caption (the output line Figure 11a.1 saved as ...), and the check confirms the three values $+1$, -1, 0 of Section 11.3 (third PASS line).

What Figure 11a.1 shows. Three 4×4 matrices of zeros and ones; rows are the lower labels, columns the upper labels, and blue squares are the ones. In the left and middle panels every row and every column has exactly one 1: these are permutation matrices, with determinant $+1$ (two exchanges) and -1 (three inversions). In the right panel the two rows of x_3 are equal and the column of x_4 is empty, so the determinant is 0, by case (a) and case (c) of the theorem at once.

In [4], the rule GKD in Python.

```
def inversions(sigma):
    return sum(1 for i in range(len(sigma)) for j in range(i + 1, len(sigma))
               if sigma[i] > sigma[j])
```

The number of inversions of a list `sigma` (docstring left out): for every pair of places `i < j` (the inner range starts at `i + 1`) it counts 1 when the entries stand in the wrong order, and `sum` adds the ones.

```
def gkd(lower, upper):
    if len(lower) != len(upper):
        raise ValueError("gkd needs two index lists of the same length")
    position = {}  # label -> its place in the upper list
    for place, label in enumerate(upper):
        if label in position:
            return 0  # a label twice in the upper list: equal columns (case b)
        position[label] = place
```

The rule of Section 11.3, step by step (docstring left out). `enumerate(upper)` gives each upper label together with its place 0, 1, 2, ... A label already in the dictionary `position` has been seen before: two equal columns, value 0. Otherwise its place is stored.

```
    sigma = []  # sigma[i]: the place in the upper list of the i-th lower label
    for label in lower:
        if label not in position:
            return 0  # a lower label missing above: a row of zeros (case c)
        sigma.append(position[label])
    if len(set(sigma)) < len(sigma):
        return 0  # a label twice in the lower list: equal rows (case a)
    return 1 if inversions(sigma) % 2 == 0 else -1  # even +1, odd -1 (case d)
```

For each lower label its place in the upper list is looked up; a label that is not there gives a row of zeros, value 0. A **set** keeps only different entries, so `len(set(sigma)) < len(sigma)` is true when a place occurs twice, which happens exactly when a label occurs twice in the lower list: value 0. Otherwise `sigma` is a permutation; `% 2` is the remainder after division by 2, so an even number of inversions gives $+1$ and an odd number -1.

```
for lower, upper, stated in EXAMPLES:
    say(f"gkd({list(lower)}, {list(upper)}) = {gkd(lower, upper)}")
```

```
check(all(gkd(lower, upper) == kdelta(lower, upper) for lower, upper, _ in EXAMPLES),
      "gkd and kdelta agree on the five examples")
```

The rule is applied to the five examples, which prints the five values 1, −1, 0, 1, 0, and the check confirms that it agrees with the literal determinant on all of them (the name `_` marks the stated value, which is not needed here). Fourth PASS line.

In [5], the six arrangements of three labels (Figure 11a.2).

```
lower = (0, 1, 2)  # x1, x2, x3
fig, axes = plt.subplots(2, 3, figsize=(9.0, 6.4))
signs = []
for ax, upper in zip(axes.flat, itertools.permutations(lower)):
    matrix = np.array(outer_delta(lower, upper))
    sigma = [upper.index(label) for label in lower]  # places of x1, x2, x3 above
    sign = 1 if inversions(sigma) % 2 == 0 else -1
    signs.append((sign, kdelta(lower, upper)))
```

A figure with two rows of three panels; `axes.flat` runs through the six panels one by one. `itertools.permutations(lower)` produces the $3! = 6$ arrangements of $(0, 1, 2)$. For each arrangement used as the upper list, `upper.index(label)` is the place of a label in it, so `sigma` lists the places of x_1, x_2, x_3; its sign comes from the inversions, and the pair (sign, exact determinant) is stored in `signs`.

```
    ax.imshow(matrix, cmap="Greens" if sign > 0 else "Oranges", vmin=0.0, vmax=1.4)
    for i in range(3):
        for j in range(3):
            ax.text(j, i, str(matrix[i, j]), ha="center", va="center")
    ax.set_xticks(range(3), [NAMES[label] for label in upper])
    ax.set_yticks(range(3), [NAMES[label] for label in lower])
```

Each matrix is drawn in green for an even and in orange for an odd arrangement, with its entries written in, its columns marked with the arranged upper labels and its rows with x_1, x_2, x_3.

```
    count = inversions(sigma)  # the number of inversions of sigma
    plural = "" if count == 1 else "s"  # 1 inversion, 2 inversions
    ax.set_title(f"sigma = {tuple(sigma)}, {count} inversion{plural}, "
                 f"sign {sign:+d}", fontsize=9)
    ax.grid(False)
fig.tight_layout()
```

The title of each panel gives σ, its number of inversions (with the right plural) and its sign.

```
save_figure(fig, "six_permutations",
            "All six arrangements of the labels $x_1, x_2, x_3$. Each panel shows "
            ...)
check(all(sign == det for sign, det in signs) and
      sorted(sign for sign, _ in signs) == [-1, -1, -1, 1, 1, 1],
      "the six arrangements of three labels: three even, three odd, sign = determinant")
```

The figure is saved, and the check confirms two things: every sign from the inversions equals the exact determinant, and the sorted list of the six signs is three times -1 and three times $+1$, half even and half odd as Section 11.4 proved. Fifth PASS line.

What Figure 11a.2 shows. Six 3×3 permutation matrices. The identity and the two cyclic arrangements, (x_2, x_3, x_1) and (x_3, x_1, x_2), are green: 0 or 2 inversions, sign $+1$. The three arrangements that exchange two labels are orange: 1 or 3 inversions, sign -1. Each title's sign is the determinant of the panel's matrix.

In [6], every pair of lengths 1, 2 and 3.

```
COUNTS = {}  # p -> {+1: count, -1: count, 0: count}
mismatches = 0  # pairs where gkd and the determinant differ
for p in (1, 2, 3):
    counts = {1: 0, -1: 0, 0: 0}
    for lower in itertools.product(range(8), repeat=p):  # all 8^p lower lists
        for upper in itertools.product(range(8), repeat=p):  # all 8^p upper lists
            value = gkd(lower, upper)
            if value != kdelta(lower, upper):
                mismatches += 1
            counts[value] += 1
    COUNTS[p] = counts
```

`itertools.product(range(8), repeat=p)` produces all 8^p lists of length p with entries 0 to 7. For each length the two nested loops visit all $8^p \cdot 8^p$ pairs, compute the rule, compare it with the literal determinant (counting any disagreement in `mismatches`; `+= 1` adds one) and count how often each value occurs. The counts of each length are stored in `COUNTS`.

```
    say(f"p = {p}: {8 ** (2 * p):6d} pairs; value +1: {counts[1]:4d} times, "
        f"-1: {counts[-1]:4d} times, 0: {counts[0]:6d} times")
```

Inside the loop over `p`, one line per length; `**` is a power, and `:6d` writes a whole number right-aligned in 6 places. Output: 64, 4096 and 262144 pairs, with the counts 8, 0, 56; 56, 56, 3984; and 1008, 1008, 260128, exactly the table of Section 11.4.

```
compared = sum(8 ** (2 * p) for p in (1, 2, 3))
report("pairs compared (all pairs of lengths 1, 2 and 3)", compared)
report("pairs where GKD and the determinant differ", mismatches)
report("different 0/1 matrices whose determinant sympy computed", len(DETERMINANTS))
```

Three RESULT lines: $64 + 4096 + 262144 = 266304$ pairs compared, 0 disagreements, and 145 different 0/1 matrices for which sympy had to compute a determinant; all other pairs reused a stored one.

```
wolfram_record = json.loads(repository_file(
    "Revision/gkd_lovelock/results/wolfram-gkd-report.json").read_text(
        encoding="utf-8"))
entries = [c for c in wolfram_record["checks"]
           if c["name"].startswith("gkd_equals_kdelta_exhaustive_length_")]
```

The Revision's Wolfram report is read: `read_text` reads the file as text and `json.loads` turns the JSON text into Python lists and dictionaries. Its checks form a list of entries; the comprehension keeps the entries whose names begin with `gkd_equals_kdelta_exhaustive_length_` (`startswith` tests how a text begins). There are three of them, for the lengths 1, 2 and 3; in each, the Revision's Wolfram verification compared the values of the Rust function GKD (written out by a small Rust program that calls it) with the author's literal determinant, evaluated by Wolfram, on every pair of lists of that length.

```
recorded_pairs = sum(int(re.search(r"all (\d+) pairs", e["detail"]).group(1))
                     for e in entries)  # the numbers of pairs the record names
```

Each entry's `detail` text names its number of pairs, as in "all 4096 pairs of index lists of length 2". The regular expression `all (\d+) pairs` finds this phrase (`\d+` is one or more digits, and the brackets mark the part to keep), `.group(1)` is the kept text and `int` turns it into a whole number; `sum` adds the three numbers: $64 + 4096 + 262144$.

```
check(mismatches == 0 and compared == 266304 and len(entries) == 3
      and all(e["verdict"] == "PASS" and "(0 mismatches;" in e["detail"]
              for e in entries) and recorded_pairs == 266304,
      "GKD equals the literal determinant for all 266304 pairs of lengths 1 to 3",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, checks "
             "gkd_equals_kdelta_exhaustive_length_1 to _3")
```

The check requires no disagreement among the notebook's own 266,304 pairs, and that the record's three checks are there, have the verdict PASS, report 0 mismatches and together speak of the same 266,304 pairs (`in` tests whether one text occurs inside another). Sixth PASS line. (The Revision's sympy report `python-lovelock-report.json` also has a check on these 266,304 pairs, `gkd_literal_equals_cofactor_expansion`, but it compares something else: the literal determinant with a second, independent way of computing a determinant, the cofactor expansion (Laplace's rule, proved in Section 11.13: the determinant is the sum of the entries of one row, each times the smaller determinant left when its row and column are removed, with alternating signs). It confirms the determinant side, not GKD, and is therefore not the record of this check; In [16] only confirms that it is there and passed.)

In [7], the counts against the formula and the Wolfram record.

```
def nonzero_pairs(p, n=8):
    return math.perm(n, p) * math.factorial(p)

def formula_counts(p):
    nonzero = nonzero_pairs(p)
    plus = nonzero if p == 1 else nonzero // 2  # p = 1: only the identity
    return {1: plus, -1: nonzero - plus, 0: 8 ** (2 * p) - nonzero}
```

`nonzero_pairs` is the formula $N_{\neq 0}(p) = 8!/(8-p)! \cdot p!$ of Section 11.4 (`n=8` gives the argument `n` the default value 8). `formula_counts` splits it: for $p = 1$ every nonzero value is $+1$, otherwise half of them (`//` is whole-number division); the zeros are the rest of the 8^{2p} pairs.

```
wolfram = json.loads(repository_file(
    "Revision/gkd_lovelock/results/wolfram-gkd-report.json").read_text(
        encoding="utf-8"))
for p in (1, 2, 3):
    recorded = [m for m in wolfram["measurements"]["gkdComparison"] if m["p"] == p][0]
    plus, minus, zero = recorded["plusOne"], recorded["minusOne"], recorded["zero"]
    say(f"p = {p}: formula {formula_counts(p)}, Wolfram record +1: {plus}, "
        f"-1: {minus}, 0: {zero}")
```

The Revision's Wolfram report is read; for each length the entry of its table `gkdComparison` with that `p` is found, its three counts are taken out, and the formula and the record are printed side by side (three output lines, the third broken by `say`).

```
check(all(COUNTS[p] == formula_counts(p) for p in (1, 2, 3)),
      "the counts of +1, -1 and 0 equal the formula for p = 1, 2, 3")
check(all(COUNTS[p] == {1: m["plusOne"], -1: m["minusOne"], 0: m["zero"]}
          for p in (1, 2, 3)
          for m in wolfram["measurements"]["gkdComparison"] if m["p"] == p),
      "the counts equal those of the Wolfram verification",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, measurements "
             "gkdComparison, p = 1, 2, 3")
```

Two checks: the measured counts equal the formula, and they equal the record's counts (two dictionaries are equal when they have the same keys with the same values). PASS lines seven and eight.

In [8], the map of all pairs of length 2 (Figure 11a.3).

```
pairs_of_labels = list(itertools.product(range(8), repeat=2))  # 64 lists (l1, l2)
grid = np.array([[gkd(lower, upper) for upper in pairs_of_labels]
                 for lower in pairs_of_labels])  # 64 x 64 values
```

The 64 lists of length 2 in the order $(0,0),(0,1),\ldots,(7,7)$, so the list (l_1, l_2) has the number $8l_1 + l_2$. `grid` holds the value of GKD for every pair: row = lower list, column = upper list.

```
fig, ax = plt.subplots(figsize=(6.6, 6.0))
picture = ax.imshow(grid, cmap="bwr", vmin=-1, vmax=1)  # blue -1, red +1
ticks = range(0, 64, 8)  # one tick at the start of each block of 8
ax.set_xticks(ticks, [f"({NAMES[t // 8]},x1)" for t in ticks], rotation=90)
ax.set_yticks(ticks, [f"({NAMES[t // 8]},x1)" for t in ticks])
```

The values are drawn with the colour map `bwr` (blue, white, red) from -1 (blue) through 0 (white) to $+1$ (red). `range(0, 64, 8)` is $0, 8, 16, \ldots, 56$, the first list of each block of eight; `t // 8` is the first label of that block, so the marks read (x_1, x_1), (x_2, x_1), and so on (rotated by 90 degrees on the horizontal axis).

```
ax.set_xlabel("upper list $(u_1, u_2)$, numbered $8 u_1 + u_2$")
ax.set_ylabel("lower list $(l_1, l_2)$, numbered $8 l_1 + l_2$")
ax.set_title("GKD for all 4096 pairs of index lists of length 2")
ax.grid(False)
fig.colorbar(picture, ax=ax, ticks=[-1, 0, 1], shrink=0.8, label="value of GKD")
```

Axis titles (matplotlib draws text between dollar signs as mathematics), the title, no grid, and a colour bar beside the picture that shows which colour means which value.

```
save_figure(fig, "gkd_map_length_two",
            "The value of the generalized Kronecker delta for all 4096 pairs of "
            ...)
check(int((grid == 1).sum()) == 56 and int((grid == -1).sum()) == 56
      and np.array_equal(grid, grid.T),
      "length 2: 56 values +1, 56 values -1, and the picture is symmetric")
```

After saving, the check counts the entries equal to 1 and to -1 (`grid == 1` is an array of true and false, and `.sum()` counts the trues) and tests that the picture equals its mirror image across the diagonal (`grid.T` is the transpose). The symmetry holds because the pair (lower, upper) and the pair (upper, lower) have transposed matrices and therefore the same determinant. Ninth PASS line.

What Figure 11a.3 shows. A 64×64 picture, almost all white. Red squares lie on the diagonal (upper list equal to the lower list, $+1$) except at the 8 lists with two equal labels, which are white. Blue squares lie at the mirrored places, where the upper list is the lower one reversed (-1). There are 56 of each; the remaining 3984 values are 0.

In [9], the value counts (Figure 11a.4).

```
fig, ax = plt.subplots(figsize=(7.4, 4.4))
width = 0.26  # the width of one bar
for shift, value, colour, name in ((-width, 1, "tab:red", "value +1"),
                                   (0.0, -1, "tab:blue", "value -1"),
                                   (width, 0, "0.6", "value 0")):
```

A bar chart with three bars per length: the loop runs over the three values, each with its sideways shift, its colour (`"0.6"` is a grey) and its name in the legend.

```
    heights = [COUNTS[p][value] if p < 4 else formula_counts(4)[value]
               for p in (1, 2, 3, 4)]
    bars = ax.bar([p + shift for p in (1, 2, 3, 4)], heights, width, color=colour,
                  label=name, hatch=None)
    bars[3].set_hatch("//")  # p = 4: from the formula
```

The heights are the measured counts for $p = 1, 2, 3$ and the formula for $p = 4$. `ax.bar` draws the four bars of this value; the fourth bar (place 3, counted from 0) gets a hatching to mark that it comes from the formula.

```
    for p, height in zip((1, 2, 3, 4), heights):
        ax.text(p + shift, max(height, 1.2) * 1.15, f"{height:,}" if height else
                "none", ha="center", va="bottom", fontsize=7, rotation=90)
```

Each bar gets its count written above it (the format `:,` puts commas between groups of three digits); a count of 0 cannot be drawn on a logarithmic axis, so it is written as "none" just above the bottom.

```
ax.set_yscale("log")  # a logarithmic vertical axis
ax.set_ylim(1.0, 2e9)
ax.set_xticks([1, 2, 3, 4], ["p = 1", "p = 2", "p = 3", "p = 4 (formula)"])
ax.set_xlabel("length $p$ of the two index lists")
ax.set_ylabel("number of pairs (logarithmic scale)")
ax.set_title("How often GKD is +1, -1 and 0 among all $8^{2p}$ pairs")
ax.legend(loc="upper left")
```

On a **logarithmic axis** each equal step is a factor of 10, so the counts 8 and 16,736,896 fit into one picture. The axis runs from 1 to 2×10^9; the remaining lines set the marks, titles and legend.

```
save_figure(fig, "value_counts",
            "The number of pairs of index lists of length $p$ over the eight labels "
            ...)
check(formula_counts(4) == {1: 20160, -1: 20160, 0: 16736896},
      "length 4: 20160 values +1, 20160 values -1 and 16736896 zeros (formula)")
```

The figure is saved and the formula's counts for $p = 4$ are checked: $1680 \cdot 24 = 40320$ nonzero values, half of each sign. Tenth PASS line.

What Figure 11a.4 shows. For each length three bars: red (+1), blue (−1), grey (0), on a logarithmic axis. Red and blue have equal height for $p \geq 2$; for $p = 1$ there is no −1. The grey bar grows much faster than the others: the fraction of nonzero values falls from 8 in 64 at $p = 1$ to 40,320 in 16,777,216 at $p = 4$, about one in 416.

In [10], random pairs of lengths 4 to 9.

```
rng = np.random.default_rng(12345)  # pseudo-random numbers with a fixed seed
SAMPLES = 2000  # pairs per length p
python_nonzero = {}  # p -> number of nonzero values among the samples
random_mismatches = 0
```

`np.random.default_rng(12345)` makes a generator of pseudo-random numbers that starts from the seed 12345, so every run on every computer draws the same numbers. 2,000 pairs are drawn for each length.

```
for p in range(4, 10):
    nonzero = 0
    for s in range(SAMPLES):
        upper = [int(v) for v in rng.integers(0, 8, size=p)]  # p labels from 0..7
        if s % 2 == 0:  # even s: the lower list is the upper list rearranged
            lower = [upper[i] for i in rng.permutation(p)]
        else:  # odd s: an independent random lower list
            lower = [int(v) for v in rng.integers(0, 8, size=p)]
```

`range(4, 10)` is 4 to 9. `rng.integers(0, 8, size=p)` draws p whole numbers from 0 to 7 (the upper bound 8 is not included). For an even sample number `s`, `rng.permutation(p)` is a random arrangement of the places $0, \ldots, p-1$, and the lower list takes the upper labels in that order: a rearranged pair. For an odd `s` the lower list is drawn independently.

```
        value = gkd(lower, upper)
        nonzero += value != 0  # True counts as 1, False as 0
        random_mismatches += value != kdelta(lower, upper)
    python_nonzero[p] = nonzero
    say(f"p = {p}: {SAMPLES} random pairs, {nonzero:4d} nonzero values")
```

For every sample the rule is computed, the nonzero values are counted, and every disagreement with the literal determinant is counted (a true comparison adds 1, a false one 0). One line per length is printed: 394, 186, 82, 24, 3 and 0 nonzero values for $p = 4$ to 9.

```
report("random pairs compared (lengths 4 to 9)", 6 * SAMPLES)
report("random pairs where GKD and the determinant differ", random_mismatches)
report("different 0/1 matrices whose determinant sympy computed (so far)",
       len(DETERMINANTS))
check(random_mismatches == 0,
      "GKD equals the literal determinant for 12000 random pairs of lengths 4 to 9")
check(python_nonzero[9] == 0,
      "every delta with 9 indices in 8 dimensions is 0 (pigeonhole)",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "check gkd_nine_indices_in_eight_dimensions_vanish")
```

RESULT lines: 12,000 pairs compared, 0 disagreements, and 10,097 different matrices met so far (this is why the cell takes a few seconds: sympy computes almost ten thousand new determinants of sizes 4 to 9). The two checks: no disagreement, and no nonzero value of length 9, as the pigeonhole principle demands (PASS lines eleven and twelve).

In [11], the counts against the birthday formula.

```
def all_different(p, n=8):
    return math.perm(n, p) / n ** p if p <= n else 0.0

def expected_nonzero(p, half):
    r = all_different(p)
    q = nonzero_pairs(p) / 8 ** (2 * p) if p <= 8 else 0.0
    mean = half * (r + q)
    spread = math.sqrt(half * r * (1 - r) + half * q * (1 - q))
    return mean, spread
```

`all_different` is the chance $r_p = 8!/((8-p)!\,8^p)$ of Section 11.4; for more than 8 labels it returns 0. `expected_nonzero` returns the expectation $N(r_p + q_p)$ and the standard deviation $\sqrt{Nr_p(1-r_p) + Nq_p(1-q_p)}$ for `half` $= N$ rearranged and N independent samples (`math.sqrt` is the square root).

```
within = True
for p in range(4, 10):
    mean, spread = expected_nonzero(p, SAMPLES // 2)
    distance = abs(python_nonzero[p] - mean) / spread if spread > 0 else 0.0
    say(f"p = {p}: counted {python_nonzero[p]:4d}, expected {mean:7.1f} "
```

```
        f"+- {spread:5.1f}  ({distance:.2f} standard deviations away)")
    within = within and (distance < 5.0 if spread > 0 else python_nonzero[p] == 0)
check(within, "the Python counts of nonzero values agree with the birthday formula")
```

For each length, with $N = 1000$, the distance of the count from its expectation is measured in standard deviations (`abs` is the size of a number; the format `:7.1f` writes a decimal number with one digit after the point). The output: 394 against 412.6 ± 15.6 (1.19 standard deviations), 186 against 205.8 ± 12.8 (1.55), 82 against 77.1 ± 8.4 (0.58), 24 against 19.3 ± 4.3 (1.09), 3 against 2.4 ± 1.6 (0.38), and 0 against exactly 0 for $p = 9$. The check requires every distance to be below 5 standard deviations (a chance of less than one in a million for each count), and exactly 0 where the standard deviation is 0. Thirteenth PASS line.

In [12], the cost of the determinant (Figure 11a.5).

```
lengths = list(range(1, 10))
leibniz_terms = [math.factorial(p) for p in lengths]  # products in the formula
comparisons = [p * (p - 1) // 2 for p in lengths]  # comparisons of the rule
all_pairs = [8 ** (2 * p) for p in lengths]  # all pairs of lists of length p
for p, terms, compare, total in zip(lengths, leibniz_terms, comparisons, all_pairs):
    say(f"p = {p}: Leibniz products {terms:6d}, comparisons of GKD {compare:2d}, "
        f"pairs of lists {total:.3e}")
```

The three rows of the cost table of Section 11.4 for $p = 1$ to 9, printed one line per length (the format `:.3e` writes a number in the form 1.678×10^7 as `1.678e+07`).

```
fig, ax = plt.subplots(figsize=(7.4, 4.4))
ax.semilogy(lengths, leibniz_terms, "o-", label="products in the Leibniz formula, $p!$")
ax.semilogy(lengths, [max(c, 0.5) for c in comparisons], "s-",
            label="comparisons made by GKD, $p(p-1)/2$")
ax.semilogy(lengths, all_pairs, "^:", label="all pairs of index lists, $8^{2p}$")
```

`ax.semilogy` draws a curve with a logarithmic vertical axis; `"o-"` means circles joined by a line, `"s-"` squares and a line, `"^:"` triangles and a dotted line. The comparison count 0 of $p = 1$ is drawn at 0.5, because 0 has no place on a logarithmic axis.

```
ax.axvline(4.5, color="0.5", lw=0.8)  # where exhaustive testing ends
ax.text(4.65, 3e15, "right of this line:\nrandom samples only", fontsize=8,
        va="top")
ax.set_xlabel("length $p$ of the index lists")
ax.set_ylabel("count (logarithmic scale)")
ax.set_title("The work of the literal determinant and of the rule GKD")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "cost_of_the_determinant",
            "Work per evaluation of the generalized Kronecker delta for index lists "
            ...)
```

A thin vertical line at $p = 4.5$ separates the lengths tested exhaustively from those tested by samples, with a note beside it (`\n` starts a new line of text); then titles, legend, and the saved figure.

```
timing_rng = np.random.default_rng(7)
timing_pairs = []
for _ in range(200):
    upper = [int(v) for v in timing_rng.permutation(8)[:7]]  # 7 different labels
    lower = [upper[i] for i in timing_rng.permutation(7)]  # the same, rearranged
    timing_pairs.append((lower, upper))
```

200 pairs of length 7 for the timing, from a second generator with the seed 7: the first 7 entries (`[:7]`) of a random arrangement of the eight labels are 7 different labels, and the lower list is the same labels in another random order. Every one of these pairs has a nonzero value.

```
start = time.perf_counter()
rule_values = [gkd(lower, upper) for lower, upper in timing_pairs]
rule_seconds = time.perf_counter() - start
start = time.perf_counter()
determinant_values = [int(sp.Matrix(outer_delta(lower, upper)).det())
                      for lower, upper in timing_pairs]  # no memory: all computed
determinant_seconds = time.perf_counter() - start
```

`time.perf_counter()` reads a stopwatch; the difference of two readings is the time between them in seconds. The rule is timed on the 200 pairs, then sympy's exact determinant on the same pairs, computed afresh each time (without the memory of `kdelta`).

```
check(rule_values == determinant_values,
      "200 pairs of length 7: the rule and sympy's determinant agree")
check(determinant_seconds > 10 * rule_seconds,
      "the rule GKD is more than ten times faster than the determinant (p = 7)")
```

Two checks: the 200 values agree, and the determinants took more than ten times as long as the rule. The times themselves are never printed, so the output stays the same on every run. PASS lines fourteen and fifteen.

What Figure 11a.5 shows. Three curves on a logarithmic axis against the length p. The circles ($p!$) rise ever more steeply, to 362,880 at $p = 9$; the squares ($p(p-1)/2$) stay small, 36 at $p = 9$; the triangles (8^{2p}) rise as a straight line, because a power 64^p is a straight line on a logarithmic axis, to 1.8×10^{16}. Right of the line at $p = 4.5$ only samples can be tested.

In [13], the Rust program is built, and the command of its self-test.

```
program = rust_program("Revision/gkd_lovelock/code/Cargo.toml", "lovelock_gkd")
```

The helper of the set-up cell runs cargo for the crate `Revision/gkd_lovelock/code` and returns the path of the program `lovelock_gkd` (with `.exe` on Windows), named `program` here. When the program is up to date this takes about a second; a first build took a few seconds on the computer that built the book (the crate has no dependencies, so nothing is downloaded). Output: Rust program lovelock_gkd is built and ready.

```
COMMAND = ["lovelock_gkd", "gkd-selftest", "--exhaustive-max", "4", "--output", "FOLDER"]
say("To repeat the self-test (7 to 13 minutes), run in the folder of the program: "
    + " ".join(COMMAND))
```

`COMMAND` is the list of the words of the command that runs the self-test: the program, the command `gkd-selftest`, the option that makes the lengths 1 to 4 exhaustive, and the folder for the result file; `" ".join(COMMAND)` joins the words with spaces. The cell does not run the command. The self-test takes 7 to 13 minutes on the computer that built the book, most of it in the 200,000 literal determinants of 9×9 matrices, each a sum of $9! = 362880$ products; that is longer than the limit of 7 minutes that this book sets for one computation. Output: the line with the command

```
lovelock_gkd gkd-selftest --exhaustive-max 4 --output FOLDER
```

To repeat the self-test yourself, run this command in a terminal, in the folder `Revision/gkd_lovelock/code/target/release` (on Windows the program file is `lovelock_gkd.exe`), with a folder of your choice in place of FOLDER: the file `gkd-selftest.json` that it writes there must equal the record byte for byte.

In [14], the record of the Rust self-test.

```
SELFTEST = "Revision/gkd_lovelock/results/gkd-selftest.json"
written = repository_file(SELFTEST).read_bytes()  # the record of the Rust run
selftest_record = json.loads(written.decode("utf-8"))
say("The record of the Rust self-test (as a table):")
```

`read_bytes()` reads the record as its raw bytes (the next cell uses them again), `decode("utf-8")` turns them into text and `json.loads` into a dictionary. Then a heading line is printed.

```
rust_rows = {}  # p -> (mode, pairs, nonzero or None, mismatches)
for row in selftest_record["results"]:
    rust_rows[row["p"]] = (row["mode"], row["pairs"], row.get("nonzero"),
                           row["mismatches"])
```

The entry `results` of the record holds one row per length p: the mode (`exhaustive` or `random`), the number of pairs, for the random lengths the number of nonzero values, and the number of disagreements between GKD and the literal determinant. `row.get("nonzero")` gives the number of nonzero values, and `None` for an exhaustive row, which has no such entry. The dictionary `rust_rows` keeps each row as a tuple under its length.

```
for p, (mode, pairs, nonzero, bad) in sorted(rust_rows.items()):
    extra = "" if nonzero is None else f", {nonzero:6d} nonzero"
    say(f"  p = {p}: {mode:10s} {pairs:9d} pairs{extra}; disagreements: {bad}")
```

The rows are printed in the order of p as a table. The output shows 64, 4096, 262144 and 16777216 pairs compared exhaustively for $p = 1$ to 4, and 200,000 random pairs for each $p = 5$ to 9 with 20538, 7812, 1949, 244 and 0 nonzero values; every disagreement count is 0.

```
check(selftest_record["program"] == "lovelock_gkd gkd-selftest"
      and selftest_record["verdict"] == "SUCCESS",
      "the record of the Rust program lovelock_gkd gkd-selftest has the verdict "
      "SUCCESS", record=SELFTEST)
```

```
check(sorted(rust_rows) == list(range(1, 10))
      and all(row[3] == 0 for row in rust_rows.values())
      and rust_rows[4][:2] == ("exhaustive", 16777216),
      "Rust: GKD equals the literal determinant for every tested pair, p = 1 to 9",
      record=SELFTEST)
check(program.is_file(), "the program lovelock_gkd that repeats the self-test is built")
```

The first check requires the program name of the record and its verdict SUCCESS. The second requires a row for every length 1 to 9, no disagreement in any row (`row[3]` is the fourth entry, the mismatches) and the exhaustive test of all 16,777,216 pairs of length 4 (`[:2]` takes the first two entries of the row). The third requires that the program file that repeats the self-test exists (`is_file()`). PASS lines sixteen to eighteen.

In [15], the self-test against the birthday formula (Figure 11a.6).

```
selftest = json.loads(written.decode("utf-8"))
rust_nonzero = {row["p"]: row["nonzero"] for row in selftest["results"]
                if row["mode"] == "random"}
```

The bytes just compared are decoded as text and read as JSON. A **dictionary comprehension** collects, for every random length, its number of nonzero values.

```
agree = True
for p, nonzero in sorted(rust_nonzero.items()):
    mean, spread = expected_nonzero(p, 100000)
    distance = abs(nonzero - mean) / spread if spread > 0 else 0.0
    say(f"Rust p = {p}: counted {nonzero:6d}, expected {mean:8.1f} +- {spread:6.1f}"
        f"  ({distance:.2f} standard deviations away)")
    agree = agree and (distance < 5.0 if spread > 0 else nonzero == 0)
check(selftest["verdict"] == "SUCCESS" and agree and rust_nonzero[9] == 0,
      "the Rust counts of nonzero values agree with the birthday formula")
```

The same comparison as in In [11], now with $N = 100000$ samples of each kind: 20538 against 20582.9 ± 128.0 (0.35 standard deviations), 7812 against 7711.6 ± 84.4 (1.19), 1949 against 1927.2 ± 43.5 (0.50), 244 against 240.9 ± 15.5 (0.20), and 0 for $p = 9$. The check also requires the verdict SUCCESS of the file. Nineteenth PASS line.

```
lengths_1_to_8 = np.arange(1, 9)  # r_p is drawn where it is not zero
fig, ax = plt.subplots(figsize=(7.4, 4.4))
ax.semilogy(lengths_1_to_8, [all_different(p) for p in lengths_1_to_8], "k-",
            label="chance that $p$ labels out of 8 are all different, $r_p$")
```

`np.arange(1, 9)` is the array $1, \ldots, 8$; the black line (`"k-"`) is r_p on a logarithmic axis.

```
python_points = [p for p in python_nonzero if python_nonzero[p] > 0]
ax.semilogy(python_points, [python_nonzero[p] / (SAMPLES // 2)
                            for p in python_points], "o",
            label="Python: nonzero values / 1000 rearranged pairs")
```

```
rust_points = [p for p in rust_nonzero if rust_nonzero[p] > 0]
ax.semilogy(rust_points, [rust_nonzero[p] / 100000 for p in rust_points], "s",
            fillstyle="none", markersize=10,
            label="Rust: nonzero values / 100000 rearranged pairs")
```

The measured fractions: the nonzero values of all the samples of one length divided by the number of rearranged samples, dots for Python and large open squares for Rust. Lengths with no nonzero value are left out, because 0 has no place on a logarithmic axis.

```
ax.plot([9], [1e-6], "v", color="black", markersize=9)  # marks the zeros of p = 9
ax.text(9.0, 2.2e-6, "p = 9: none\n(0 of 1000,\n0 of 100000)", fontsize=8,
        ha="center", va="bottom")
ax.axvline(8.5, color="0.5", lw=0.8)
ax.text(8.6, 0.3, "more than 8\nlabels: always\na repetition", fontsize=8, va="top")
```

A black triangle at the bottom edge and a note mark the zeros of $p = 9$; a vertical line at 8.5 with a note marks where every list must repeat a label.

```
ax.set_xlim(0.5, 10.0)
ax.set_ylim(5e-7, 2.0)
ax.set_xlabel("length $p$ of the index lists")
ax.set_ylabel("fraction (logarithmic scale)")
ax.set_title("Nonzero deltas among rearranged random pairs")
ax.legend(loc="lower left", fontsize=8)
save_figure(fig, "all_labels_different",
            "The chance $r_p = 8!/((8 - p)!\\, 8^p)$ that $p$ random labels out of "
            ...)
```

The ranges of the two axes, titles, legend and the saved figure (in the caption string a doubled backslash stands for one backslash).

What Figure 11a.6 shows. The chance r_p falls from 1 at $p = 1$ to 0.0024 at $p = 8$; the dots and squares lie on the line, within their random scatter. The independent samples add at most $q_4 = 40320/8^8 \approx 0.0024$, too little to see. For $p = 9$ both tests found no nonzero value, as the pigeonhole principle demands.

In [16], the quoted records once more.

```
def verdicts(path):
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    checks = data["checks"]
    if isinstance(checks, dict):  # name -> {"passed": true or false, ...}
        return {name: "PASS" if entry["passed"] else "FAIL"
                for name, entry in checks.items()}
    return {entry["name"]: entry["verdict"] for entry in checks}  # a list of entries
```

A helper (docstring left out) that returns, for one report, a dictionary from the name of each check to PASS or FAIL. The Revision reports store their checks in one of two forms, and `isinstance(checks, dict)` tells which: a dictionary of entries with a field `passed`, or a list of entries with a `name` and a `verdict`.

```
RECORDS = "Revision/gkd_lovelock/results"  # the folder of the Revision records
QUOTED = {  # report -> the checks that this notebook quotes from it
    "python-lovelock-report.json": [
        "gkd_examples", "gkd_literal_equals_cofactor_expansion",
        "gkd_nine_indices_in_eight_dimensions_vanish"],
    "wolfram-gkd-report.json": [
        "gkd_equals_kdelta_exhaustive_length_1",
        "gkd_equals_kdelta_exhaustive_length_2",
        "gkd_equals_kdelta_exhaustive_length_3"],
}
```

The checks that the notebook's text quotes, by report.

```
for report_name, names in QUOTED.items():
    found = verdicts(f"{RECORDS}/{report_name}")
    for name in names:
        say(f"{report_name}: {name} {found.get(name, 'MISSING')}")
    check(all(found.get(name) == "PASS" for name in names),
          f"the {len(names)} checks quoted from {report_name} are there and PASS",
          record=f"{RECORDS}/{report_name}, checks " + ", ".join(names))
```

For each report every quoted check is printed with its verdict (`get(name, 'MISSING')` gives MISSING for a name that is not there), and the check requires all of them to be present with PASS. `", ".join(names)` joins the names with commas. Two PASS lines, twenty and twenty-one.

```
provenance = repository_file(
    f"{RECORDS}/PROVENANCE_OF_THE_COMPUTATION.md").read_text(encoding="utf-8")
definition = ("[lower_, upper_] /; Length[lower] == Length[upper] := "
              "Det[Outer[delta, lower, upper]]")  # after the name of the delta
check(definition in provenance,
      "the record quotes the author's definition as section 4 of this notebook "
      "does",
      record=f"{RECORDS}/PROVENANCE_OF_THE_COMPUTATION.md")
```

The record of the author's definition is read, and the check requires the definition, from the bracket after its name on, to occur in it exactly as the notebook quotes it in its own section 4 (the name itself is written with a Greek letter in the record). Two strings written one after the other inside brackets are joined into one by Python. Twenty-second PASS line.

```
order_three = [row for row in json.loads(repository_file(
    f"{RECORDS}/lovelock-report.json").read_text(encoding="utf-8"))["counters"]
    if row["k"] == 3][0]
report("GKD calls of the order-3 Lovelock sum (record)", order_three["gkdCalls"])
check(order_three["gkdCalls"] == 495360,
      "the order-3 Lovelock sum calls GKD 495360 times, as section 4 of this "
      "notebook says",
      record=f"{RECORDS}/lovelock-report.json, counters, k = 3, gkdCalls")
```

The Rust report's counters are read and the row of order 3 is taken; its number of GKD calls, 495,360, is printed and checked (the number quoted in the notebook's section 4 and explained in Section 11.12). Twenty-third PASS line.

In [17], the end.

```
figure_files = [f"11a_{k}_{name}.png" for k, name in enumerate(
    ["outer_delta_matrices", "six_permutations", "gkd_map_length_two",
     "value_counts", "cost_of_the_determinant", "all_labels_different"], 1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_files),
      "all six figure files of the notebook exist")
all_checks_passed()
```

`enumerate(..., 1)` numbers the six figure names from 1, which gives the six file names; the check requires all six files to exist in the figures folder (PASS line twenty-four), and `all_checks_passed()` prints the last line, ALL 24 CHECKS PASSED (notebook 11a). The 24 checks are: 2 in In [2], 1 each in In [3], In [4], In [5], In [6], 2 in In [7], 1 each in In [8] and In [9], 2 in In [10], 1 in In [11], 2 in In [12], 3 in In [14], 1 in In [15], 4 in In [16] and 1 in In [17].

11.10 The curvature that the Lovelock sums need

The Lovelock tensors are built from the Riemann tensor. Chapter 3 computed it for the author's metric by hand; here we collect what the sums need, in the convention of every Revision record (the convention of Misner, Thorne and Wheeler, Section 3.17):

$$\Gamma^{a}{}_{bc} = \tfrac{1}{2}\, g^{aa}\big(\partial_b g_{ac} + \partial_c g_{ab} - \partial_a g_{bc}\big), \qquad R^{a}{}_{bcd} = \partial_c \Gamma^{a}{}_{db} - \partial_d \Gamma^{a}{}_{cb} + \sum_e \big(\Gamma^{a}{}_{ce}\Gamma^{e}{}_{db} - \Gamma^{a}{}_{de}\Gamma^{e}{}_{cb}\big),$$

and $R^{ab}{}_{cd} = g^{bb} R^{a}{}_{bcd}$ (no sum; for a diagonal metric the general $\sum_e g^{be} R^{a}{}_{ecd}$ keeps only $e = b$). The form $R^{ab}{}_{cd}$, with two labels up and two down, is the one the Lovelock sums use. It changes sign when the two upper labels or the two lower labels are exchanged:

$$R^{ab}{}_{cd} = -R^{ba}{}_{cd} = -R^{ab}{}_{dc}$$

(the Rust report `lovelock-report.json`, check `riemann_antisymmetry`; Section 3.17 proves it). In particular $R^{aa}{}_{cd} = 0$: a component with two equal upper labels or two equal lower labels vanishes.

The plane curvatures. For two different directions a and b, $K(a,b) = R^{ab}{}_{ab}$ (no sum) is the curvature of their coordinate plane. Section 3.24 computed all 28 planes by hand. With i standing for a 3-space direction (x_1, x_2, x_3), j for an extra time (x_5, x_6, x_7) and k for either:

plane	**how many**	$K(a,b)$	**at** $a_4' = 2H$, $a_4'' = 0$
two 3-space directions (i, i')	3	$a_4'^2 - H^2$	$3H^2$
two extra times (j, j')	3	$a_4'^2 - H^2$	$3H^2$
a 3-space direction and an extra time (i, j)	9	$-(a_4'^2 + H^2)$	$-5H^2$
a 3-space direction and the time (i, x_4)	3	$a_4'^2 + a_4''$	$4H^2$

plane	**how many**	$K(a,b)$	**at** $a_4' = 2H$**,** $a_4'' = 0$
an extra time and the time (j, x_4)	3	$a_4'^2 - a_4''$	$4H^2$
a transverse direction and the hidden one (k, x_0)	6	$-H^2$	$-H^2$
the time and the hidden direction (x_4, x_0)	1	0	0

Figure 11b.2 draws these 28 numbers as an 8×8 table at $a_4' = 2H$, once with $a_4'' = 0$ and once with $a_4'' = H^2$ (Notebook 11b, In [9]). Each plane with $K \neq 0$ gives four nonzero components, $R^{ab}{}_{ab} = R^{ba}{}_{ba} = K(a,b)$ and $R^{ab}{}_{ba} = R^{ba}{}_{ab} = -K(a,b)$: 27 planes, 108 components.

The components that mix the time and the hidden direction (PROVED). The other nonzero components connect the plane of x_4 and x_k with the plane of x_0 and x_k. We derive the first kind once more, line by line, writing the scale-factor exponent of the transverse direction k as σ_k: the metric entry is $g_{kk} = \epsilon_k\, e^{2\sigma_k a_4} \sin^{1/3} z$ with $\sigma_k = +1$, $\epsilon_k = +1$ for 3-space (inflating, space-like) and $\sigma_k = -1$, $\epsilon_k = -1$ for an extra time (deflating, time-like). The formula for $R^a{}_{bcd}$ with $a = x_4$, $b = k$, $c = x_0$, $d = k$ reads

$$R^4{}_{k0k} = \partial_0 \Gamma^4{}_{kk} - \partial_k \Gamma^4{}_{0k} + \sum_e \Gamma^4{}_{0e}\Gamma^e{}_{kk} - \sum_e \Gamma^4{}_{ke}\Gamma^e{}_{0k}$$

(the definition with these four labels). Nothing depends on x_k, so $\partial_k(\dots) = 0$; every symbol $\Gamma^4{}_{0e}$ is zero (the only nonzero symbols with the upper label x_4 are $\Gamma^4{}_{kk}$, Section 3.23); and in the last sum only $e = k$ survives:

$$R^4{}_{k0k} = \partial_0 \Gamma^4{}_{kk} - \Gamma^4{}_{kk}\,\Gamma^k{}_{0k}.$$

The two symbols are, by the Christoffel formula with $g^{44} = -1$,

$$\Gamma^4{}_{kk} = -\tfrac{1}{2}\, g^{44}\, \partial_4 g_{kk} = \tfrac{1}{2}\, \epsilon_k\, 2\sigma_k a_4'\, e^{2\sigma_k a_4} \sin^{1/3} z = \epsilon_k \sigma_k\, a_4'\, e^{2\sigma_k a_4} \sin^{1/3} z,$$

$$\Gamma^k{}_{0k} = \tfrac{1}{2}\, g^{kk}\, \partial_0 g_{kk} = H \cot z$$

(the chain rule: $\partial_4 e^{2\sigma_k a_4} = 2\sigma_k a_4' e^{2\sigma_k a_4}$; and $\partial_0 \ln \sin^{1/3} z = \tfrac{1}{3} \cot z \cdot 6H = 2H \cot z$, half of which is $H \cot z$). Since $\partial_0 \sin^{1/3} z = 2H \cot z \, \sin^{1/3} z$,

$$R^4{}_{k0k} = \epsilon_k \sigma_k\, a_4'\, e^{2\sigma_k a_4} \sin^{1/3} z\, (2H \cot z - H \cot z) = \epsilon_k \sigma_k\, H a_4' \cot z\, e^{2\sigma_k a_4} \sin^{1/3} z$$

(the derivative of the product; then the common factor taken out). Raising the second label multiplies by $g^{kk} = 1/(\epsilon_k e^{2\sigma_k a_4} \sin^{1/3} z)$:

$$R^{4k}{}_{0k} = \sigma_k\, H a_4' \cot z$$

($\epsilon_k/\epsilon_k = 1$ and the exponentials cancel). So the sign is set by σ_k alone, that is by whether the direction inflates or deflates, not by whether it is space-like or time-like: $R^{4i}{}_{0i} = +Ha_4' \cot z$ for the three 3-space directions and $R^{4j}{}_{0j} = -Ha_4' \cot z$ for the three extra times, as Section 3.24 found. The same steps with $a = x_0$, $c = x_4$ give $R^{0i}{}_{4i} = -Ha_4' \tan z$ and $R^{0j}{}_{4j} = +Ha_4' \tan z$ (Section 3.24). With the antisymmetries each of the six transverse k gives eight such components: 48. Together $108 + 48 = 156$ nonzero components of the 4096 (record check `riemann_antisymmetry`, "156 nonzero entries"; Notebook 11b, In [7], recomputes them; Figure 11b.3 draws all 4096 at one point).

What this means for the Ricci tensor. The off-diagonal Ricci component $R^{x_4}{}_{x_0} = \sum_c R^{x_4 c}{}_{x_0 c}$ is the sum of the seven terms $c = x_1, \ldots, x_7$ (the term $c = x_0$ vanishes by antisymmetry):

$$R^{x_4}{}_{x_0} = 3 \cdot (+Ha_4' \cot z) + 0 + 3 \cdot (-Ha_4' \cot z) = 0$$

(three inflating directions, the time itself, three deflating directions). On the background $b_4 = 1$ the cancellation is exact for every a_4, because there are as many inflating as deflating directions (Notebook 11b, In [11], Figure 11b.4). Section 11.21 shows that the same cancellation leaves all three Lovelock tensors without an x_4-x_0 component.

With the second function b_4 (PROVED by exact computation). The Revision records compute the curvature for the author's metric of 2026-10-14, whose extra-time components carry the second function $b_4(x_4)$: $g_{jj} = -e^{-2a_4} b_4 \sin^{1/3} z$. The table and the components above are its background $b_4 = 1$ (and every constant b_4, which is a rescaling of the extra times). With a changing b_4 the same 156 components are nonzero, but those with an extra time contain b_4'/b_4 and b_4''/b_4 as well, and the three extra-time terms of $R^{x_4}{}_{x_0}$ no longer cancel the three space terms:

$$R^{x_4}{}_{x_0} = \frac{3}{2} H \cot z \frac{b_4'}{b_4}, \qquad R = 6a_4'^2 - 42H^2 + 3\frac{b_4''}{b_4} - 3a_4'\frac{b_4'}{b_4}$$

(record `curvature.json`, entries `einsteinMixed` and `ricciScalar`; Notebook 11b, In [8] and In [11], recomputes both with sympy). So with a changing b_4 the time and the hidden direction mix; Chapter 12 shows what this does to the field equations.

Three facts used below (PROVED, on the background $b_4 = 1$).

- Every nonzero $R^{ab}{}_{cd}$ is one of $a_4'^2 - H^2$, $-(a_4'^2 + H^2)$, $a_4'^2 \pm a_4''$, $-H^2$, $\pm Ha_4' \cot z$, $\pm Ha_4' \tan z$: a polynomial in H, a_4', a_4'', $\cot z$ and $\tan z = 1/\cot z$, free of e^{a_4} and of $\sin^{1/3} z$ (record check `mixed_riemann_free_of_sin_third`; `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `mixed_riemann_free_of_warp_and_exponential`; Notebook 11b, In [7]).
- **Weight 2.** Count H and a_4' as 1 and a_4'' as 2 (each is one inverse length per count: $z = 6Hx_0$ is a pure number, so H is an inverse length; a_4 is a pure number, so $a_4' = da_4/dx_4$ is an inverse length and a_4'' an inverse length squared), and $\cot z$ as 0. Then every one of the components just listed has the weight 2: curvature has the dimension $1/\text{length}^2$.
- **The Ricci tensor, the Ricci scalar and the Einstein tensor** (Section 3.25): $R^i{}_i = a_4'' - 6H^2$, $R^4{}_4 = 6a_4'^2$, $R^j{}_j = -a_4'' - 6H^2$, $R^0{}_0 = -6H^2$, every off-diagonal entry zero; $R = 6a_4'^2 - 42H^2$; and

$$G^{i}{}_{i} = -3a_4'^2 + a_4'' + 15H^2, \quad G^{4}{}_{4} = 3a_4'^2 + 21H^2, \quad G^{j}{}_{j} = -3a_4'^2 - a_4'' + 15H^2, \quad G^{0}{}_{0} = 15H^2 - 3a_4'^2$$

(record `curvature.json`, its entries for the Ricci tensor, the Ricci scalar and the Einstein tensor; Notebook 11b, In [8], reproduces the Ricci scalar).

11.11 Lovelock's equation (4.38): the three Lovelock tensors

The formula. The author's notebook contains, as the cell stored in the file as In[101] (his In[68]), an image of equation (4.38) of the book of Lovelock and Rund; the Revision rendered it to `Revision/gkd_lovelock/results/notebook-in68-image.png` and read the formula from that picture (record `Revision/gkd_lovelock/results/PROVENANCE_OF_THE_COMPUTATION.md`). For a space of $n = 2m$ dimensions it reads, as programmed in the record (`Revision/gkd_lovelock/code/src/lovelock.rs`),

$$A^{lh} = \sqrt{|\det g|} \sum_{k=1}^{m-1} \alpha_{(k)}\, g^{jl}\, \delta^{h\, h_1 \ldots h_{2k}}_{j\, j_1 \ldots j_{2k}}\, R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}} + \lambda \sqrt{|\det g|}\, g^{lh},$$

with constants $\alpha_{(k)}$ and λ, and a sum over every label that appears once up and once down (j and the $4k$ labels $h_1, \ldots, h_{2k}, j_1, \ldots, j_{2k}$). The building blocks are, for each **order** k, the **Lovelock tensor**

$$P_{(k)}{}^{h}{}_{j} = \sum \delta^{h\, h_1 \ldots h_{2k}}_{j\, j_1 \ldots j_{2k}}\, R^{j_1 j_2}{}_{h_1 h_2}\, R^{j_3 j_4}{}_{h_3 h_4} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}$$

(the sum over the $4k$ labels $h_1, \ldots, h_{2k}, j_1, \ldots, j_{2k}$; h and j are free), the **Lovelock scalar**, the same sum without the free pair,

$$L_{(k)} = \sum \delta^{h_1 \ldots h_{2k}}_{j_1 \ldots j_{2k}}\, R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}},$$

and the **density** $A_{(k)}{}^{lh} = \sqrt{|\det g|}\, g^{ll}\, P_{(k)}{}^{h}{}_{l}$ (no sum; diagonal metric). Read the generalized delta carefully: its upper list $(h, h_1, \ldots, h_{2k})$ collects the LOWER labels of the curvature factors, and its lower list $(j, j_1, \ldots, j_{2k})$ their UPPER labels. In the language of GKD,

$$P_{(k)}{}^{h}{}_{j} = \sum \mathrm{GKD}([j, j_1, \ldots, j_{2k}],\, [h, h_1, \ldots, h_{2k}]) \prod_{i=1}^{k} R^{j_{2i-1} j_{2i}}{}_{h_{2i-1} h_{2i}},$$

the lower list first, as in the author's `kδ[lower, upper]`. The matrix of the exchanged lists, with the entries $\delta(u_i, l_j)$, is the transpose of M, and a matrix and its transpose have the same determinant (rule 2 of Section 1.20); so exchanging the two lists does not change the value. The record of the field equations writes them in the other order (`Revision/field_equations_a4/a4-equations.json`, key `conventions`, entry `lovelock`).

Which orders exist (PROVED). The delta of order k has $2k + 1$ labels in each list. In eight dimensions ($m = 4$) the sum runs over $k = 1, 2, 3$, and the order $k = 4$, with nine labels, vanishes

identically by the pigeonhole principle (Section 11.4; record check `k4_tensor_vanishes`). So there are exactly three Lovelock tensors in eight dimensions. The scalar $L_{(4)}$, with eight labels per list, does not vanish: it is the **Euler density** of eight dimensions, and only its tensor $P_{(4)}$ is zero. The name comes from a classical theorem that this book quotes and does not prove (ASSUMED): in a space of even dimension $n = 2m$ the Lovelock scalar of order m is called the Euler density, because for a **closed** space (finite and without an edge, like the surface of a ball) with a positive-definite metric (every squared length positive, unlike the author's metric) its integral over the whole space, with the volume factor $\sqrt{|\det g|}$, is a constant times the **Euler characteristic**: a whole number that depends only on the shape of the space (2 for the surface of a ball, 0 for the surface of a ring) and does not change when the metric is deformed (the Chern-Gauss-Bonnet theorem). A quantity whose integral does not change when the metric changes gives no field equation; this agrees with $P_{(4)} = 0$, which the pigeonhole principle proved above for every metric. For the author's metric the program prints it (Notebook 11b, In [3]):

$$L_{(4)} = -663552\, H^2 a_4'^6 - 442368\, H^4 a_4'^4 - 663552\, H^6 a_4'^2.$$

The usual normalisation. Books on gravity use the normalised tensors

$$E_{(k)}{}^h{}_j = -\frac{1}{2^{k+1}}\, P_{(k)}{}^h{}_j,$$

because then $E_{(1)}$ is exactly Einstein's tensor G (Section 11.14). The field equations of Chapter 12 are $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda \delta^\mu_\nu = \kappa T^\mu{}_\nu$, with $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$ for Einstein's gravity (record `Revision/field_equations_a4/a4-equations.json`, key `conventions`, entry `fieldEquations`). Any other normalisation is absorbed into the constants α_k.

What Lovelock proved (quoted, ASSUMED in general). For every metric each $P_{(k)}$ has zero covariant divergence, $\sum_h \nabla_h P_{(k)}{}^h{}_j = 0$, and is symmetric once its upper label is lowered, $g_{hh} P_{(k)}{}^h{}_j = g_{jj} P_{(k)}{}^j{}_h$ (for a diagonal metric); and every tensor with these properties that is built from the metric and its first and second derivatives is a combination of the $P_{(k)}$ and of δ^h_j. We do not prove this theorem. For the author's metric both properties are PROVED by exact computation in the record: checks `k1_divergence_free` to `k3_divergence_free` and `k1_symmetric` to `k3_symmetric` of `Revision/gkd_lovelock/results/lovelock-report.json` and of `Revision/gkd_lovelock/results/python-lovelock-report.json` (the symmetry makes $A_{(k)}{}^{lh} = A_{(k)}{}^{hl}$). Section 11.22 writes out what zero divergence means for the components.

Weight $2k$ (PROVED). The generalized delta is a pure number, and each of the k curvature factors has the weight 2 (Section 11.10). So every term of $P_{(k)}$ has the weight $2k$: the tensor of order k has the dimension $1/\text{length}^{2k}$. The three orders can be added in one equation only with constants α_k of different dimensions, for example $\alpha_k = w_k / H^{2k-2}$ with pure numbers w_k; this is the role of H as "a fundamental inverse length" in the author's notebook (Chapter 12 uses the combinations $\alpha_2 H^2$ and $\alpha_3 H^4$).

11.12 Organising the sum: only nonzero curvature, no repeated label

How large the literal sum is. For one component (h, j) the sum over the $4k$ labels $h_1, \ldots, h_{2k}, j_1, \ldots, j_{2k}$, each with 8 values, has 8^{4k} terms; for all 64 components $64 \cdot 8^{4k}$. That

is 2.6×10^5 terms for $k = 1$, 1.1×10^9 for $k = 2$, 4.4×10^{12} for $k = 3$ and 1.8×10^{16} for $k = 4$ (Notebook 11b, In [5]). Each term is a product of exact polynomials, so the literal sum of order 3 is out of reach. Three exact facts make it small.

Step 1: only nonzero curvature factors. A term with a vanishing curvature factor vanishes. So each factor need only run through the 156 nonzero entries $R^{ab}{}_{cd}$ of Section 11.10, and a term is an ordered choice of k entries: $64 \cdot 156^k$ terms for all components, 1.0×10^4, 1.6×10^6, 2.4×10^8 and 3.8×10^{10} for $k = 1$ to 4.

Step 2: no repeated label. If two chosen entries share an upper label, or an entry shares an upper label with the free label j, the delta's lower list repeats a label and the delta is 0 (case a of Section 11.3); the same for the lower labels and the free h (case b). The program therefore builds the choices one entry at a time and keeps an entry only if it repeats no label already used. To test this quickly it stores a set of labels as a **bit mask**, the whole number $\sum 2^{\text{label}}$: the set $\{x_1, x_3\}$ (numbers 0 and 2) is $2^0 + 2^2 = 5$. Two sets share a label exactly when the bitwise AND of their masks is not 0 (the AND keeps a bit where both numbers have a 1, Section 1.49), and the union of two sets is their bitwise OR (a bit is 1 where at least one of the two numbers has a 1). A complete choice of k entries is called a **leaf**. The counts of leaves for all 64 components are 5,616, 176,640, 1,128,960 and 0 for $k = 1, 2, 3, 4$ (record `Revision/gkd_lovelock/results/lovelock-report.json`, field `counters`, entry `leaves`). For $k = 4$ there is no leaf: three entries already use seven different labels in the lower list (j and six more), and a fourth entry would bring two more, nine different labels out of eight.

Step 3: equal label sets. At a leaf the lower list holds $2k + 1$ different labels and so does the upper list. If the two sets of labels differ, some lower label is missing above and the delta is 0 (case c). Only leaves whose two masks are equal are passed to GKD, which then returns $+1$ or -1 (case d: both lists hold the same different labels). The numbers of GKD calls are 696, 32,640, 495,360 and 0, and every one of them gives a nonzero value (record entries `gkdCalls` and `gkdNonzero`, equal for every k). For the scalars $L_{(k)}$ the calls are 108, 7,200, 213,120 and, for the nonzero Euler density $L_{(4)}$, 1,105,920 (entry `scalarGkdCalls`).

Step 4: exact products, collected. Every term that remains is weighted by an explicit call of GKD, multiplied out exactly and added. The program represents every quantity as an exact **Laurent polynomial** (a sum of monomials that may contain negative powers, such as $\cot^{-1} z$) in H, a_4', a_4'' (and the higher derivatives), e^{a_4}, $\sin^{1/3} z$ and $\cot z$, with coefficients that are exact fractions of whole numbers (the files `poly.rs` and `rational.rs` of the crate; every operation that would overflow stops the program instead of rounding). So the result is exact: no rounding happens anywhere.

How the skipping is tested. The steps 1 to 3 rest on the theorem of Section 11.3, and they are tested in four independent ways, none of which skips anything:

- the program itself evaluates the literal, unpruned sum over all $64 \cdot 8^4 = 262144$ index lists of order 1 and all $64 \cdot 8^8 = 1073741824$ index lists of order 2, with GKD weights, at one numerical point, and finds the exact tensors up to rounding errors of 1.40×10^{-15} and 4.41×10^{-14} (relative; checks `k1_brute_force_numeric` and `k2_brute_force_numeric` of `lovelock-report.json`);
- the Revision's sympy checker evaluates the unpruned literal sums of orders 1 and 2 with the author's determinant on every ordered product of nonzero entries (10,140 and 1,581,840

calls) and finds the same tensors exactly (`python-lovelock-report.json`, checks `k1_unpruned_literal_sum_agrees` and `k2_unpruned_literal_sum_agrees`);

- the Revision's Wolfram check calls the author's verbatim definition on every ordered product for $k = 1$ (9,984 calls) and $k = 2$ (1,557,504 calls) and on every leaf for $k = 3$ (1,128,960 calls), and finds the Rust tensors exactly (`wolfram-gkd-report.json`, checks `k1_P_equals_rust_all_64_components` to `k3_P_equals_rust_all_64_components`);
- Notebook 11b repeats the literal sums of orders 1 and 2 with its own GKD (In [16]).

Figure 11b.1 draws the four counts of each order side by side.

11.13 Laplace's rule and the expansion along the column of h

The classical identities of the Lovelock tensors all come from one tool: the expansion of a determinant along a row or a column. Chapter 1 used it only for 3×3 matrices; we prove it in general.

Laplace's rule (PROVED). For a $p \times p$ matrix M and any row r,

$$\det M = \sum_{c=1}^{p} (-1)^{r+c} M_{rc} \det M^{(rc)},$$

where $M^{(rc)}$ is the minor (row r and column c removed); and the same holds along any column c, with the sum over r.

Proof. Every product of the Leibniz formula contains exactly one entry of row r. Group the products by the column c of that entry:

$$\det M = \sum_{c} M_{rc} C_{rc}, \qquad C_{rc} = \sum_{\pi:\ \pi(r)=c} \operatorname{sign}(\pi) \prod_{i \neq r} M_{i\pi(i)}$$

(the Leibniz formula, with the factor of row r taken out of each product). C_{rc}, the **cofactor**, contains no entry of row r. Now let M_* be M with row r replaced by the row that has 1 in column c and 0 elsewhere. Its cofactors are those of M (they contain no entry of row r), and only the column c of its row r is not zero, so

$$\det M_* = 1 \cdot C_{rc} = C_{rc}$$

(the grouping above, applied to M_*). We compute $\det M_*$ a second way. Move row r to the top by $r - 1$ exchanges with the row above it, and column c to the left by $c - 1$ exchanges with the column before it. Each exchange flips the sign of the determinant (rule 3 of Section 1.20 for rows, and for columns rule 3 applied to the transpose, rule 2), so the new matrix M' has

$$\det M' = (-1)^{(r-1)+(c-1)} \det M_* = (-1)^{r+c} \det M_*$$

(and $(-1)^{-2} = 1$). Its first row is $(1, 0, \ldots, 0)$, and removing its first row and column leaves $M^{(rc)}$, because the other rows and columns keep their order. In the Leibniz formula of M' only the

permutations with $\pi(1)=1$ have a nonzero factor in row 1. Such a π has the smallest value 1 at the first place, so the first place forms no inversion with any later place, and its sign is the sign of its restriction to the places $2,\dots,p$, which runs through all permutations of these places. Hence $\det M' = 1\cdot\det M^{(rc)}$, and

$$C_{rc} = \det M_* = (-1)^{r+c}\det M' = (-1)^{r+c}\det M^{(rc)}$$

(the last two equations together, multiplied by $(-1)^{r+c}$, whose square is 1). Inserting this into the grouping gives the rule along row r. Along a column, apply the rule to the transpose (rule 2). □

The expansion of every Lovelock tensor (PROVED). Write the delta of $P_{(k)}$ as the determinant of the $(2k+1)\times(2k+1)$ matrix M whose rows belong to the lower labels $j, j_1, \dots, j_{2k}$ in this order and whose columns belong to the upper labels $h, h_1, \dots, h_{2k}$. Its first column holds $\delta(j,h), \delta(j_1,h), \dots, \delta(j_{2k},h)$. Expand along this column:

$$\delta^{h\,h_1\dots h_{2k}}_{j\,j_1\dots j_{2k}} = \delta^h_j\,\delta^{h_1\dots h_{2k}}_{j_1\dots j_{2k}} + \sum_{s=1}^{2k}(-1)^{(s+1)+1}\,\delta^h_{j_s}\,\delta^{h_1\dots h_{2k}}_{j\,j_1\dots j_{s-1}j_{s+1}\dots j_{2k}}$$

(Laplace's rule along column 1: the entry in row 1 has the sign $(-1)^{1+1}=+1$ and the minor with the rows $j_1,\dots,j_{2k}$; the entry $\delta(j_s,h)$ stands in row $s+1$, and its minor keeps the rows $j, j_1, \dots, j_{s-1}, j_{s+1}, \dots, j_{2k}$). In the minor, move the row of j down past the $s-1$ rows $j_1,\dots,j_{s-1}$:

$$\delta^{h_1\dots h_{2k}}_{j\,j_1\dots j_{s-1}j_{s+1}\dots j_{2k}} = (-1)^{s-1}\,\delta^{h_1\dots h_{2k}}_{j_1\dots j_{s-1}\,j\,j_{s+1}\dots j_{2k}}$$

($s-1$ exchanges of neighbouring rows, each a factor -1 by rule 3; now j stands at the place s, where j_s stood). The two signs combine to $(-1)^{s+2}(-1)^{s-1}=(-1)^{2s+1}=-1$, so

$$\delta^{h\,h_1\dots h_{2k}}_{j\,j_1\dots j_{2k}} = \delta^h_j\,\delta^{h_1\dots h_{2k}}_{j_1\dots j_{2k}} - \sum_{s=1}^{2k}\delta^h_{j_s}\,\delta^{h_1\dots h_{2k}}_{j_1\dots(j\text{ at place }s)\dots j_{2k}}.$$

Multiply by the product of the curvature factors and sum over the $4k$ labels. The first term gives $\delta^h_j L_{(k)}$ (the definition of the scalar). In the term s, the factor $\delta^h_{j_s}$ keeps only $j_s=h$ in the sum over j_s, so h takes the place of j_s in its curvature factor:

$$P_{(k)}{}^h{}_j = \delta^h_j L_{(k)} - \sum_{s=1}^{2k} T_s,$$

$$T_s = \sum \delta^{h_1\dots h_{2k}}_{j_1\dots(j\text{ at place }s)\dots j_{2k}}\; R^{j_1j_2}{}_{h_1h_2}\cdots R^{j_{2k-1}j_{2k}}{}_{h_{2k-1}h_{2k}} \quad (\text{with } h \text{ in place of } j_s).$$

The $2k$ terms are equal. (i) Let s be even, the second upper place of its factor $R^{j_{s-1}h}{}_{h_{s-1}h_s}$. Exchange the rows of j_{s-1} and j in the delta (the places $s-1$ and s), a factor -1 (rule 3), and write $R^{j_{s-1}h}{}_{h_{s-1}h_s} = -R^{hj_{s-1}}{}_{h_{s-1}h_s}$, another factor -1 (antisymmetry). The term is unchanged, and now j stands at the place $s-1$ and h first in its factor: $T_s = T_{s-1}$. (ii) Let $s=2m-1$ be odd with $m>1$, the first place of the m-th factor. Exchange the m-th factor with the first factor: the product of the curvature factors is unchanged (numbers commute). In the delta this exchanges

the pair of rows at the places $2m-1, 2m$ with the pair at the places 1, 2, which is two exchanges of rows, a factor $(-1)^2 = +1$, and the pair of columns h_{2m-1}, h_{2m} with h_1, h_2, again $+1$. After renaming the summed labels the term is T_1. So all $2k$ terms equal T_1, and

$$P_{(k)}{}^{h}{}_{j} = \delta^{h}_{j}\, L_{(k)} - 2k\, Y_{(k)}{}^{h}{}_{j}, \qquad Y_{(k)}{}^{h}{}_{j} = \sum \delta^{h_1 \ldots h_{2k}}_{j\, j_2 \ldots j_{2k}}\, R^{h j_2}{}_{h_1 h_2}\, R^{j_3 j_4}{}_{h_3 h_4} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}.$$

Notebook 11b computes $Y_{(k)}$ with its own GKD sum and checks this expansion exactly for all 64 components and $k = 1, 2, 3$ (In [21]). The Revision's sympy checker derived the same expansion, along the row of h in its convention (`Revision/gkd_lovelock/verification/check_lovelock_gkd.py`, module docstring).

11.14 Order 1 is Einstein's tensor; the trace identity

The pieces of order 1 (PROVED). For $k = 1$ the delta in $Y_{(1)}$ has two labels, and by the formula of Section 11.3

$$Y_{(1)}{}^{h}{}_{j} = \sum_{h_1, h_2, j_2} (\delta^{h_1}_{j}\delta^{h_2}_{j_2} - \delta^{h_2}_{j}\delta^{h_1}_{j_2})\, R^{h j_2}{}_{h_1 h_2}$$

(the 2×2 delta with the lower list (j, j_2) and the upper list (h_1, h_2)),

$$= \sum_{j_2} (R^{h j_2}{}_{j j_2} - R^{h j_2}{}_{j_2 j}) = 2 \sum_{j_2} R^{h j_2}{}_{j j_2} = 2R^{h}{}_{j}$$

(each Kronecker delta keeps one value of a summed label; then the antisymmetry $R^{h j_2}{}_{j_2 j} = -R^{h j_2}{}_{j j_2}$; then the definition of the Ricci tensor). In the same way

$$L_{(1)} = \sum (\delta^{h_1}_{j_1}\delta^{h_2}_{j_2} - \delta^{h_2}_{j_1}\delta^{h_1}_{j_2}) R^{j_1 j_2}{}_{h_1 h_2} = \sum_{h_1, h_2} (R^{h_1 h_2}{}_{h_1 h_2} - R^{h_2 h_1}{}_{h_1 h_2}) = 2 \sum_{h_1, h_2} R^{h_1 h_2}{}_{h_1 h_2} = 2R$$

(the same steps; $\sum_{a,b} R^{ab}{}_{ab} = \sum_a R^{a}{}_{a} = R$).

$P_{(1)} = -4G$ and $E_{(1)} = G$ (PROVED). The expansion of Section 11.13 with $k = 1$ gives

$$P_{(1)}{}^{h}{}_{j} = \delta^{h}_{j} \cdot 2R - 2 \cdot 2R^{h}{}_{j} = -4(R^{h}{}_{j} - \tfrac{1}{2}\delta^{h}_{j} R) = -4\, G^{h}{}_{j}$$

(insert $L_{(1)} = 2R$ and $Y_{(1)} = 2R^{h}{}_{j}$; take out -4; the definition of G), and therefore $E_{(1)} = -P_{(1)}/2^2 = G$. This holds for every metric. For the author's metric the record checks it in all 64 components (`lovelock-report.json` and `python-lovelock-report.json`, check `k1_equals_minus_4_einstein`; `wolfram-gkd-report.json`, check `k1_equals_minus_4_einstein`), and so does Notebook 11b (In [18]). With the Einstein tensor of Section 11.10 the components of $P_{(1)}$ are -4 times those of G: for example $P_{(1)}{}^{x_1}{}_{x_1} = 12a_4'^2 - 4a_4'' - 60H^2$, as the Wolfram record lists (`wolfram-gkd-report.json`, field `measurements`, entry `wolframComponents`). And $L_{(1)} = 2R = 12a_4'^2 - 84H^2$ (record `Revision/gkd_lovelock/results/lovelock-tensors.json`, key `L1`; Notebook 11b, In [22]).

The trace identity (PROVED). Set $j = h$ in the expansion of Section 11.13 and sum over the eight values of h:

$$\sum_h P_{(k)}{}^h{}_h = \Big(\sum_h \delta^h_h\Big) L_{(k)} - 2k \sum_h Y_{(k)}{}^h{}_h = 8\, L_{(k)} - 2k\, L_{(k)} = (8 - 2k)\, L_{(k)}$$

($\delta^h_h = 1$ for each of the eight values; in $\sum_h Y_{(k)}{}^h{}_h$ the label h is summed exactly like j_1 in the definition of the scalar, so renaming it j_1 gives $L_{(k)}$). The factors are 6, 4 and 2 for $k = 1, 2, 3$, the factors of Section 1.44, found there by contracting the delta directly. The record checks the identity exactly (`lovelock-report.json`, checks `k1_trace_identity` to `k3_trace_identity`; `wolfram-gkd-report.json`, checks `k1_trace_equals_6_L1`, `k2_trace_equals_4_L2`, `k3_trace_equals_2_L3`), and so does Notebook 11b (In [22]). For $k = 1$: the trace of $P_{(1)} = -4G$ is $-4(R - 4R) = 12R = 6 \cdot 2R$, as it must be.

11.15 Order 2 is the Gauss-Bonnet tensor; order 3 is the cubic Lovelock density

The piece $Y_{(2)}$, line by line (PROVED). Write $X^h{}_j = Y_{(2)}{}^h{}_j = \sum \delta^{h_1 h_2 h_3 h_4}_{j\, j_2 j_3 j_4}\, R^{h j_2}{}_{h_1 h_2}\, R^{j_3 j_4}{}_{h_3 h_4}$. The delta is a 4×4 determinant with the rows j, j_2, j_3, j_4 and the columns h_1, h_2, h_3, h_4. Expand it along its first row, the row of j, whose entries are $\delta(j, h_c) = \delta^{h_c}_j$ with the signs $+, -, +, -$ (Laplace's rule, $(-1)^{1+c}$). This gives four terms; in each, the factor $\delta^{h_c}_j$ puts j in place of h_c in the curvature factors. We use the result of order 1 in the form

$$\sum \delta^{a\, c_1 c_2}_{b\, d_1 d_2} R^{d_1 d_2}{}_{c_1 c_2} = P_{(1)}{}^a{}_b = 2R\, \delta^a_b - 4R^a{}_b$$

(Section 11.14, with the labels renamed), and write the summed labels as $b = j_2$, $c = j_3$, $d = j_4$.

Term 1 ($c = 1$, sign $+$): the minor has the rows j_2, j_3, j_4 and the columns h_2, h_3, h_4:

$$\sum R^{h j_2}{}_{j h_2}\, \delta^{h_2 h_3 h_4}_{j_2 j_3 j_4} R^{j_3 j_4}{}_{h_3 h_4} = \sum_{j_2, h_2} R^{h j_2}{}_{j h_2} (2R\, \delta^{h_2}_{j_2} - 4R^{h_2}{}_{j_2}) = 2R\, R^h{}_j - 4 \sum_{b,x} R^{hb}{}_{jx} R^x{}_b$$

(the order-1 result with $a = h_2$, $b = j_2$; then $\delta^{h_2}_{j_2}$ sets $h_2 = j_2$ and $\sum_{j_2} R^{h j_2}{}_{j j_2} = R^h{}_j$; the summed labels renamed $b = j_2$, $x = h_2$).

Term 2 ($c = 2$, sign $-$): the minor has the columns h_1, h_3, h_4, and h_2 becomes j:

$$-\sum R^{h j_2}{}_{h_1 j} (2R\, \delta^{h_1}_{j_2} - 4R^{h_1}{}_{j_2}) = -2R \sum_{j_2} R^{h j_2}{}_{j_2 j} + 4 \sum R^{h j_2}{}_{h_1 j} R^{h_1}{}_{j_2} = 2R\, R^h{}_j - 4 \sum_{b,x} R^{hb}{}_{jx} R^x{}_b$$

(the same steps; then $R^{h j_2}{}_{j_2 j} = -R^{h j_2}{}_{j j_2}$ and $R^{h j_2}{}_{h_1 j} = -R^{h j_2}{}_{j h_1}$ by antisymmetry). Terms 1 and 2 together: $4R\, R^h{}_j - 8 \sum R^{hb}{}_{jx} R^x{}_b$.

Term 3 ($c = 3$, sign $+$): h_3 becomes j, and the minor $\delta^{h_1 h_2 h_4}_{j_2 j_3 j_4}$ has the rows j_2, j_3, j_4 and the columns h_1, h_2, h_4. Expand it along its third column, the column of h_4, with the signs $+, -, +$:

$$\delta^{h_1 h_2 h_4}_{j_2 j_3 j_4} = \delta^{h_4}_{j_2}\, \delta^{h_1 h_2}_{j_3 j_4} - \delta^{h_4}_{j_3}\, \delta^{h_1 h_2}_{j_2 j_4} + \delta^{h_4}_{j_4}\, \delta^{h_1 h_2}_{j_2 j_3}$$

(Laplace's rule along column 3; the sign of row r is $(-1)^{r+3}$). Multiply by $R^{hj_2}{}_{h_1h_2}R^{j_3j_4}{}_{jh_4}$ and sum, using $\sum_{h_1,h_2}\delta^{h_1h_2}_{uv}R^{hj_2}{}_{h_1h_2} = R^{hj_2}{}_{uv} - R^{hj_2}{}_{vu} = 2R^{hj_2}{}_{uv}$:

$$2\sum R^{hj_2}{}_{j_3j_4}R^{j_3j_4}{}_{jj_2} - 2\sum R^{hj_2}{}_{j_2j_4}R^{j_3j_4}{}_{jj_3} + 2\sum R^{hj_2}{}_{j_2j_3}R^{j_3j_4}{}_{jj_4}$$

(each δ^{h_4} puts the matching lower label in place of h_4). In the second sum $\sum_{j_2} R^{hj_2}{}_{j_2j_4} = -R^h{}_{j_4}$ and $\sum_{j_3} R^{j_3j_4}{}_{jj_3} = -R^{j_4}{}_j$; in the third $\sum_{j_2} R^{hj_2}{}_{j_2j_3} = -R^h{}_{j_3}$ and $\sum_{j_4} R^{j_3j_4}{}_{jj_4} = R^{j_3}{}_j$ (antisymmetry, then the definition of the Ricci tensor). So term 3 is

$$2\sum R^{hb}{}_{cd}R^{cd}{}_{jb} - 2\sum_c R^h{}_cR^c{}_j - 2\sum_c R^h{}_cR^c{}_j = 2\sum R^{hb}{}_{cd}R^{cd}{}_{jb} - 4\sum_c R^h{}_cR^c{}_j.$$

Term 4 ($c = 4$, sign $-$): h_4 becomes j, the factor is $R^{j_3j_4}{}_{h_3j} = -R^{j_3j_4}{}_{jh_3}$, and the two minus signs give $+\sum \delta^{h_1h_2h_3}_{j_2j_3j_4}R^{hj_2}{}_{h_1h_2}R^{j_3j_4}{}_{jh_3}$, which is term 3 with h_4 renamed h_3. So term 4 equals term 3. Adding the four terms:

$$X^h{}_j = 4R\,R^h{}_j - 8\sum R^{hb}{}_{jx}R^x{}_b - 8\sum_c R^h{}_cR^c{}_j + 4\sum R^{hb}{}_{cd}R^{cd}{}_{jb}.$$

$L_{(2)}$ is four times the Gauss-Bonnet scalar (PROVED). By the trace argument of Section 11.14, $L_{(2)} = \sum_h X^h{}_h$:

$$\begin{aligned} L_{(2)} &= 4R^2 - 8\sum R^b{}_xR^x{}_b - 8\sum R^h{}_cR^c{}_h + 4\sum R^{ab}{}_{cd}R^{cd}{}_{ab} \\ &= 4\Big(R^2 - 4\sum_{a,b} R^a{}_bR^b{}_a + \sum R^{ab}{}_{cd}R^{cd}{}_{ab}\Big) = 4\,\mathrm{GB} \end{aligned}$$

($\sum_h R^{hb}{}_{hx} = R^b{}_x$; the two Ricci squares are the same sum; then 4 taken out). $\mathrm{GB} = R^2 - 4R^a{}_bR^b{}_a + R^{ab}{}_{cd}R^{cd}{}_{ab}$ is the classical **Gauss-Bonnet scalar**.

$P_{(2)}$ is -8 times the Gauss-Bonnet tensor (PROVED). The expansion of Section 11.13 with $k = 2$:

$$P_{(2)}{}^h{}_j = \delta^h_j\,4\,\mathrm{GB} - 4X^h{}_j = -16R\,R^h{}_j + 32\sum R^{hb}{}_{jx}R^x{}_b + 32\sum_c R^h{}_cR^c{}_j - 16\sum R^{hb}{}_{cd}R^{cd}{}_{jb} + 4\,\delta^h_j\,\mathrm{GB}$$

(insert $L_{(2)}$ and X; multiply out). The classical Gauss-Bonnet tensor of Lanczos, which uses no generalized delta, is (in the mixed form of the record)

$$2\mathcal{H}^h{}_j = 4\Big(R\,R^h{}_j - 2\sum_a R^h{}_aR^a{}_j - 2\sum_{a,b} R^{ha}{}_{jb}R^b{}_a + \sum_{a,b,c} R^{ha}{}_{bc}R^{bc}{}_{ja}\Big) - \delta^h_j\,\mathrm{GB}.$$

Multiplying by -4 gives $-8\mathcal{H}^h{}_j = -16R\,R^h{}_j + 32\sum R^h{}_aR^a{}_j + 32\sum R^{ha}{}_{jb}R^b{}_a - 16\sum R^{ha}{}_{bc}R^{bc}{}_{ja} + 4\delta^h_j\,\mathrm{GB}$, which is $P_{(2)}{}^h{}_j$ term by term after renaming the summed labels ($b \to a$, $x \to b$ in the second term; $b \to a$, $c \to b$, $d \to c$ in the fourth). So $P_{(2)} = -8\mathcal{H}$ and $E_{(2)} = -P_{(2)}/8 = \mathcal{H}$ for every metric: the second Lovelock tensor is the Gauss-Bonnet tensor. For the author's metric the record checks it

in all 64 components (`python-lovelock-report.json`, checks `k2_equals_minus_8_gauss_bonnet` and `L2_equals_4_gauss_bonnet`), and so does Notebook 11b (In [19]). The record also found the factors -4 and -8 without any algebra, from literal sums on random curvature tensors in four and five dimensions (checks `normalisation_P1_derived_minus_4` and `normalisation_P2_derived_minus_8`). With $L_{(2)} = -96a_4'^4 - 2112a_4'^2H^2 + 3360H^4$ (record key `L2`), the Gauss-Bonnet scalar of the author's metric is $\mathrm{GB} = L_{(2)}/4 = -24a_4'^4 - 528a_4'^2H^2 + 840H^4$.

Order 3 (PROVED for the author's metric by exact computation; the general formula quoted). The third scalar is the **cubic Lovelock density**,

$$L_{(3)} = 8\big(2T_1 + 8T_2 + 24T_3 + 3T_4 + 24T_5 + 16T_6 - 12T_7 + T_8\big),$$

with the eight cubic invariants $T_1 = R^{ab}{}_{cd}R^{cd}{}_{ef}R^{ef}{}_{ab}$, $T_2 = R^{ab}{}_{cd}R^{ce}{}_{bf}R^{df}{}_{ae}$, $T_3 = R^{ab}{}_{cd}R^{cd}{}_{be}R^{e}{}_{a}$, $T_4 = R\,R^{ab}{}_{cd}R^{cd}{}_{ab}$, $T_5 = R^{ab}{}_{cd}R^{c}{}_{a}R^{d}{}_{b}$, $T_6 = R^{a}{}_{b}R^{b}{}_{c}R^{c}{}_{a}$, $T_7 = R\,R^{a}{}_{b}R^{b}{}_{a}$, $T_8 = R^3$ (every label summed). We do not derive these coefficients by hand: the record determined them from literal sums on nine random curvature tensors in six dimensions (a system of nine equations for eight unknowns with a unique solution; `python-lovelock-report.json`, check `normalisation_L3_cubic_derived`), and checked the identity exactly for the author's metric (check `L3_equals_8_cubic_lovelock_density`); Notebook 11b checks it again (In [20]). For the author's metric $L_{(3)} = 1152a_4'^6 + 31104a_4'^4H^2 + 100224a_4'^2H^4 - 40320H^6$ (record key `L3`).

11.16 Example: the three Lovelock tensors computed twice

Notebook 11b computes the three Lovelock tensors of the author's metric in two independent ways and checks Sections 11.10 to 11.15. It builds and runs the Revision Rust program `lovelock_gkd`, which computes everything exactly from the metric alone (the author's metric of 2026-10-14, with its second function $b_4(x_4)$), runs its 19 checks and writes four files; the notebook compares three of the four files with the committed Revision records byte for byte, and the fourth, the report `lovelock-report.json`, apart from its two floating-point numbers (the rounding errors measured by its two brute-force checks, whose last digits may depend on the computer). Then it recomputes the Riemann tensor with sympy, for a general b_4, and compares all 156 nonzero components with the record; from there on it works on the background $b_4 = 1$; draws the plane curvatures, the whole Riemann tensor and the mixed terms, which cancel at $b_4 = 1$ and leave $\frac{3}{2}H\cot z\, b_4'/b_4$ with b_4; recomputes the three tensors and scalars with its own Python GKD sum and its own exact arithmetic, reproduces every counter of the Rust sums and all 3×64 components; repeats the sums of orders 1 and 2 literally; checks the expansion of Section 11.13, the identities $P_{(1)} = -4G$, $P_{(2)} = -8\mathcal{H}$, the cubic density, the trace identities and $P_{(4)} = 0$; draws the components of $E_{(1)}, E_{(2)}, E_{(3)}$ at one moment of a deflating history; and checks that every check it quotes from the records is there. It needs Rust and takes about a minute (45.7 seconds when it was built on 2026-10-15; provenance file `Revision/textbook/notebooks/11b_lovelock_tensors.PROVENANCE.md`). It prints 38 PASS lines, draws five figures and ends with the line ALL 38 CHECKS PASSED (notebook 11b).

11.17 How to run Notebook 11b

Step 1. What this notebook does and what it needs.

Notebook 11b (The three Lovelock tensors of the author's metric, computed with GKD) is the file `Revision/textbook/notebooks/11b_lovelock_tensors.ipynb` of the repository Dirac_claude. It builds the Revision Rust program lovelock_gkd with cargo inside the notebook when the program file is missing (a few seconds, up to a minute on a slow computer; about a second when it is up to date) and runs it; the program computes exactly the curvature of the author's metric and the three Lovelock tensors of Lovelock's equation (4.38) in eight dimensions with GKD, and the notebook checks that its four output files are byte for byte the committed Revision records (the report apart from two floating-point rounding errors, which must stay below 1e-10). Then it recomputes the Riemann tensor with sympy and the three Lovelock tensors and scalars with its own Python GKD sum, compares every component exactly with the records, reproduces the counters of the Rust sums, repeats the sums of orders 1 and 2 literally without skipping any term, derives and checks the expansion of every Lovelock tensor along the column of its free upper label, and checks that the first Lovelock tensor is -4 times the Einstein tensor, the second -8 times the Gauss-Bonnet tensor, the third scalar 8 times the cubic Lovelock density, that the traces obey the trace identity and that the fourth tensor vanishes; it checks again that every check it quotes from the Revision records is there with the verdict PASS; it draws five teaching figures, among them the components of the three tensors. The Rust program writes its four output files (curvature.json, lovelock-tensors.json, lovelock-components.md and lovelock-report.json) into the folder `Revision/gkd_lovelock/code/target/textbook_11b`, inside the Rust build folder, which git ignores. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the Rust program lovelock_gkd, which is part of the repository and is built on your computer.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download `rustup-init.exe` from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run `rustup-init.exe` again). macOS and Linux: run the command below and

accept the default choice (on Linux first run `sudo apt install build-essential`, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file `Revision/gkd_lovelock/code/target/release/lovelock_gkd` (on Windows with the ending `.exe`). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 11b_lovelock_tensors.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 11b_lovelock_tensors.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 11b_lovelock_tensors.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/11b.captions.json`
- `Revision/textbook/figures/11b_1_work_of_the_sums.png`
- `Revision/textbook/figures/11b_2_curvature_of_planes.png`
- `Revision/textbook/figures/11b_3_riemann_matrix.png`
- `Revision/textbook/figures/11b_4_mixing_terms_cancel.png`
- `Revision/textbook/figures/11b_5_lovelock_component_tables.png`

It changes no other file of the repository except the Rust build folder `target` next to each `Cargo.toml` it builds (inside it the notebook keeps the raw output of its program runs in `Revision/gkd_lovelock/code/target/textbook_11b`, which git ignores); running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of the notebook exist
ALL 38 CHECKS PASSED (notebook 11b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/11b_lovelock_tensors.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 11b_lovelock_tensors.ipynb
python -m nbconvert --execute --inplace 11b_lovelock_tensors.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this terminal.
- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build again.
- AssertionError: check failed: the program wrote curvature.json equal to the Revision record byte for byte (or the same message for one of the other three files): The file that the program wrote differs from the committed record. Run git status in the repository folder to see whether the records or the Rust source were changed, and restore both with the command below.

```
git checkout -- Revision/gkd_lovelock
```

11.18 Notebook 11b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/11b_lovelock_tensors.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Einstein's field equations equate the Einstein tensor $G$, built from the curvature
of space-time, to the energy and momentum of matter. In eight dimensions Lovelock's
theorem allows two more tensors of the same kind, built from products of two and of
three curvature tensors. Together with Einstein's they are the three **Lovelock
tensors** $P_{(1)}, P_{(2)}, P_{(3)}$ of Lovelock's equation (4.38), which the
author's notebook quotes. This notebook computes them for the author's metric, in
two independent ways, and checks them. It

- builds the Revision Rust program `lovelock_gkd` with cargo and runs it: from the
  metric alone it computes exactly the Christoffel symbols, the Riemann tensor and
  the three Lovelock tensors (with GKD, the generalized Kronecker delta), checks 19
  identities, and writes four files; the notebook checks that the four files are,
  byte for byte, the committed Revision records;
- draws how much work the sums are, and how the program reduces it;
- recomputes the Riemann tensor with sympy and compares all 156 nonzero components
  exactly with the record; draws the curvature of every coordinate plane and the
  whole Riemann tensor, and shows why the mixed $x_4$-$x_0$ terms cancel;
- recomputes the three Lovelock tensors and the three Lovelock scalars in Python
  with its own GKD sum and its own exact polynomial arithmetic, reproduces the
  counters of the Rust sums, and compares all $3 \times 64$ components exactly;
- repeats the sums of orders 1 and 2 LITERALLY, calling GKD on every ordered
  product of curvature entries without skipping anything, and finds the same
  tensors: the skipping changes nothing;
- derives, line by line, the expansion of every Lovelock tensor along the column
  of its free upper label, and checks it exactly for $k = 1, 2, 3$;
- checks three classical identities: $P_{(1)} = -4\,G$ (Einstein),
  $P_{(2)} = -8\,\mathcal{H}$ with the Gauss-Bonnet tensor $\mathcal{H}$, and
  $L_{(3)} = 8 \times$ the cubic Lovelock density; the trace identities; and
  $P_{(4)} = 0$;
- draws the components of the three normalised Lovelock tensors at one moment of
  a deflating history;
- reads the Revision verification reports once more and checks that every check
  it quotes from them is there with the verdict PASS.

It draws five figures and takes about one and a half minutes.
```

Text cell:

```
## 2. How to run this notebook
```

Step 1. What this notebook does and what it needs.

Notebook 11b (The three Lovelock tensors of the author's metric, computed with GKD) is the file ‘Revision/textbook/notebooks/11b_lovelock_tensors.ipynb‘ of the repository Dirac_claude. It builds the Revision Rust program lovelock_gkd with cargo inside the notebook when the program file is missing (a few seconds, up to a minute on a slow computer; about a second when it is up to date) and runs it; the program computes exactly the curvature of the author's metric and the three Lovelock tensors of Lovelock's equation (4.38) in eight dimensions with GKD, and the notebook checks that its four output files are byte for byte the committed Revision records (the report apart from two floating-point rounding errors, which must stay below 1e-10). Then it recomputes the Riemann tensor with sympy and the three Lovelock tensors and scalars with its own Python GKD sum, compares every component exactly with the records, reproduces the counters of the Rust sums, repeats the sums of orders 1 and 2 literally without skipping any term, derives and checks the expansion of every Lovelock tensor along the column of its free upper label, and checks that the first Lovelock tensor is -4 times the Einstein tensor, the second -8 times the Gauss-Bonnet tensor, the third scalar 8 times the cubic Lovelock density, that the traces obey the trace identity and that the fourth tensor vanishes; it checks again that every check it quotes from the Revision records is there with the verdict PASS; it draws five teaching figures, among them the components of the three tensors. The Rust program writes its four output files (curvature.json, lovelock-tensors.json, lovelock-components.md and lovelock-report.json) into the folder ‘Revision/gkd_lovelock/code/target/textbook_11b‘, inside the Rust build folder, which git ignores. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the Rust program lovelock_gkd, which is part of the repository and is built on your computer.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download ‘rustup-init.exe‘ from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run ‘rustup-init.exe‘ again). macOS and Linux: run the command below and accept the default choice (on Linux first run ‘sudo apt install build-essential‘, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
    curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
    cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
    cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file ‘Revision/gkd_lovelock/code/target/release/lovelock_gkd‘ (on Windows with the ending ‘.exe‘). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 11b_lovelock_tensors.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 11b_lovelock_tensors.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 11b_lovelock_tensors.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/11b.captions.json‘
- ‘Revision/textbook/figures/11b_1_work_of_the_sums.png‘
- ‘Revision/textbook/figures/11b_2_curvature_of_planes.png‘
- ‘Revision/textbook/figures/11b_3_riemann_matrix.png‘
- ‘Revision/textbook/figures/11b_4_mixing_terms_cancel.png‘
- ‘Revision/textbook/figures/11b_5_lovelock_component_tables.png‘

It changes no other file of the repository except the Rust build folder ‘target‘ next to each ‘Cargo.toml‘ it builds (inside it the notebook keeps the raw output of its program runs in ‘Revision/gkd_lovelock/code/target/textbook_11b‘, which git ignores); running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of the notebook exist
ALL 38 CHECKS PASSED (notebook 11b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/11b_lovelock_tensors.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was

  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 11b_lovelock_tensors.ipynb
python -m nbconvert --execute --inplace 11b_lovelock_tensors.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this terminal.
- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build again.
- AssertionError: check failed: the program wrote curvature.json equal to the Revision record byte for byte (or the same message for one of the other three files): The file that the program wrote differs from the committed record. Run git status in the repository folder to see whether the records or the Rust source were changed, and restore both with the command below.

```
git checkout -- Revision/gkd_lovelock
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 11b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 11b (The three Lovelock tensors of the author’s metric, computed with GKD) is
```

```
# the file Revision/textbook/notebooks/11b_lovelock_tensors.ipynb of the repository
# Dirac_claude. It builds the Revision Rust program lovelock_gkd with cargo inside the
# notebook when the program file is missing (a few seconds, up to a minute on a slow
# computer; about a second when it is up to date) and runs it; the program computes
# exactly the curvature of the author's metric and the three Lovelock tensors of
# Lovelock's equation (4.38) in eight dimensions with GKD, and the notebook checks that
# its four output files are byte for byte the committed Revision records (the report
# apart from two floating-point rounding errors, which must stay below 1e-10). Then it
# recomputes the Riemann tensor with sympy and the three Lovelock tensors and scalars
# with its own Python GKD sum, compares every component exactly with the records,
# reproduces the counters of the Rust sums, repeats the sums of orders 1 and 2 literally
# without skipping any term, derives and checks the expansion of every Lovelock tensor
# along the column of its free upper label, and checks that the first Lovelock tensor is
# -4 times the Einstein tensor, the second -8 times the Gauss-Bonnet tensor, the third
# scalar 8 times the cubic Lovelock density, that the traces obey the trace identity and
# that the fourth tensor vanishes; it checks again that every check it quotes from the
# Revision records is there with the verdict PASS; it draws five teaching figures, among
# them the components of the three tensors. The Rust program writes its four output files
# (curvature.json, lovelock-tensors.json, lovelock-components.md and
# lovelock-report.json) into the folder Revision/gkd_lovelock/code/target/textbook_11b,
# inside the Rust build folder, which git ignores. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It also needs Rust (the program
# cargo, version 1.91.1 or newer), because it runs the Rust program lovelock_gkd, which
# is part of the repository and is built on your computer.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
```

```
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
```

```
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. INSTALL RUST AND BUILD THE RUST PROGRAM (RUST ONCE PER COMPUTER, THE BUILD ONCE
# PER PROGRAM).
#
# Windows: download rustup-init.exe from https://rustup.rs, run it and accept the default
# choices; if it reports that the Visual Studio C++ Build Tools are missing, let it
# install them (or install the workload "Desktop development with C++" from
# https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run rustup-init.exe
# again). macOS and Linux: run the command below and accept the default choice (on Linux
# first run sudo apt install build-essential, which provides the linker that Rust needs).
#
# macOS (zsh) and Linux (bash):
#     curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
#
# Then close the terminal, open a new one, do Step 4 again, and check the version of
# cargo; it must print 1.91.1 or a newer version:
#
# Windows, macOS and Linux:
#     cargo --version
#
# Build the program with the following command, in the repository folder (the same
# command on all three systems):
#
# Windows, macOS and Linux:
```

```
#     cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
#
# The first build takes about 1 minute; later builds reuse the result and take a few
# seconds. The program is then the file
# Revision/gkd_lovelock/code/target/release/lovelock_gkd (on Windows with the ending
# .exe). The notebook runs the same build command itself before it uses the program (it
# takes a second when the program is up to date), so the notebook also works if you skip
# this build; building here first shows any problem with Rust before the notebook starts.
#
# STEP 6. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 11b_lovelock_tensors.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 7. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 11b_lovelock_tensors.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 11b_lovelock_tensors.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 8. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/11b.captions.json
# - Revision/textbook/figures/11b_1_work_of_the_sums.png
# - Revision/textbook/figures/11b_2_curvature_of_planes.png
# - Revision/textbook/figures/11b_3_riemann_matrix.png
# - Revision/textbook/figures/11b_4_mixing_terms_cancel.png
# - Revision/textbook/figures/11b_5_lovelock_component_tables.png
```

```
#
# It changes no other file of the repository except the Rust build folder target next to
# each Cargo.toml it builds (inside it the notebook keeps the raw output of its program
# runs in Revision/gkd_lovelock/code/target/textbook_11b, which git ignores); running it
# headless or saving it in JupyterLab also rewrites the notebook file itself. It does not
# use the internet while it runs. The files it writes are the same files that are stored
# in the repository (on another computer a figure may differ in a few bytes, which is
# harmless). To get the stored versions back, run this command in the repository folder
# (it also undoes every change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files of the notebook exist
#     ALL 38 CHECKS PASSED (notebook 11b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 9. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/11b_lovelock_tensors.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 11b_lovelock_tensors.ipynb
#     python -m nbconvert --execute --inplace 11b_lovelock_tensors.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
```

```
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "cargo is not recognized" or "command not found: cargo" or "cargo was not found":
#   open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from
#   this terminal.
# - "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the
#   C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build
#   again.
# - AssertionError: check failed: the program wrote curvature.json equal to the Revision
#   record byte for byte (or the same message for one of the other three files): The file
#   that the program wrote differs from the committed record. Run git status in the
#   repository folder to see whether the records or the Rust source were changed, and
#   restore both with the command below.
#     git checkout -- Revision/gkd_lovelock
#
# ------------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$ of the author's metric: $x_1, x_2, x_3$ ordinary
  space, $x_4$ the time, $x_5, x_6, x_7$ the three extra times, $x_0$ the hidden
  direction. The programs number them $0, \dots, 7$.
- **Metric** $g_{ab}$: the table of numbers that gives lengths and times; here it is
  diagonal (only $g_{11}, \dots, g_{00}$ are not zero). **Inverse metric**
  $g^{aa} = 1/g_{aa}$ for a diagonal metric.
- **Index up, index down**: a tensor component carries upper and lower coordinate
  labels, such as $R^{ab}{}_{cd}$; a label is raised with the inverse metric.
- **Christoffel symbol** $\Gamma^a{}_{bc}$: the combination of first derivatives of
  the metric that says how the coordinate directions turn from point to point.
- **Riemann tensor** $R^a{}_{bcd}$: the combination of Christoffel symbols and their
  derivatives that measures curvature. We use mostly $R^{ab}{}_{cd} =
  g^{bb} R^a{}_{bcd}$, which changes sign when $a, b$ or $c, d$ are exchanged.
- **Curvature of a plane** $K(a, b) = R^{ab}{}_{ab}$ (no sum): the curvature of the
  surface spanned by the directions $x_a$ and $x_b$.
- **Ricci tensor** $R^h{}_j = \sum_a R^{ha}{}_{ja}$, **Ricci scalar**
  $R = \sum_h R^h{}_h$, **Einstein tensor** $G^h{}_j = R^h{}_j - \tfrac12
  \delta^h{}_j R$.
- **Generalized Kronecker delta, GKD**: the number $+1$, $-1$ or $0$ that weights
  every term of the Lovelock sums (built and tested in Notebook 11a).
- **Lovelock tensor** $P_{(k)}{}^h{}_j$ of order $k$, **Lovelock scalar**
  $L_{(k)}$: defined in section 4. **Gauss-Bonnet tensor**: the classical name of
  the order-2 Lovelock tensor.
- **Exact**: computed with whole numbers and fractions, without rounding.
  **Polynomial, monomial**: a polynomial is a sum of monomials, each a number times
  powers of symbols such as $H^2 a_4'^2$; a **Laurent polynomial** may also contain
  negative powers, such as $\cot^{-1}$.
- **Brute force**, **literal sum**: a computation that tries every case without any
  shortcut. **Skipping** (pruning): leaving out terms that are known to be zero.
- **Expansion of a determinant along a column** (Laplace's rule): the determinant
  equals the sum, over the entries of one column, of the entry times
  $(-1)^{\text{row} + \text{column}}$ times the determinant of the smaller matrix
  that is left when the entry's row and column are removed (its **minor**).
  Exchanging two neighbouring rows of a matrix changes the sign of its determinant.
- **Revision record**: a file committed under 'Revision/' that holds a result.
  **Byte for byte**: two files equal in every byte.
```

```
## 4. The physical and mathematical situation
```

The metric. The author's primordial metric of 2026-10-14 is diagonal,

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4} s,\ e^{2a_4} s,\ e^{2a_4} s,\ -1,\
  -e^{-2a_4} b_4 s,\ -e^{-2a_4} b_4 s,\ -e^{-2a_4} b_4 s\big),\qquad
  s = \sin^{1/3} z,\quad z = 6 H x_0,$$

in the order $x_0, \dots, x_7$, with a constant $H > 0$ and two functions $a_4(x_4)$ and $b_4(x_4) > 0$ of the time; $0 < z < \pi/2$. Lengths along ordinary space carry the scale factor $e^{a_4} \sin^{1/6} z$ (it INFLATES as a_4 grows), lengths along the three extra times the factor $e^{-a_4} b_4^{1/2} \sin^{1/6} z$ (they DEFLATE exponentially), and $\sqrt{|\det g|} = b_4^{3/2}\cos z$. The background of the Revision records is $b_4 = 1$. Primes are derivatives with respect to the time: $a_4' = da_4/dx_4$, $a_4'' = d^2a_4/dx_4^2$. Below, A_1 stands for a_4', A_2 for a_4'', B_0, B_1, B_2 for b_4, b_4', b_4'', and C for $\cot z$.

Curvature (the convention of Misner, Thorne and Wheeler, used by the Revision):

$$\Gamma^a{}_{bc} = \tfrac12 g^{aa}\big(\partial_b g_{ac} + \partial_c g_{ab}
  - \partial_a g_{bc}\big),$$

$$R^a{}_{bcd} = \partial_c \Gamma^a{}_{db} - \partial_d \Gamma^a{}_{cb}
  + \sum_e \big(\Gamma^a{}_{ce} \Gamma^e{}_{db} - \Gamma^a{}_{de} \Gamma^e{}_{cb}\big),
  \qquad R^{ab}{}_{cd} = g^{bb} R^a{}_{bcd}.$$

(For a diagonal metric the sum $g^{ad}(\dots)$ of the general formula keeps only $d = a$.)

Lovelock's equation (4.38) gives, for n dimensions with $n = 2m$ even, the tensors

$$P_{(k)}{}^h{}_j = \sum \delta^{h\, h_1 \dots h_{2k}}_{j\, j_1 \dots j_{2k}}\,
  R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}},$$

where the sum runs over all $4k$ labels $h_1, \dots, h_{2k}, j_1, \dots, j_{2k}$ and δ is the generalized Kronecker delta with the upper list $(h, h_1, \dots, h_{2k})$ and the lower list $(j, j_1, \dots, j_{2k})$. The orders are $k = 1, \dots, m - 1$; for $n = 8$, $m = 4$ and $k = 1, 2, 3$. The **Lovelock scalar** $L_{(k)}$ is the same sum without the free pair h, j. The equation itself (with constants α_k and λ) is written with the densities $A_{(k)}{}^{lh} = \sqrt{|\det g|}\, g^{ll} P_{(k)}{}^h{}_l$; the usual normalisation is $E_{(k)} = -P_{(k)}/2^{k+1}$, so that $E_{(1)}$ is Einstein's tensor G. The field equations of a_4 built from them are the subject of chapter 12.

Why the sum must be organised. Written literally, each component is a sum over 8^{4k} lists of labels: $8^{12} \approx 6.9 \times 10^{10}$ terms per component for $k = 3$. Two facts make it small. First, a term with a vanishing curvature factor vanishes, so only the 156 nonzero $R^{ab}{}_{cd}$ need to be combined. Second, a term in which a label repeats in the upper or in the lower list has GKD $= 0$ (Notebook 11a), so such combinations are skipped as soon as they appear. Every term that remains is weighted by an explicit call of GKD. The Rust program and the Python code of section 8 both follow this plan, written independently; the program also checks it against the literal, unpruned sum for $k = 1$ and $k = 2$ at a numerical point ("brute force").

Status. The tensors are exact polynomials, computed by two independent programs and verified again by the Revision's sympy and Wolfram checks (records ‘python-lovelock-report.json‘, 49 checks, and ‘wolfram-gkd-report.json‘, 29 checks): PROVED by exact computation. No physical assumption enters this notebook: it is the geometry of the given metric.

Text cell:

5. The Rust program ‘lovelock_gkd‘

The next cell builds the program with cargo, through the helper ‘rust_program‘ of the set-up cell (it runs ‘cargo build --release‘ for the crate ‘Revision/gkd_lovelock/code‘ and returns the path of the program file). When the program file is missing, cargo compiles it: 4 seconds on the computer that built the book, up to a minute on a slow computer. When the program is up to date, cargo only checks that, in about a second. The crate has no dependencies, so cargo downloads nothing.

In [2]:

```
program = rust_program("Revision/gkd_lovelock/code/Cargo.toml", "lovelock_gkd")
```

Out [2]:

```
Rust program lovelock_gkd is built and ready.
```

Text cell:

The next cell runs ‘lovelock_gkd lovelock --output FOLDER --brute-force-k2‘. FOLDER is ‘Revision/gkd_lovelock/code/target/textbook_11b‘, inside the crate's build folder ‘target‘, which git ignores; so the run adds no file to the repository. The program computes everything exactly from the metric, runs its 19 checks (the option ‘--brute-force-k2‘ adds the literal unpruned sum of order 2 over 1,073,741,824 index lists at one numerical point) and writes four files: ‘curvature.json‘, ‘lovelock-tensors.json‘, ‘lovelock-components.md‘ and ‘lovelock-report.json‘. It takes about 15 seconds.

The program prints one line per check (‘PASS - name: detail‘ or ‘FAIL - ...‘), one line per order k with its counters and run time, and an information line with the eighth-order scalar $L_{(4)}$. The cell prints the names of the checks with their verdicts, and $L_{(4)}$ in a readable form (the program writes a_4' as ‘Derivative[1][a4][x4]‘, Mathematica's notation); it leaves out the run times, which differ from run to run. ‘re.match‘ and ‘re.search‘ read parts of a line with a pattern (a regular expression).

In [3]:

```
import re  # regular expressions: patterns that read parts of a line of text

RESULTS = "Revision/gkd_lovelock/results"  # the folder of the Revision records
OUT_FOLDER = REPO / "Revision" / "gkd_lovelock" / "code" / "target" / "textbook_11b"

Text cell:

```
The next cell compares the four files that the program has just written with the
committed Revision records in ‘Revision/gkd_lovelock/results‘, byte for byte
(‘read_bytes()‘ reads a file as a sequence of bytes). Equal bytes mean that the
program, built on this computer, has reproduced every symbol of the Revision’s
results.

The first three files hold only exact whole numbers and fractions, so they must be
equal byte for byte on every computer. The fourth, ‘lovelock-report.json‘, holds
two decimal numbers: the largest relative deviation between the exact $P_{(1)}$,
$P_{(2)}$ and their literal brute-force sums, evaluated in floating point at one
numerical point (on the build computer $1.40 \times 10^{-15}$ and
$4.41 \times 10^{-14}$, rounding errors of the decimal arithmetic). The last digits
of such rounding errors can depend on the mathematics library of the operating
system (the functions $\sin$ and $\cos$). So the cell compares this file byte for
byte after replacing these two numbers by the letter X in both texts
(‘re.sub‘), and checks separately that both numbers are below the program’s own
limit $10^{-10}$. On the computer that built the book the file is equal byte for
byte without any replacement.
```

```
## 6. How much work the sums are

The report ‘lovelock-report.json‘ (just reproduced) lists, for each order $k$, the
**leaves** (the combinations of $k$ nonzero curvature entries that survive the
skipping of repeated labels, for all 64 pairs $(h, j)$), the **GKD calls** (the
leaves whose upper and lower label sets are equal, so that GKD may be nonzero; GKD
is then called) and the number of nonzero GKD values. The next cell reads them and
compares them with two counts without any shortcut: the number of ordered
combinations of $k$ of the 156 nonzero entries for the 64 pairs, $64 \cdot 156^k$,
and the literal number of index lists, $64 \cdot 8^{4k}$. For $k = 4$ nothing
survives: a combination of four entries needs nine different labels in each list,
and there are only eight.
```

In [5]:

```

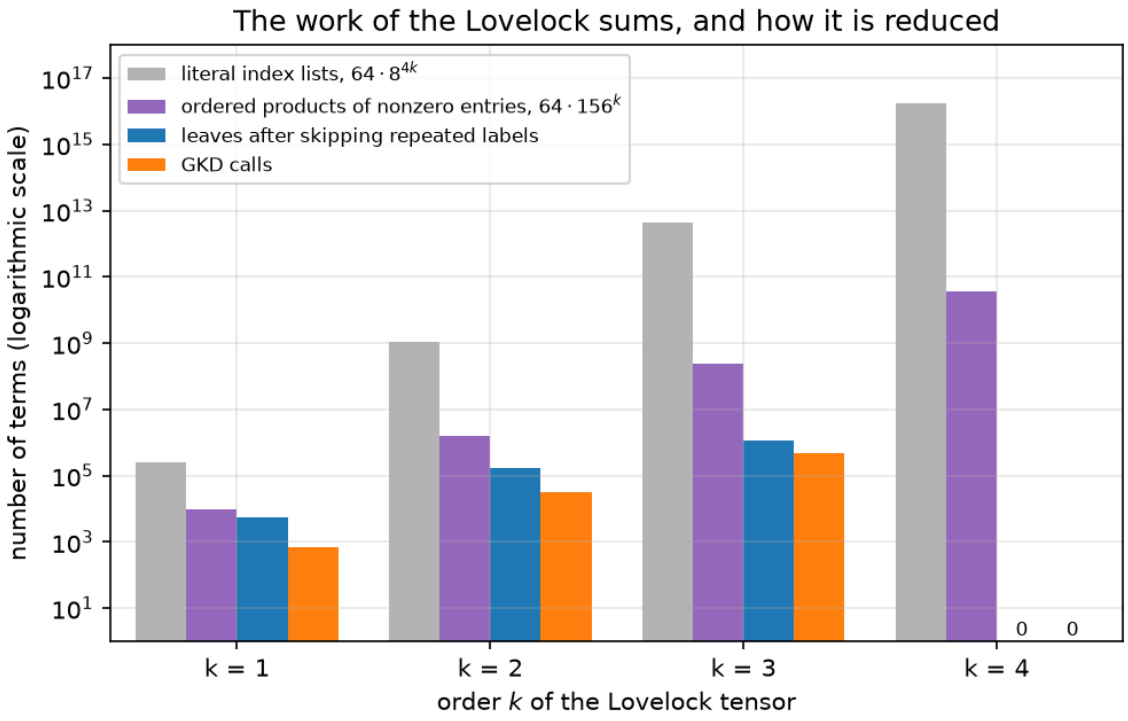

Figure 309: The number of terms of the Lovelock sums for the 64 components of $P_{(k)}$, order $k = 1$ to 4, on a logarithmic vertical axis: all index lists of the literal formula (grey), the ordered products of k of the 156 nonzero curvature entries (purple), the combinations left after skipping those with a repeated label (blue), and the ones for which GKD is called (orange). For $k = 3$ the literal sum has about 4.4×10^{12} terms, of which only 495,360 are evaluated; for $k = 4$ nothing is left, because nine labels out of eight must repeat. (Notebook 11b, figure 1.)

## 7. The Riemann tensor, recomputed with sympy

The next two cells compute the curvature of the metric of section 4 with sympy, from
the formulas of section 4, without using anything of the Rust program. The first one
defines the metric and its Christoffel symbols. ‘sp.Function("a4")(x4)‘ and
‘sp.Function("b4")(x4)‘ are unknown functions of the time; ‘sp.diff‘
differentiates exactly. Because the metric is
diagonal, the formula $\Gamma^a{}_{bc} = \tfrac12 g^{aa}(\partial_b g_{ac} +
\partial_c g_{ab} - \partial_a g_{bc})$ has at most three terms, each present only
when two of the labels $a, b, c$ are equal; the cell adds exactly those and keeps the
symbols that are not zero in the dictionary ‘christoffel‘.
```

In [6]:

```
import sympy as sp  # exact algebra and calculus

H = sp.Symbol("H", positive=True)  # the author's constant H > 0
X = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7
a4 = sp.Function("a4")(X[4])  # the unknown function a4(x4)
b4 = sp.Function("b4")(X[4])  # the unknown second function b4(x4) > 0
z = 6 * H * X[0]  # z = 6 H x0
warp = sp.sin(z) ** sp.Rational(1, 3)  # sin(z)^(1/3)
METRIC = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * warp] * 3 + [sp.Integer(-1)]
          + [-sp.exp(-2 * a4) * b4 * warp] * 3)  # g_00, g_11, ..., g_77

Text cell:

```
The next cell reads the 156 components that the Rust program wrote into
‘curvature.json‘ (as Mathematica text such as
‘H*Derivative[1][a4][x4]*Cot[6*H*x0]^(-1)‘), turns each into a sympy expression by
replacing the Mathematica names with ‘A1‘, ‘A2‘, ‘B0‘, ‘B1‘, ‘B2‘, ‘C‘ and ‘^‘ with
‘**‘, and checks that the two computations give the same nonzero components with
EXACTLY the same values (‘sp.simplify(mine - theirs) == 0‘), for a general $b_4$.
It also checks the antisymmetry
$R^{ab}{}_{cd} = -R^{ba}{}_{cd} = -R^{ab}{}_{dc}$, the number of Christoffel symbols
and the Ricci scalar $R = \sum_{a,b} R^{ab}{}_{ab}$.

From here on the notebook works on the background $b_4 = 1$ of the Revision records
($b_4' = b_4'' = 0$): ‘RIEMANN‘ now holds the 156 components there, and
‘RIEMANN_B4‘ keeps those with a general $b_4$.

The next cell draws the curvature of every coordinate plane, $K(a, b) =
R^{ab}{}_{ab}$, as two $8 \times 8$ tables of coloured squares, in units of $H^2$
(that is, with $H = 1$). The left table is a moment of the exponentially deflating
history $a_4 = A H x_4$ with $A = 2$, so $a_4' = 2H$ and $a_4'' = 0$; the right
table has the same $a_4'$ and $a_4'' = H^2$. The function ‘value_at‘ puts numbers in
place of the symbols (‘expr.subs(...)‘), and ‘float‘ turns the exact result into a
decimal number. The table is symmetric, $K(a, b) = K(b, a)$. Reading it: inside
ordinary space and inside the extra times $K = a_4'^2 - H^2$; between them
$K = -(a_4'^2 + H^2)$; with the time $x_4$, $K = a_4'^2 + a_4''$ for ordinary space
and $a_4'^2 - a_4''$ for the extra times; with the hidden direction $x_0$,
$K = -H^2$; the time and the hidden direction together are flat.
```

```
Figure 11b.3 saved as Revision/textbook/figures/11b_3_riemann_matrix.png
PASS 156 of the 4096 components are not zero at this point
```

Text cell:

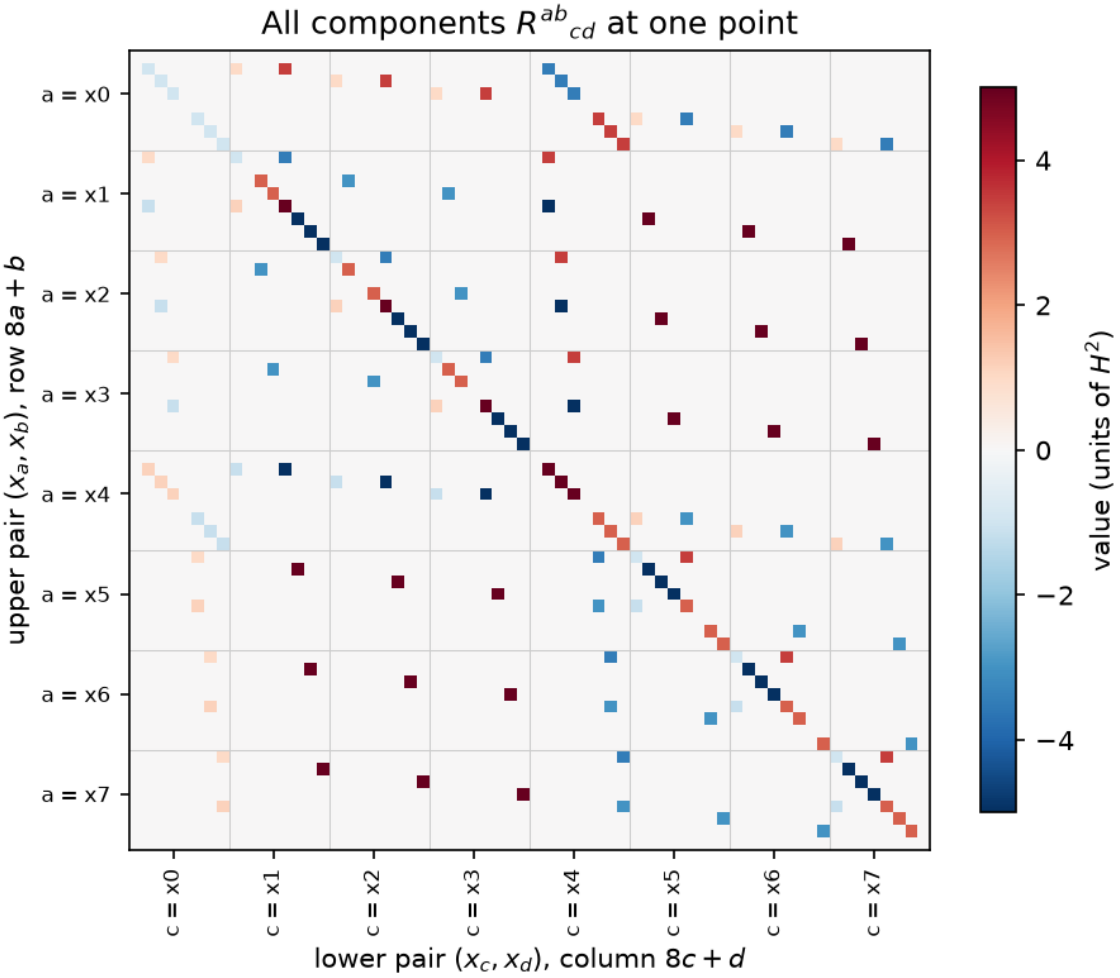

Figure 311: All 4096 components of the Riemann tensor $R^{ab}{}_{cd}$ of the author's metric at the point $H = 1$, $a_4' = 2$, $a_4'' = 1$, $z = \pi/3$, arranged as a 64 by 64 table: row $8a + b$ is the upper pair of labels, column $8c + d$ the lower pair, counted from 0; red is positive, blue negative, white zero. Only 156 components are not zero. The two diagonals hold the curvatures of the coordinate planes and their sign-reversed copies; the scattered squares between them mix the time x_4 with the hidden direction x_0. (Notebook 11b, figure 3.)

```
Why do the mixed $x_4$-$x_0$ terms not enter Einstein's tensor? The Ricci component
$R^{x_4}{}_{x_0} = \sum_c R^{x_4 c}{}_{x_0 c}$ adds one term for each direction $c$.
The next cell lists these seven terms: each of the three space directions gives
$+H a_4' \cot z$, each of the three extra times $-H a_4' \cot z$, and the hidden
direction itself gives 0. The sum vanishes EXACTLY, for every $a_4$, because there
are as many inflating as deflating directions, on the background $b_4 = 1$. With
a changing $b_4$ the three extra-time terms carry an additional piece with $b_4'$,
and the cell checks that the sum is then $R^{x_4}{}_{x_0} = \tfrac32 H\cot z\,
b_4'/b_4$, the mixed component of the Einstein tensor in the record (`einsteinMixed`
of `curvature.json`): with $b_4' \neq 0$ the time and the hidden direction DO mix.
The cell draws the seven terms at the point $H = 1$, $a_4' = 1$, $z = \pi/4$
($\cot z = 1$), $b_4 = 1$.

```
## 8. The three Lovelock tensors with a Python GKD sum
```

The next cell prepares the exact arithmetic, on the background $b_4 = 1$. A polynomial in H, A_1, A_2, C is
stored as a Python dictionary that maps the exponents $(e_H, e_{A_1}, e_{A_2}, e_C)$ of a monomial to its coefficient, a ‘Fraction‘ (an exact fraction of whole numbers); e_C may be negative. ‘poly_mul‘ multiplies two polynomials (every monomial of the first by every monomial of the second, adding the exponents), ‘poly_add‘ adds a multiple of one polynomial to another, dropping monomials whose coefficient becomes 0. ‘to_poly‘ turns a sympy expression into this form (‘sp.Poly‘ lists the monomials of ‘expr * C**8‘; the factor C^8 makes every power of C positive, and 8 is then subtracted again). The 156 nonzero entries $R^{ab}{}_{cd}$ of the sympy computation of section 7, sorted by their labels, become the list ‘ENTRIES‘.

The cell also defines ‘gkd‘, the rule of Notebook 11a: the sign of the permutation that carries the lower list into the upper list, or 0. In a term of the sum the UPPER labels a, b of an entry $R^{ab}{}_{cd}$ go into the LOWER list of the delta and its lower labels c, d into the upper list (look at the formula of section 4). The cell stores both pairs of every entry as **bit masks**: a set of labels is written as the whole number $\sum 2^{\text{label}}$, so that two sets share a label exactly when the bitwise AND (‘&‘) of their numbers is not 0, and the union of two sets is the bitwise OR (‘|‘). ‘np.array‘ holds the 156 masks, so that one comparison tests all 156 entries at once.

```

Text cell:

```
The next cell defines ‘lovelock_sum(k, free_pair)‘, the sum of section 4. It works
with a list ‘stack‘ of partial combinations: each holds the chosen entries (their
numbers in ‘ENTRIES‘) and the masks of the labels used so far in the lower and in
the upper list. A partial combination with fewer than $k$ entries is extended by
every entry that shares no label with it, in the lower list or in the upper list
(‘np.nonzero‘ finds them among all 156 at once); this is the skipping of repeated
labels. A complete combination (a **leaf**) is kept only if its lower and upper
label sets are equal (otherwise some lower label is missing above and GKD is 0);
then GKD is called on the lower list $(j, j_1, \dots, j_{2k})$ and the upper list
$(h, h_1, \dots, h_{2k})$, and its value is added to the weight of the combination.
The weights are collected per SET of entries (‘tuple(sorted(...))‘), because the
product of the entries does not depend on their order; at the end every set’s
product is multiplied out once. With ‘free_pair=True‘ the sum is done for each of
the 64 pairs $(h, j)$ and gives the tensor $P_{(k)}{}^h{}_j$; with ‘free_pair=False‘
it gives the scalar $L_{(k)}$. The function also counts leaves and GKD calls.
```

In [13]:

```
def lovelock_sum(k, free_pair):
    """P_(k) as {(h, j): polynomial} (free_pair True) or L_(k) as {None: polynomial},

```

Text cell:

```
The next cell compares every one of the $3 \times 64$ components with the Rust
record `lovelock-tensors.json`, which stores each component, for a general $b_4$, as
an exact list of monomials `[numerator, denominator, [e_H, e_a4', e_a4'', e_a4''',
e_a4'''', e_E, e_S, e_C, e_Q, e_b4', e_b4'', e_b4''', e_b4''']]` (E is $e^{a_4}$,
S is $\sin^{1/3} z$, C is $\cot z$, Q is $b_4^{1/2}$). The record is evaluated on
the background $b_4 = 1$: a monomial with a derivative of $b_4$ is dropped, and
$Q = 1$ (monomials that then agree are added). The comparison is exact
(dictionaries of fractions must be equal). The components of the third and fourth
derivatives of $a_4$, of $E$ and of $S$ must all be 0. Then it compares the three
scalars with the record's `L1`, `L2`, `L3`, and prints the components that are not
zero: only the eight diagonal ones $h = j$, for every $k$. In particular there is no
$x_4$-$x_0$ component.

```
**The skipping changes nothing: the literal sums of orders 1 and 2.** The sums
above leave out every combination in which a label repeats, because GKD is 0 there
(Notebook 11a). The next cell does NOT rely on this. For $k = 1$ and $k = 2$ it
runs through EVERY ordered list of $k$ of the 156 nonzero entries
(‘itertools.product(range(156), repeat=k)‘ gives all $156^k$ of them), builds the
lower list $(j_1, \dots, j_{2k})$ and the upper list $(h_1, \dots, h_{2k})$ of the
delta, and calls GKD for the scalar and for each of the 64 pairs $(h, j)$, with no
test before the call: $65 \cdot 156 = 10140$ calls for $k = 1$ and
$65 \cdot 156^2 = 1581840$ calls for $k = 2$, the numbers recorded by the Revision’s
sympy checker for the same literal sums. The weights are collected per set of
entries as before, the products are multiplied out, and the results must equal the
tensors and scalars of the skipping sums EXACTLY. The cell takes about 15 seconds.
```

Text cell:

```
**Order 4 is zero.** A term of $P_{(4)}$ needs four curvature entries, that is nine
labels in each list. The next cell looks at the leaves of order 3: every one of them
already uses seven DIFFERENT labels in its lower list ($j$ and six more), so a
fourth entry, which brings two new labels, would need nine different labels out of
eight. No leaf of order 4 exists, which is the Rust counter ‘leaves = 0‘ for
$k = 4$. (‘bin(mask).count("1")‘ counts the labels in a mask.) The scalar $L_{(4)}$,
with eight labels per list, is NOT zero (the program printed it in section 5); it is
the Euler density of eight dimensions, and its tensor $P_{(4)}$ vanishes
identically.
```

```
## 9. Three classical identities, and the traces

**Order 1 is Einstein's tensor, derived line by line.** Expand the $3 \times 3$
determinant $\delta^{h h_1 h_2}_{j j_1 j_2}$ along its column of $h$ (rows belong to
the lower labels $j, j_1, j_2$, columns to the upper labels $h, h_1, h_2$):

$$\delta^{h h_1 h_2}_{j j_1 j_2} = \delta^h_j\, \delta^{h_1 h_2}_{j_1 j_2}
  - \delta^h_{j_1}\, \delta^{h_1 h_2}_{j j_2} + \delta^h_{j_2}\,
  \delta^{h_1 h_2}_{j j_1}.$$

(Each term is an entry of the column times the $2 \times 2$ determinant left when
its row and the column are removed, with the signs $+, -, +$.) Multiply by
$R^{j_1 j_2}{}_{h_1 h_2}$ and sum. Since $\delta^{h_1 h_2}_{j_1 j_2} =
\delta^{h_1}_{j_1}\delta^{h_2}_{j_2} - \delta^{h_2}_{j_1}\delta^{h_1}_{j_2}$, the
first term gives $\delta^h_j (R^{h_1 h_2}{}_{h_1 h_2} - R^{h_2 h_1}{}_{h_1 h_2})
= 2R\,\delta^h_j$ (antisymmetry, and $\sum R^{ab}{}_{ab} = R$). The second gives
$-(R^{h j_2}{}_{j j_2} - R^{h j_2}{}_{j_2 j}) = -2 R^h{}_j$. The third gives
$R^{j_1 h}{}_{j j_1} - R^{j_1 h}{}_{j_1 j} = 2 R^{j_1 h}{}_{j j_1} = -2 R^h{}_j$.
Together

$$P_{(1)}{}^h{}_j = 2R\,\delta^h_j - 4 R^h{}_j = -4\big(R^h{}_j - \tfrac12 R\,
  \delta^h_j\big) = -4\, G^h{}_j,$$

and in the same way $L_{(1)} = \delta^{h_1 h_2}_{j_1 j_2} R^{j_1 j_2}{}_{h_1 h_2} =
2R$.

**Order 2 is the Gauss-Bonnet tensor.** The same expansion, done twice, gives
$P_{(2)} = -8\,\mathcal{H}$ and $L_{(2)} = 4\,\mathrm{GB}$, with the Gauss-Bonnet
scalar $\mathrm{GB} = R^2 - 4 R^a{}_b R^b{}_a + R^{ab}{}_{cd} R^{cd}{}_{ab}$ and
Lanczos's tensor
$2\mathcal{H}^h{}_j = 4\big(R R^h{}_j - 2 R^h{}_a R^a{}_j - 2 R^{ha}{}_{jb} R^b{}_a
+ R^{ha}{}_{bc} R^{bc}{}_{ja}\big) - \delta^h_j\, \mathrm{GB}$ (the derivation is
written out in the Revision checker `check_lovelock_gkd.py`, which also confirmed the
factors $-4$ and $-8$ on random curvature tensors).
```

```
**Order 3 is the cubic Lovelock density.** $L_{(3)} = 8\,(2T_1 + 8T_2 + 24T_3 + 3T_4
+ 24T_5 + 16T_6 - 12T_7 + T_8)$ with the eight cubic invariants
$T_1 = R^{ab}{}_{cd}R^{cd}{}_{ef}R^{ef}{}_{ab}$,
$T_2 = R^{ab}{}_{cd}R^{ce}{}_{bf}R^{df}{}_{ae}$,
$T_3 = R^{ab}{}_{cd}R^{cd}{}_{be}R^e{}_a$,
$T_4 = R\,R^{ab}{}_{cd}R^{cd}{}_{ab}$,
$T_5 = R^{ab}{}_{cd}R^c{}_aR^d{}_b$,
$T_6 = R^a{}_bR^b{}_cR^c{}_a$, $T_7 = R\,R^a{}_bR^b{}_a$, $T_8 = R^3$ (the
coefficients were derived by the Revision checker from 9 random curvature tensors).

The next three cells compute, from ‘ENTRIES‘ and with the exact polynomial
arithmetic, the Ricci tensor, the Ricci scalar and Einstein’s tensor; then the
Gauss-Bonnet scalar and tensor; then the eight cubic invariants; and each checks its
identity for all 64 components. The first cell checks order 1. ‘RM‘ is the
dictionary of the entries, ‘get(key, {})‘ gives the empty polynomial (zero) for a
missing key, ‘poly_sum‘ adds a list of polynomials, and ‘delta[h, j]‘ is the
polynomial 1 for $h = j$ and 0 otherwise.
```

In [18]:

```

Text cell:

```
**The expansion along the column of $h$, for every order (derived line by line).**
The delta of $P_{(k)}$ is the determinant of a $(2k + 1) \times (2k + 1)$ matrix
whose rows belong to the lower labels $j, j_1, \dots, j_{2k}$ (in this order) and
whose columns belong to the upper labels $h, h_1, \dots, h_{2k}$. Expand it along
its first column, the column of $h$ (Laplace's rule, section 3).

1. The first entry of the column is $\delta^h_j$, in row 1 and column 1: its sign
   is $(-1)^{1+1} = +1$, and its minor is $\delta^{h_1 \dots h_{2k}}_{j_1 \dots
   j_{2k}}$. Multiplied by the curvature factors and summed, it gives
   $\delta^h_j\, L_{(k)}$, by the definition of the scalar.
2. The entry in row $r + 1$ ($r = 1, \dots, 2k$) is $\delta^h_{j_r}$, with the sign
   $(-1)^{(r+1)+1} = (-1)^r$. Its minor has the rows $j, j_1, \dots, j_{r-1},
   j_{r+1}, \dots, j_{2k}$. Moving the row of $j$ down past the $r - 1$ rows
   $j_1, \dots, j_{r-1}$ is $r - 1$ exchanges of neighbouring rows, so the minor is
   $(-1)^{r-1}$ times the delta whose lower list is $j_1, \dots, j_{2k}$ with $j$
   in place $r$. The two signs give $(-1)^r (-1)^{r-1} = -1$.
3. The factor $\delta^h_{j_r}$ is 1 only for $j_r = h$, so the sum over $j_r$
   puts $h$ into the curvature factor that held $j_r$. Term $r$ is therefore
   $-\delta^{h_1 \dots h_{2k}}_{j_1 \dots j \dots j_{2k}} R \cdots R$, with $j$ in
   place $r$ of the delta and $h$ in place $r$ of the upper labels of the factors.
4. The $2k$ terms are equal. If $r$ is the second place of its factor
   $R^{j_{r-1} j_r}{}_{h_{r-1} h_r}$, exchange the rows $r - 1$ and $r$ of the
```

```
   delta (sign $-1$) and write $R^{j_{r-1} h}{}_{\dots} = -R^{h j_{r-1}}{}_{\dots}$
   (sign $-1$): the term is unchanged and $h$ stands first. If the factor is not
   the first one, exchange it with the first factor: the product of the factors is
   unchanged, and in the delta two pairs of rows and the two matching pairs of
   columns change places; each such exchange of two pairs is two exchanges of two
   rows (or columns), sign $(-1)^2 = +1$ for the rows and $+1$ for the columns.
   After renaming the summed labels every term is the term $r = 1$.
5. Hence, with $Y_{(k)}{}^h{}_j = \sum \delta^{h_1 \dots h_{2k}}_{j\, j_2 \dots
   j_{2k}}\, R^{h j_2}{}_{h_1 h_2} R^{j_3 j_4}{}_{h_3 h_4} \cdots
   R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}$,

$$P_{(k)}{}^h{}_j = \delta^h_j\, L_{(k)} - 2k\, Y_{(k)}{}^h{}_j .$$

For $k = 1$: $Y_{(1)}{}^h{}_j = \delta^{h_1 h_2}_{j j_2} R^{h j_2}{}_{h_1 h_2} =
R^{h j_2}{}_{j j_2} - R^{h j_2}{}_{j_2 j} = 2 R^h{}_j$, and $P_{(1)} = 2R\,\delta
- 4 R^h{}_j = -4G$, the result above. The next cell computes $Y_{(k)}$ for
$k = 1, 2, 3$ with GKD (the sum of section 8, with the first entry required to
carry the upper label $h$) and checks the expansion for all 64 components exactly.
```

In [21]:

**The trace identity.** Set $j = h$ in the expansion and sum over $h$. The first
term gives $\sum_h \delta^h_h\, L_{(k)} = 8\, L_{(k)}$ (eight values of $h$). In
$\sum_h Y_{(k)}{}^h{}_h$ the label $h$ is summed like $j_1$ in the definition of
the scalar; renaming it $j_1$ gives exactly $L_{(k)}$. So
$\sum_h P_{(k)}{}^h{}_h = 8 L_{(k)} - 2k\, L_{(k)} = (8 - 2k)\, L_{(k)}$. The next
cell checks it for $k = 1, 2, 3$, and prints the three scalars.
```

In [22]:

```
def show(p):
    """A polynomial dict as text, with a4' and a4'' written A1 and A2."""

## 10. The components of the three tensors at one moment

The field equations of $a_4$ (chapter 12) use the normalised tensors
$E_{(k)} = -P_{(k)}/2^{k+1}$ of section 4. The next cell draws all 64 components
of $E_{(1)}$ (Einstein's tensor $G$), $E_{(2)}$ and $E_{(3)}$ as three
$8 \times 8$ tables, at the moment $a_4' = 2H$, $a_4'' = H^2$ of a deflating
history (the same moment as the right table of the plane curvatures), in units of
$H^2$, $H^4$ and $H^6$ (that is, with $H = 1$). Each square shows the number of row
$h$ and column $j$; red is positive, blue negative, white zero, and each table has
its own colour scale (its largest value is the darkest colour). The tables show what
sections 7 and 8 proved: only the diagonal is filled, the $x_4$-$x_0$ squares are
zero, the three space entries are equal, the three extra-time entries are equal,
and the hidden entry $x_0$ lies halfway between the space and the extra-time entry.
```

## 11. The Revision records quoted in this notebook

This notebook quotes check names and numbers from the Revision records. The four
result files of the Rust program were compared in full in section 5 (byte for byte),
and its counters in sections 6 and 8. The next cell reads the two verification
```

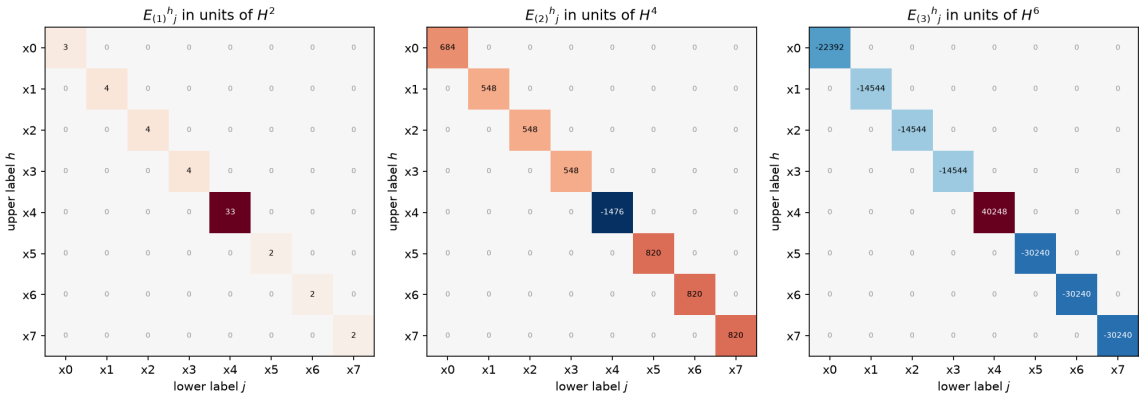

Figure 313: All 64 components $E_{(k)}{}^{h}{}_{j}$ of the normalised Lovelock tensors $E_{(1)} = G$ (left), $E_{(2)}$ (middle) and $E_{(3)}$ (right) of the author's metric at the moment $a_4' = 2H$, $a_4'' = H^2$ of a deflating history, in units of H^2, H^4 and H^6; row h, column j; red positive, blue negative, white zero, each table on its own colour scale. Only the diagonal is filled, so the x_4-x_0 components vanish; the three space entries are equal, the three extra-time entries are equal, and the hidden entry is their mean, for example $(4 + 2)/2 = 3$ for Einstein's tensor. (Notebook 11b, figure 5.)

```
reports once more and checks the rest of what the text quotes, so that a later
change of a record cannot pass unnoticed:

- every check quoted from the sympy verification ‘python-lovelock-report.json‘ and
  from the Rust report ‘lovelock-report.json‘ is present with the verdict PASS;
- the sympy verification has 49 checks and the Wolfram verification
  ‘wolfram-gkd-report.json‘ has 29 checks, none of them failed, as section 4 says.

The function ‘verdicts(path)‘ returns, for one report, a dictionary from the name of
each check to its verdict. The reports store their checks in one of two forms: a
list of entries, each with a ‘name‘ and a ‘verdict‘, or a dictionary from the name to
an entry whose field ‘passed‘ is true or false; the function reads both.
```

In [24]:

```

```

Text cell:

```
## 12. What this notebook showed

- The Revision Rust program ‘lovelock_gkd‘, built here, computed the curvature and
  the three Lovelock tensors of the author’s metric, passed its 19 checks (including
  the literal unpruned sums of orders 1 and 2), and wrote its four result files
  again, byte for byte equal to the Revision records.
- The Riemann tensor, recomputed independently with sympy, has the same 156 nonzero
  components; they depend only on $H$, $a_4’$, $a_4’’$ and $\cot z$. Planes inside
  ordinary space or inside the extra times have the curvature $a_4’^2 - H^2$, planes
  between them $-(a_4’^2 + H^2)$, planes with the hidden direction $-H^2$.
- The mixed $x_4$-$x_0$ curvature terms of the three inflating and the three
  deflating directions cancel exactly.
- Pruning (only nonzero curvature entries, no repeated labels) reduces the sum of
  order 3 from about $4.4 \times 10^{12}$ terms to 495,360 GKD calls; a Python
  implementation of the same plan, written independently, reproduces every counter
  of the Rust program and all $3 \times 64$ components and the three scalars exactly.
  The literal sums of orders 1 and 2, with GKD called on every one of 10,140 and
  1,581,840 index lists and nothing skipped, give the same tensors: the skipping
  changes nothing.
- Every Lovelock tensor expands along the column of its free upper label as
  $P_{(k)} = \delta\, L_{(k)} - 2k\, Y_{(k)}$ (derived line by line and checked
  exactly for $k = 1, 2, 3$); for $k = 1$ this gives Einstein’s tensor, and for
  every $k$ the trace identity $\sum_h P_{(k)}{}^h{}_h = (8 - 2k) L_{(k)}$.
- Only the eight diagonal components of each Lovelock tensor are nonzero; at a
  moment of a deflating history the three space entries are equal, the three
```

```
  extra-time entries are equal and the hidden entry is their mean. Order 1 is
  $-4$ times Einstein's tensor, order 2 is $-8$ times the Gauss-Bonnet tensor, the
  third scalar is 8 times the cubic Lovelock density, and $P_{(4)} = 0$ (PROVED by
  exact computation).
- Every check that the notebook quotes from the Revision verifications is present in
  them with the verdict PASS, and the sympy and Wolfram verifications have 49 and 29
  checks, none of which failed.
```

11.19 Line-by-line walk-through of Notebook 11b

The notebook has 25 code cells, In [1] to In [25]. As in Section 11.9, every line or small group of lines is quoted and explained; docstrings are left out where the explanation repeats them, and long captions are shortened to `...` (they are printed in full under the figures in Section 11.18).

In [1], the set-up cell. It is word for word the set-up cell of Notebook 11a, explained line by line in Section 11.9 under In [1], with two differences: its comment lines are the run instructions of Notebook 11b (Section 11.17), and its line `NOTEBOOK_ID = "11b" # this notebook: chapter 11, example b` names this notebook, so the figures are saved as `11b_<k>_<name>.png` and their captions in `11b.captions.json`. It contains the helper `rust_program`. It prints Set-up of notebook 11b complete: repository folder found, helpers defined.

In [2], the Rust program is built.

```
program = rust_program("Revision/gkd_lovelock/code/Cargo.toml", "lovelock_gkd")
```

The same line as In [13] of Notebook 11a: cargo builds the crate (or confirms in about a second that it is up to date), and `program` is the path of `lovelock_gkd`. Output: Rust program lovelock_gkd is built and ready.

In [3], the program computes everything. The command it runs is

```
lovelock_gkd lovelock --output FOLDER --brute-force-k2
```

with the option that adds the literal unpruned sum of order 2 at a numerical point (Section 11.12).

```
import re  # regular expressions: patterns that read parts of a line of text

RESULTS = "Revision/gkd_lovelock/results"  # the folder of the Revision records
OUT_FOLDER = REPO / "Revision" / "gkd_lovelock" / "code" / "target" / "textbook_11b"
completed = subprocess.run(
    [str(program), "lovelock", "--output", str(OUT_FOLDER), "--brute-force-k2"],
    capture_output=True, text=True, encoding="utf-8", errors="replace")
```

The module `re` reads parts of the printed lines. `RESULTS` is the folder of the Revision records, and `OUT_FOLDER` a folder inside the crate's build folder `target`, which git ignores, so the run adds nothing to the repository. `subprocess.run` starts the program and collects what it prints (Section 11.9, In [1] and In [14]). The program computes, exactly and from the metric alone, the Christoffel symbols, the Riemann tensor and the Lovelock tensors of orders 1 to 4, runs its 19 checks and writes four files; this takes about 15 seconds.

```
rust_checks = []  # (name, verdict) of every check the program printed
for line in completed.stdout.splitlines():
    found = re.match(r"(PASS|FAIL) - (\w+): ", line)
    if found:
        rust_checks.append((found.group(2), found.group(1)))
    if line.startswith("info - L_(4)"):
        l4_text = line.split("): ", 1)[1]  # the formula after the explanation
```

Each printed line is examined. `re.match` tests whether the line BEGINS with the pattern: PASS or FAIL (`(PASS|FAIL)` means one or the other), a dash, and a name made of letters, digits and underscores (`\w+`), followed by a colon. `found.group(2)` is the name and `found.group(1)` the verdict; the pair is stored. The program also prints an information line with the scalar $L_{(4)}$; `line.split("): ", 1)` cuts that line once at the first `):` and `[1]` keeps the part after it, the formula.

```
say("The checks of the Rust program (name, verdict):")
for number, (name, verdict) in enumerate(rust_checks, 1):
    say(f"  {number:2d} {name:34s} {verdict}")
```

The 19 checks are printed as a numbered table (the format `:34s` pads a text to 34 places). They are: the antisymmetry and the first Bianchi identity of the Riemann tensor, the freedom of every $R^{ab}{}_{cd}$ from $\sin^{1/3} z$, the identity $P_{(1)} = -4G$; for each order $k = 1, 2, 3$ the trace identity, zero divergence, symmetry and freedom from $\sin^{1/3} z$; the vanishing of $P_{(4)}$; and the two brute-force sums. All 19 print PASS.

```
readable = (l4_text.replace("Derivative[1][a4][x4]", "a4'").replace("*", " ")
            .replace("(", "").replace(")", ""))
report("eighth-order scalar printed by the program, L(4)", readable)
```

The program writes a_4' in Mathematica's notation `Derivative[1][a4][x4]`; the chain of `replace` calls turns it into `a4'`, multiplication stars into blanks, and removes parentheses. The RESULT line prints $L_{(4)} = -663552H^2a_4'^6 - 442368H^4a_4'^4 - 663552H^6a_4'^2$, the nonzero Euler density of Section 11.11.

```
check(completed.returncode == 0 and "lovelock: SUCCESS" in completed.stdout,
      "the Rust program lovelock_gkd lovelock ended with SUCCESS")
check(len(rust_checks) == 19 and all(v == "PASS" for _, v in rust_checks),
      "all 19 checks of the Rust program passed",
      record=f"{RESULTS}/lovelock-report.json, checkCount 19, failedCheckCount 0")
```

Two checks: the program ended with the return code 0 and the verdict SUCCESS, and it printed exactly 19 checks, all PASS, as the record states. PASS lines one and two.

In [4], the four files against the records.

```
DEVIATION = re.compile(r"(max relative deviation from the exact P_\(\d\) = )"
                       r"([0-9.]+e[-+]?\d+)")  # the two floating-point numbers
```

`re.compile` prepares a pattern for repeated use. It finds the text "max relative deviation from the exact P_(1) = " (or P_(2); `\d` is one digit, `\(` and `\)` literal parentheses) as the first group, and the decimal number that follows as the second group: digits and points, the letter e, an optional sign and digits, for example `1.40e-15`.

```
for file_name in ("curvature.json", "lovelock-tensors.json",
                  "lovelock-components.md"):
    written = (OUT_FOLDER / file_name).read_bytes()
    stored = repository_file(f"{RESULTS}/{file_name}").read_bytes()
    report(f"size of {file_name}", len(written), "bytes")
    check(written == stored,
          f"the program wrote {file_name} equal to the Revision record byte for byte",
          record=f"{RESULTS}/{file_name} (the whole file)")
```

The three files that hold only exact numbers are compared with the committed records byte for byte, and their sizes are printed: 28,162, 55,056 and 19,604 bytes. PASS lines three to five.

```
written = (OUT_FOLDER / "lovelock-report.json").read_text(encoding="utf-8")
stored = repository_file(f"{RESULTS}/lovelock-report.json").read_text(
    encoding="utf-8")
deviations = [float(number) for _, number in DEVIATION.findall(written)]
masked_written = DEVIATION.sub(r"\1X", written)  # the two numbers replaced by X
masked_stored = DEVIATION.sub(r"\1X", stored)
```

The report holds two decimal numbers, the rounding errors of the two brute-force checks, whose last digits may depend on the mathematics library of the operating system. `DEVIATION.findall(written)` finds both, and `float` turns the second group of each into a decimal number. `DEVIATION.sub(r"\1X", ...)` replaces every match by its first group followed by the letter X, so the two numbers disappear from both texts.

```
report("size of lovelock-report.json", len(written.encode("utf-8")), "bytes")
check(masked_written == masked_stored and len(deviations) == 2
      and all(value < 1e-10 for value in deviations),
      "the program wrote lovelock-report.json equal to the Revision record byte for "
      "byte, apart from its two brute-force deviations, both below 1e-10",
      record=f"{RESULTS}/lovelock-report.json (the whole file; checks "
             "k1_brute_force_numeric and k2_brute_force_numeric)")
```

The size is printed (3,154 bytes). The check requires the masked texts to be equal, exactly two deviations, and both below the program's own limit 10^{-10}. (On the computer that built the book the file was equal byte for byte even without the masking.) Sixth PASS line.

In [5], the work of the sums (Figure 11b.1).

```
import numpy as np  # arrays of numbers

lovelock_report = json.loads((OUT_FOLDER / "lovelock-report.json").read_text(
    encoding="utf-8"))
COUNTERS = {row["k"]: row for row in lovelock_report["counters"]}
```

The report just compared is read as JSON; its field `counters` is a list of four rows, one per order, and the dictionary comprehension stores each row under its order k.

```
say("order k   literal lists   ordered products    leaves   GKD calls   nonzero GKD")
for k in (1, 2, 3, 4):
    leaves, calls = COUNTERS[k]["leaves"], COUNTERS[k]["gkdCalls"]
    nonzero = COUNTERS[k]["gkdNonzero"]
    say(f"      {k}   {64 * 8 ** (4 * k):13.2e}   {64 * 156 ** k:16.2e}   "
        f"{leaves:7d}   {calls:9d}   {nonzero:11d}")
```

A table of Section 11.12: for each order the literal number $64 \cdot 8^{4k}$ of index lists, the number $64 \cdot 156^k$ of ordered products of nonzero entries, and the record's leaves, GKD calls and nonzero GKD values. The output shows 5616, 176640, 1128960, 0 leaves and 696, 32640, 495360, 0 calls, each call nonzero.

```
fig, ax = plt.subplots(figsize=(7.6, 4.5))
orders = np.array([1, 2, 3, 4])
series = [("literal index lists, $64 \\cdot 8^{4k}$", [64 * 8 ** (4 * k)
                                                       for k in orders], "0.7"),
          ("ordered products of nonzero entries, $64 \\cdot 156^k$",
           [64 * 156 ** k for k in orders], "tab:purple"),
          ("leaves after skipping repeated labels",
           [COUNTERS[k]["leaves"] for k in orders], "tab:blue"),
          ("GKD calls", [COUNTERS[k]["gkdCalls"] for k in orders], "tab:orange")]
```

The four series of bars, each a name for the legend, four heights and a colour.

```
width = 0.2
for number, (name, heights, colour) in enumerate(series):
    place = orders + (number - 1.5) * width
    ax.bar(place, [h if h > 0 else np.nan for h in heights], width, color=colour,
           label=name)
    for x, h in zip(place, heights):
        if h == 0:
            ax.text(x, 1.5, "0", ha="center", fontsize=8)
```

Each series is shifted sideways by its own amount (adding a number to the numpy array `orders` adds it to every entry). A height 0 is drawn as `np.nan` ("not a number", which matplotlib leaves out), because 0 has no place on a logarithmic axis, and a small "0" is written instead.

```
ax.set_yscale("log")
ax.set_ylim(1.0, 1e18)
ax.set_xlim(0.5, 4.5)
ax.set_xticks(orders, [f"k = {k}" for k in orders])
ax.set_xlabel("order $k$ of the Lovelock tensor")
ax.set_ylabel("number of terms (logarithmic scale)")
ax.set_title("The work of the Lovelock sums, and how it is reduced")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "work_of_the_sums",
            "The number of terms of the Lovelock sums for the 64 components of "
            ...)
```

A logarithmic vertical axis from 1 to 10^{18}, the marks, titles, legend, and the saved figure.

```
check([COUNTERS[k]["leaves"] for k in (1, 2, 3, 4)] == [5616, 176640, 1128960, 0]
      and [COUNTERS[k]["gkdCalls"] for k in (1, 2, 3, 4)] == [696, 32640, 495360, 0],
      "the counters of the Rust sums are 5616, 176640, 1128960, 0 leaves and 696, "
      "32640, 495360, 0 GKD calls")
```

The check fixes the counters quoted in the text. Seventh PASS line.

What Figure 11b.1 shows. For each order four bars on a logarithmic axis: grey (all literal index lists), purple (ordered products of nonzero curvature entries), blue (leaves without a repeated label) and orange (GKD calls). For $k = 3$ the grey bar reaches 4.4×10^{12} while the orange one stays at 495,360, about one term in nine million. For $k = 4$ the blue and orange bars are missing (marked 0): no leaf exists, because nine labels out of eight must repeat.

In [6], the metric and its Christoffel symbols with sympy.

```
import sympy as sp  # exact algebra and calculus

H = sp.Symbol("H", positive=True)  # the author's constant H > 0
X = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7
a4 = sp.Function("a4")(X[4])  # the unknown function a4(x4)
b4 = sp.Function("b4")(X[4])  # the unknown second function b4(x4) > 0
z = 6 * H * X[0]  # z = 6 H x0
warp = sp.sin(z) ** sp.Rational(1, 3)  # sin(z)^(1/3)
```

`sp.Symbol` makes a symbol that sympy computes with exactly; `positive=True` tells sympy that $H > 0$. `sp.symbols("x0:8")` makes the eight symbols `x0` to `x7` (the range 0 to 7), stored in the tuple `X`, so `X[k]` is x_k: `X[4]` is x_4 and `X[0]` is x_0. `sp.Function("a4")(X[4])` and `sp.Function("b4")(X[4])` are unknown functions of x_4, which sympy can differentiate: the history a_4 and the second function b_4 of the author's metric of 2026-10-14. `sp.Rational(1, 3)` is the exact fraction $1/3$, so `warp` is $\sin^{1/3} z$.

```
METRIC = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * warp] * 3 + [sp.Integer(-1)]
          + [-sp.exp(-2 * a4) * b4 * warp] * 3)  # g_00, g_11, ..., g_77
```

The diagonal of the author's metric as a list of eight entries: a list multiplied by 3 repeats it three times, and `+` joins lists. So `METRIC[0]` is $\cot^2 z$, `METRIC[1]` to `METRIC[3]` are $e^{2a_4} \sin^{1/3} z$, `METRIC[4]` is -1, and `METRIC[5]` to `METRIC[7]` are $-e^{-2a_4} b_4 \sin^{1/3} z$.

```
christoffel = {}  # (a, b, c) -> Gamma^a_bc, only the nonzero ones
for a in range(8):
    for b in range(8):
        for c in range(8):
            value = 0
            if a == c:
                value += sp.diff(METRIC[a], X[b])  # d_b g_ac
            if a == b:
                value += sp.diff(METRIC[a], X[c])  # d_c g_ab
```

```
            if b == c:
                value -= sp.diff(METRIC[b], X[a])  # - d_a g_bc
            if value != 0:
                christoffel[a, b, c] = value / (2 * METRIC[a])  # times g^aa / 2
```

The Christoffel formula of Section 11.10 for a diagonal metric: $\partial_b g_{ac}$ is nonzero only for $c = a$, $\partial_c g_{ab}$ only for $b = a$, and $\partial_a g_{bc}$ only for $c = b$. The three `if` lines add exactly these terms (`sp.diff(f, x)` is the exact derivative of `f` with respect to `x`). A nonzero result is divided by $2g_{aa}$, which is the factor $\frac{1}{2}g^{aa}$, and stored under the key `(a, b, c)`.

```
def gamma(a, b, c):
    return christoffel.get((a, b, c), 0)

christoffel_b_le_c = [key for key in christoffel if key[1] <= key[2]]
report("nonzero Christoffel symbols Gamma^a_bc with b <= c", len(christoffel_b_le_c))
check(all(christoffel.get((a, c, b)) == value
          for (a, b, c), value in christoffel.items()),
      "Gamma^a_bc = Gamma^a_cb (symmetric in the lower labels)")
```

`gamma(a, b, c)` returns a symbol, or 0 when it is not stored. The list `christoffel_b_le_c` keeps the symbols with $b \le c$; there are 25 (RESULT line), the 25 of the record (Section 3.23). The check confirms the symmetry $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$. Eighth PASS line.

In [7], the Riemann tensor with sympy.

```
A1, A2, C = sp.symbols("A1 A2 C")  # a4', a4'' and cot(z)
B0, B1, B2 = sp.symbols("B0 B1 B2")  # b4, b4' and b4''
SYMBOLS = {sp.Derivative(a4, (X[4], 2)): A2, sp.Derivative(a4, X[4]): A1,
           sp.Derivative(b4, (X[4], 2)): B2, sp.Derivative(b4, X[4]): B1}
RIEMANN = {}  # (a, b, c, d) -> R^ab_cd in the symbols H, A1, A2, C
```

Three plain symbols stand for a_4', a_4'' and $\cot z$, and three more, `B0`, `B1` and `B2`, for b_4, b_4' and b_4''. The dictionary `SYMBOLS` says which derivative becomes which symbol (each second derivative is listed before the first, so that it is replaced before the first derivative inside it); b_4 itself becomes `B0` afterwards. `RIEMANN` will hold the nonzero components.

```
for a in range(8):
    for b in range(8):
        for c in range(8):
            for d in range(8):
                value = sp.diff(gamma(a, d, b), X[c]) - sp.diff(gamma(a, c, b), X[d])
                for e in range(8):
                    value += (gamma(a, c, e) * gamma(e, d, b)
                              - gamma(a, d, e) * gamma(e, c, b))
                if value == 0:
                    continue
```

The formula of Section 11.10 for $R^a{}_{bcd}$, for all $8^4 = 4096$ combinations of labels: two derivative terms and the sum over e of the two products. `continue` skips to the next combination when the result is exactly zero.

```
                value = sp.simplify((value / METRIC[b]).subs(SYMBOLS)
                                    .subs(b4, B0))  # R^ab_cd
                value = sp.expand(value.subs({sp.tan(z): 1 / C, sp.cot(z): C,
                                              sp.cos(z): C * sp.sin(z)}))
                if value != 0:
                    RIEMANN[a, b, c, d] = value
report("nonzero components R^ab_cd", len(RIEMANN))
```

Dividing by g_{bb} raises the second label: $R^{ab}{}_{cd} = R^{a}{}_{bcd}/g_{bb}$. `.subs(SYMBOLS)` puts `A1`, `A2`, `B1` and `B2` in place of the derivatives, `.subs(b4, B0)` puts `B0` in place of b_4, and `sp.simplify` simplifies (this takes most of the cell's fifteen seconds). Then $\tan z$, $\cot z$ and $\cos z$ are written with the symbol `C` ($\tan z = 1/C$, $\cos z = C \sin z$), and `sp.expand` multiplies out. The nonzero results are stored: 156 of them (RESULT line), as Section 11.10 counted.

```
check(all(v.free_symbols <= {H, A1, A2, B0, B1, B2, C} for v in RIEMANN.values()),
      "every R^ab_cd is a rational expression in H, a4', a4'', b4, b4', b4'' and "
      "cot z, free of sin(z)^(1/3) and e^a4",
      record=f"{RESULTS}/lovelock-report.json, check mixed_riemann_free_of_sin_third")
```

`v.free_symbols` is the set of symbols in a component; `<=` between two sets means "is contained in". If any component still contained x_0 (through $\sin z$) or x_4 (through e^{a_4}), the check would fail. Ninth PASS line.

In [8], sympy against the Rust record.

```
curvature = json.loads((OUT_FOLDER / "curvature.json").read_text(encoding="utf-8"))
NAMES = curvature["coordinates"]  # ["x0", ..., "x7"]

def from_mathematica(text):
    text = re.sub(r"Derivative\[(\d)\]\[a4\]\[x4\]", r"A\1", text)  # a4' -> A1
    text = re.sub(r"Derivative\[(\d)\]\[b4\]\[x4\]", r"B\1", text)  # b4' -> B1
    text = text.replace("b4[x4]", "B0")  # b4 -> B0
    text = text.replace("Cot[6*H*x0]", "C").replace("^", "**")
    return sp.sympify(text, locals={"H": H, "A1": A1, "A2": A2, "C": C, "B0": B0,
                                    "B1": B1, "B2": B2})
```

The program's file `curvature.json` is read; its list of coordinate names becomes `NAMES`. `from_mathematica` turns a component written in Mathematica's notation, for example `H*Derivative[1][a4][x4]*Cot[6*H*x0]^(-1)`, into a sympy expression: `re.sub` replaces `Derivative[1][a4][x4]` by `A1` and `Derivative[2][a4][x4]` by `A2` (the group `(\d)` captures the digit and `\1` puts it back), and in the same way the derivatives of b_4 by `B1` and `B2`; `b4[x4]` becomes `B0`, $\cot z$ becomes `C`, Mathematica's power sign `^` becomes Python's `**`, and `sp.sympify` reads the text with the seven names bound to our symbols.

```
rust_riemann = {}
for item in curvature["riemannMixedNonzero"]:
    a, b = (NAMES.index(name) for name in item["up"])
    c, d = (NAMES.index(name) for name in item["down"])
```

```
    rust_riemann[a, b, c, d] = from_mathematica(item["value"])
same_values = set(rust_riemann) == set(RIEMANN) and all(
    sp.simplify(RIEMANN[key] - rust_riemann[key]) == 0 for key in RIEMANN)
check(same_values, "sympy and Rust give the same 156 nonzero R^ab_cd exactly, "
      "with b4",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "check rust_riemann_agrees")
```

Each of the record's nonzero components carries its upper pair, its lower pair and its value; `NAMES.index(name)` turns a name into its number. The check requires the same set of label combinations (a set of the keys of a dictionary) and an exactly vanishing difference for every component. Tenth PASS line.

```
antisymmetric = all(sp.expand(v + RIEMANN.get((b, a, c, d), 0)) == 0 and
                    sp.expand(v + RIEMANN.get((a, b, d, c), 0)) == 0
                    for (a, b, c, d), v in RIEMANN.items())
check(antisymmetric, "R^ab_cd = -R^ba_cd = -R^ab_dc for all components",
      record=f"{RESULTS}/lovelock-report.json, check riemann_antisymmetry")
check(len(christoffel_b_le_c) == len(curvature["christoffelNonzero_b_le_c"]) == 25,
      "25 nonzero Christoffel symbols with b <= c, as in the record")
```

The antisymmetry of Section 11.10: each component plus the component with the upper pair exchanged, and plus the one with the lower pair exchanged, must vanish. The second check compares the number of Christoffel symbols with the record's list (`a == b == 25` tests both equalities). PASS lines eleven and twelve.

```
ricci_scalar = sp.expand(sum(RIEMANN.get((a, b, a, b), 0) for a in range(8)
                             for b in range(8)))
report("Ricci scalar R", ricci_scalar)
check(sp.simplify(ricci_scalar - from_mathematica(curvature["ricciScalar"])) == 0
      and sp.expand(ricci_scalar.subs({B0: 1, B1: 0, B2: 0}))
      == 6 * A1 ** 2 - 42 * H ** 2,
      "the Ricci scalar is R = 6 a4'^2 - 42 H^2 + 3 b4''/b4 - 3 a4' b4'/b4, as in the "
      "record (6 a4'^2 - 42 H^2 at b4 = 1)",
      record=f"{RESULTS}/curvature.json, ricciScalar")
# From here on: the background b4 = 1 (b4' = b4'' = 0) of the Revision records.
RIEMANN_B4 = RIEMANN  # the components with a general b4
BACKGROUND = {B0: 1, B1: 0, B2: 0}
RIEMANN = {key: sp.expand(value.subs(BACKGROUND)) for key, value in RIEMANN_B4.items()}
RIEMANN = {key: value for key, value in RIEMANN.items() if value != 0}
check(len(RIEMANN) == 156,
      "on the background b4 = 1 the same 156 components are nonzero")
```

$R = \sum_{a,b} R^{ab}{}_{ab}$, twice the sum of the 28 plane curvatures. The RESULT line prints `6*A1**2 - 3*A1*B1/B0 - 42*H**2 + 3*B2/B0`, and the check compares it with the record and requires $6a_4'^2 - 42H^2$ at $b_4 = 1$. Then the notebook turns to the background $b_4 = 1$ of the records: `RIEMANN_B4` keeps the components with a general b_4, `BACKGROUND` is the substitution $b_4 = 1$, $b_4' = b_4'' = 0$, and `RIEMANN` now holds the components there, dropping those that become 0 (none does: the second check requires the same 156). PASS lines thirteen and fourteen.

In [9], the plane curvatures (Figure 11b.2).

```
def value_at(expr, h=1.0, a1=2.0, a2=0.0, cot=1.0):
    return float(sp.sympify(expr).subs({H: h, A1: a1, A2: a2, C: cot}))
```

`value_at` puts numbers in place of the four symbols (by default $H = 1$, $a_4' = 2$, $a_4'' = 0$, $\cot z = 1$) and returns a decimal number; `sp.sympify` also accepts the plain 0 of a missing component.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 5.0))
planes = {}
for ax, a2 in zip(axes, (0.0, 1.0)):
    table = np.array([[value_at(RIEMANN.get((a, b, a, b), 0), a2=a2)
                       for b in range(8)] for a in range(8)])
    planes[a2] = table
    picture = ax.imshow(table, cmap="RdBu_r", vmin=-6, vmax=6)
```

Two panels, for $a_4'' = 0$ and $a_4'' = H^2$. Each `table` is the 8×8 array of the plane curvatures $K(a, b) = R^{ab}{}_{ab}$ (zero on the diagonal); it is kept in `planes` for the check and drawn with the colour map `RdBu_r` (red positive, blue negative) from -6 to 6.

```
    for a in range(8):
        for b in range(8):
            if a != b:
                ax.text(b, a, f"{table[a, b]:g}", ha="center", va="center",
                        fontsize=8)
    ax.set_xticks(range(8), NAMES)
    ax.set_yticks(range(8), NAMES)
    ax.set_title(f"$a_4' = 2H$, $a_4'' = {a2:g}\\,H^2$")
    ax.grid(False)
fig.colorbar(picture, ax=list(axes), shrink=0.8, label="$K(a, b)$ in units of $H^2$")
```

The values off the diagonal are written into the squares (the format `:g` writes a number without needless zeros), the rows and columns get the coordinate names, each panel its title, and one colour bar serves both panels.

```
save_figure(fig, "curvature_of_planes",
            "The curvature $K(a, b) = R^{ab}_{\\ ab}$ of the plane of the coordinate "
            ...)
check(planes[0.0][1, 2] == 3.0 and planes[0.0][1, 5] == -5.0
      and planes[0.0][1, 0] == -1.0 and planes[1.0][1, 4] == 5.0
      and planes[1.0][5, 4] == 3.0 and planes[0.0][4, 0] == 0.0,
      "plane curvatures at a4' = 2H: 3, -5, -1; with x4: 4 + a4'' and 4 - a4''; "
      "x4 with x0: 0")
```

After saving, the check reads six entries: $K(x_1, x_2) = 4 - 1 = 3$, $K(x_1, x_5) = -(4 + 1) = -5$, $K(x_1, x_0) = -1$, $K(x_1, x_4) = 4 + 1 = 5$ and $K(x_5, x_4) = 4 - 1 = 3$ at $a_4'' = H^2$, and $K(x_4, x_0) = 0$ (in units of H^2), the table of Section 11.10. Fifteenth PASS line.

What Figure 11b.2 shows. Two 8×8 tables of the plane curvatures in units of H^2. Red blocks of 3 inside 3-space and inside the extra times, blue blocks of -5 between them, light blue -1 for every plane with x_0, and 0 for the plane of x_4 and x_0. The row and column of x_4 hold 4 on the left; on the

right, with $a_4'' = H^2$, they hold 5 towards 3-space and 3 towards the extra times: the acceleration of a_4 enters 3-space and the extra times with opposite signs.

In [10], the whole Riemann tensor (Figure 11b.3).

```
point = {"h": 1.0, "a1": 2.0, "a2": 1.0, "cot": 1.0 / np.sqrt(3.0)}
whole = np.zeros((64, 64))
for (a, b, c, d), value in RIEMANN.items():
    whole[8 * a + b, 8 * c + d] = value_at(value, **point)
```

The point $H = 1$, $a_4' = 2$, $a_4'' = 1$, $z = \pi/3$, where $\cot z = 1/\sqrt{3}$. `np.zeros((64, 64))` is a 64×64 array of zeros; every nonzero component is put into row $8a + b$ (the upper pair) and column $8c + d$ (the lower pair). `**point` passes the four entries of the dictionary as the named arguments of `value_at`.

```
fig, ax = plt.subplots(figsize=(6.8, 6.2))
largest = np.abs(whole).max()
picture = ax.imshow(whole, cmap="RdBu_r", vmin=-largest, vmax=largest)
for edge in range(8, 64, 8):  # lines between the blocks
    ax.axhline(edge - 0.5, color="0.8", lw=0.5)
    ax.axvline(edge - 0.5, color="0.8", lw=0.5)
```

The colour scale runs from minus to plus the largest size, so that 0 is white. Thin grey lines separate the blocks of eight rows and columns that share their first label.

```
ticks = list(range(3, 64, 8))  # the middle of each block
ax.set_xticks(ticks, [f"c = {name}" for name in NAMES], rotation=90, fontsize=8)
ax.set_yticks(ticks, [f"a = {name}" for name in NAMES], fontsize=8)
ax.set_xlabel("lower pair $(x_c, x_d)$, column $8c + d$")
ax.set_ylabel("upper pair $(x_a, x_b)$, row $8a + b$")
ax.set_title("All components $R^{ab}{}_{cd}$ at one point")
ax.grid(False)
fig.colorbar(picture, ax=ax, shrink=0.8, label="value (units of $H^2$)")
save_figure(fig, "riemann_matrix",
            "All 4096 components of the Riemann tensor $R^{ab}_{\\ \\ cd}$ of the "
            ...)
check(int(np.count_nonzero(whole)) == 156,
      "156 of the 4096 components are not zero at this point")
```

Marks at the middle of each block, axis titles, title, colour bar and the saved figure; the check counts the nonzero entries of the array: 156 (`np.count_nonzero`). Sixteenth PASS line.

What Figure 11b.3 shows. A 64×64 table, mostly white. Along the main diagonal ($a = c$, $b = d$) lie the plane curvatures; along the second diagonal pattern ($a = d$, $b = c$) their sign-reversed copies. The scattered squares away from these lines are the 48 components that mix x_4 and x_0, such as ${R^{x_1 x_4}}_{x_1 x_0} = H a_4' \cot z$.

In [11], the mixed terms cancel (Figure 11b.4).

```
mixing = [sp.expand(RIEMANN.get((4, c, 0, c), 0)) for c in range(1, 8)]  # x1..x7
for c, term in enumerate(mixing, 1):
```

```
    say(f"R^(x4 {NAMES[c]})_(x0 {NAMES[c]}) = {term}")
total = sp.expand(sum(mixing))
say(f"sum over c = {total} (b4 = 1)")
total_b4 = sp.simplify(sum(RIEMANN_B4.get((4, c, 0, c), 0) for c in range(1, 8)))
say(f"with a general b4: sum over c = {total_b4}")
```

The seven terms $R^{x_4 c}{}_{x_0 c}$ of the Ricci component $R^{x_4}{}_{x_0}$, for $c = x_1$ to x_7 (numbers 4 and 0 are x_4 and x_0; `enumerate(mixing, 1)` counts the terms from 1, so that `NAMES[c]` names the direction). The output: `A1*C*H` three times, 0 for $c = x_4$, `-A1*C*H` three times, and the sum 0 at $b_4 = 1$, as derived in Section 11.10. `total_b4` is the same sum with a general b_4 (from `RIEMANN_B4`): `3*B1*C*H /(2*B0)`, that is $\frac{3}{2} H \cot z \, b_4'/b_4$; the second check compares it with this formula and with the record's mixed component of the Einstein tensor.

```
fig, ax = plt.subplots(figsize=(7.0, 4.0))
heights = [value_at(term, h=1.0, a1=1.0, cot=1.0) for term in mixing]
colours = ["tab:red"] * 3 + ["0.6"] + ["tab:blue"] * 3
ax.bar(NAMES[1:], heights, color=colours)
ax.text(3, 0.05, "0", ha="center", va="bottom")  # the term of c = x4 is zero
ax.axhline(0.0, color="black", lw=0.8)
```

The seven terms at $H = 1$, $a_4' = 1$, $\cot z = 1$ as bars, red for 3-space, grey for x_4, blue for the extra times; `NAMES[:7]` are the first seven names. A small "0" marks the bar of height zero, and a black line marks the value 0.

```
ax.set_xlabel("the direction $c$ of the term $R^{x_4 c}{}_{x_0 c}$")
ax.set_ylabel("value (units of $H^2$)")
ax.set_title(f"Seven terms of $R^{{x_4}}{{}}_{{x_0}}$; their sum is {total}")
save_figure(fig, "mixing_terms_cancel",
            "The seven terms $R^{x_4 c}_{\\ \\ x_0 c}$, $c = x_1$ to $x_7$, whose sum "
            "is the Ricci component $R^{x_4}_{\\ x_0}$, at $H = 1$, "
            ...)
check(total == 0 and sp.expand(mixing[0] - H * A1 * C) == 0,
      "the seven terms of R^x4_x0 are +H a4' cot z (three times), -H a4' cot z (three "
      "times) and 0, and cancel exactly at b4 = 1")
check(sp.simplify(total_b4 - sp.Rational(3, 2) * H * C * B1 / B0) == 0
      and sp.simplify(total_b4 - from_mathematica(
          curvature["einsteinMixed"]["x4,x0"]["mathematica"])) == 0,
      "with b4: R^x4_x0 = (3/2) H cot z b4'/b4, the record's G^x4_x0",
      record=f"{RESULTS}/curvature.json, einsteinMixed x4,x0")
```

In an f-string a doubled brace `{{` prints one brace, so the title reads $R^{x_4}{}_{x_0}$ followed by the sum. The check requires the sum to be exactly 0 and the first term to be $H a_4' \cot z$. PASS lines seventeen and eighteen.

What Figure 11b.4 shows. Three red bars of height $+1$ (x_1, x_2, x_3), a grey bar of height 0 (x_4) and three blue bars of height -1 (x_5, x_6, x_7), in units of H^2: the three inflating and the three deflating directions cancel exactly.

In [12], exact polynomial arithmetic and GKD.

```
from fractions import Fraction  # exact fractions of whole numbers

ONE = {(0, 0, 0, 0): Fraction(1)}  # the polynomial 1
```

From here on the notebook computes with its own exact polynomials, independent of sympy's: a polynomial in H, A_1, A_2, C is a dictionary from the exponents $(e_H, e_{A_1}, e_{A_2}, e_C)$ of each monomial to its coefficient, a `Fraction` (an exact fraction of whole numbers); e_C may be negative. `ONE` is the polynomial 1.

```
def poly_mul(p, q):
    out = {}
    for m1, c1 in p.items():
        for m2, c2 in q.items():
            m = (m1[0] + m2[0], m1[1] + m2[1], m1[2] + m2[2], m1[3] + m2[3])
            out[m] = out.get(m, 0) + c1 * c2
    return {m: c for m, c in out.items() if c != 0}
```

The product of two polynomials (docstring left out): every monomial of the first times every monomial of the second, which adds the exponents and multiplies the coefficients; equal monomials are collected, and monomials whose coefficient became 0 are dropped.

```
def poly_add(p, q, factor=1):
    out = dict(p)
    for m, c in q.items():
        out[m] = out.get(m, 0) + factor * c
    return {m: c for m, c in out.items() if c != 0}
```

`poly_add(p, q, factor)` is $p + \text{factor} \cdot q$: a copy of `p` (`dict(p)`), to which each monomial of `q` times the factor is added; zeros are dropped.

```
def to_poly(expr):
    poly = sp.Poly(sp.expand(expr * C ** 8), H, A1, A2, C)
    return {(m[0], m[1], m[2], m[3] - 8): Fraction(int(v.p), int(v.q))
            for m, v in zip(poly.monoms(), poly.coeffs())}
```

`to_poly` turns a sympy expression into this form. `sp.Poly` needs non-negative powers, so the expression is first multiplied by C^8 (no component has a power of C below -8); `poly.monoms()` lists the exponents and `poly.coeffs()` the coefficients of the monomials; 8 is subtracted from the exponent of C again, and each sympy fraction `v` becomes a `Fraction` of its numerator `v.p` and denominator `v.q`.

```
def gkd(lower, upper):
    position = {}
    for place, label in enumerate(upper):
        if label in position:
            return 0
        position[label] = place
    sigma = [position.get(label) for label in lower]
```

```
    if None in sigma or len(set(sigma)) < len(sigma):
        return 0
    inversions = sum(1 for i in range(len(sigma)) for j in range(i + 1, len(sigma))
                     if sigma[i] > sigma[j])
    return 1 if inversions % 2 == 0 else -1
```

The rule GKD of Notebook 11a (In [4]), written more compactly: `position.get(label)` gives `None` for a lower label that is missing above, and the test `None in sigma` then returns 0 (case c); a repeated place returns 0 (case a); otherwise the sign of the inversions.

```
ENTRIES = [(key, to_poly(RIEMANN[key])) for key in sorted(RIEMANN)]  # 156 entries
LOWER_MASK = np.array([(1 << a) | (1 << b) for (a, b, c, d), _ in ENTRIES])
UPPER_MASK = np.array([(1 << c) | (1 << d) for (a, b, c, d), _ in ENTRIES])
```

The 156 nonzero entries, sorted by their labels, each with its polynomial. For each entry $R^{ab}{}_{cd}$ the bit masks of Section 11.12 are stored: its upper labels a, b go into the delta's LOWER list and its lower labels c, d into the delta's UPPER list. The operator written with two less-than signs shifts the number 1 to the left by the given number of places, so it is 2^a; the vertical bar is the bitwise OR, so the mask of $\{a, b\}$ is $2^a + 2^b$. `np.array` holds the 156 masks, so that one comparison can test all of them at once.

```
report("nonzero curvature entries in the sums", len(ENTRIES))
check(gkd([0, 1, 2], [1, 2, 0]) == 1 and gkd([0, 1], [1, 0]) == -1,
      "gkd: a cycle of three labels is even (+1), an exchange of two odd (-1)",
      record=f"{RESULTS}/lovelock-report.json, gkdSelfCheck")
```

RESULT: 156 entries. The check repeats the two values that the Rust program records for itself in the field `gkdSelfCheck` of its report: $+1$ for the cycle $(0, 1, 2) \to (1, 2, 0)$ and -1 for one exchange. Nineteenth PASS line.

In [13], the Lovelock sum. This cell only defines a function; it prints nothing.

```
def lovelock_sum(k, free_pair):
    pairs = [(h, j) for h in range(8) for j in range(8)] if free_pair else [None]
    weights, leaves, calls = {}, 0, 0
```

`lovelock_sum(k, free_pair)` computes $P_{(k)}$ for all 64 pairs (h, j) when `free_pair` is true, and $L_{(k)}$ (one sum, marked `None`) otherwise. `weights` collects, per pair, the summed GKD weight of each set of entries; `leaves` and `calls` count.

```
    for pair in pairs:
        start_lower = 1 << pair[1] if pair else 0  # j is the first lower label
        start_upper = 1 << pair[0] if pair else 0  # h is the first upper label
        stack = [((), start_lower, start_upper)]
```

For a tensor component the delta's lower list starts with j and its upper list with h, so the masks start with these labels; for the scalar they start empty. The **stack** is a list of partial combinations still to be extended, each a tuple of the chosen entry numbers with the two masks; it starts with the empty combination.

```
        while stack:
            chosen, lower_mask, upper_mask = stack.pop()
            if len(chosen) == k:  # a leaf
                leaves += 1
                if lower_mask != upper_mask:
                    continue  # a lower label is missing above: GKD = 0
```

`while stack:` repeats as long as the stack is not empty; `stack.pop()` takes the last partial combination off it. A combination of k entries is a leaf and is counted. If its two masks differ, some lower label is missing above, GKD would be 0 (case c), and the leaf is dropped (step 3 of Section 11.12).

```
                lower = ([pair[1]] if pair else []) + [
                    x for i in chosen for x in ENTRIES[i][0][:2]]  # j, j1, ..., j2k
                upper = ([pair[0]] if pair else []) + [
                    x for i in chosen for x in ENTRIES[i][0][2:]]  # h, h1, ..., h2k
                sign = gkd(lower, upper)
                calls += 1
```

The two lists of the delta: j followed by the upper labels of the chosen entries in order (`ENTRIES[i][0][:2]` is the pair a, b of entry `i`), and h followed by their lower labels (`[2:]` is c, d). GKD is called, and the call is counted.

```
                if sign != 0:
                    bucket = weights.setdefault(pair, {})
                    key = tuple(sorted(chosen))  # the set of entries
                    bucket[key] = bucket.get(key, 0) + sign
                continue
```

A nonzero value is added to the weight of the SET of chosen entries (`sorted` makes the key independent of the order), because the product of the entries does not depend on their order. `continue` goes back to the top of the `while` loop.

```
            free = np.nonzero(((LOWER_MASK & lower_mask) == 0)
                              & ((UPPER_MASK & upper_mask) == 0))[0]
            for i in free:  # every entry that repeats no label
                stack.append((chosen + (int(i),), lower_mask | int(LOWER_MASK[i]),
                              upper_mask | int(UPPER_MASK[i])))
```

A combination with fewer than k entries is extended (step 2 of Section 11.12). `LOWER_MASK & lower_mask` is computed for all 156 entries at once; `== 0` marks the entries that share no label with the lower list so far, and the same for the upper list; `&` between the two true/false arrays keeps the entries that pass both tests, and `np.nonzero(...)[0]` lists their numbers. Each such entry is appended to the combination, and the masks grow by its labels (bitwise OR).

```
    products = {}  # set of entries -> the product of their polynomials
    result = {}
    for pair, bucket in weights.items():
```

```
        total = {}
        for key, weight in bucket.items():
            if weight == 0:
                continue
            if key not in products:
                product = ONE
                for i in key:
                    product = poly_mul(product, ENTRIES[i][1])
                products[key] = product
            total = poly_add(total, products[key], weight)
        if total:
            result[pair] = total
    return result, leaves, calls
```

After the search, every set of entries with a nonzero total weight is multiplied out once (and remembered in `products`, because the same set appears for many pairs), multiplied by its weight and added to the component (step 4). Components that are not zero are returned in `result`, together with the two counters.

In [14], the sums of orders 1 to 3.

```
P, L, MY_COUNTERS = {}, {}, {}
for k in (1, 2, 3):
    P[k], leaves, calls = lovelock_sum(k, free_pair=True)
    scalar, scalar_leaves, scalar_calls = lovelock_sum(k, free_pair=False)
    L[k] = scalar.get(None, {})
    MY_COUNTERS[k] = (leaves, calls, scalar_calls)
    say(f"k = {k}: leaves {leaves:7d}, GKD calls {calls:6d}, scalar GKD calls "
        f"{scalar_calls:6d}, nonzero components {len(P[k])}")
```

For each order the tensor and the scalar are computed (about ten seconds, mostly for $k = 3$), and the counters are stored and printed: 5616, 176640, 1128960 leaves; 696, 32640, 495360 GKD calls; 108, 7200, 213120 scalar calls; and 8 nonzero components for every order.

```
same_counters = all(
    MY_COUNTERS[k] == (COUNTERS[k]["leaves"], COUNTERS[k]["gkdCalls"],
                       COUNTERS[k]["scalarGkdCalls"])
    and COUNTERS[k]["gkdNonzero"] == COUNTERS[k]["gkdCalls"]
    and len(P[k]) == 8 and COUNTERS[k]["nonzeroComponents"] == 10
    for k in (1, 2, 3))
check(same_counters, "the Python sums reproduce the counters of the Rust sums; "
      "nonzero components: 8 at b4 = 1, 10 (with x4-x0, x0-x4) for a general b4",
      record=f"{RESULTS}/lovelock-report.json, counters k = 1, 2, 3")
```

The Python search, written independently, finds exactly the counters of the Rust search, and every GKD call of the record is nonzero. The numbers of nonzero components differ in the expected way: 8 on the background $b_4 = 1$ in Python, 10 in the record of the Rust program, which keeps b_4 general and also finds the two mixed components x_4-x_0 and x_0-x_4. Twentieth PASS line.

In [15], every component against the record.

```
tensors = json.loads((OUT_FOLDER / "lovelock-tensors.json").read_text(
    encoding="utf-8"))

def from_monomials(monomials):
    out = {}
    for numerator, denominator, e in monomials:
        if any(e[9:13]):  # a derivative of b4: zero on the background b4 = 1
            continue
        if e[3] or e[4] or e[5] or e[6]:  # 3rd, 4th derivative, e^a4 or sin^(1/3)
            raise ValueError("unexpected symbol in a Lovelock component")
        key = (e[0], e[1], e[2], e[7])  # e[8], the power of b4^(1/2), drops out
        out[key] = out.get(key, 0) + Fraction(numerator, denominator)
    return {key: value for key, value in out.items() if value != 0}
```

The program's file lists every component as exact monomials, each a numerator, a denominator and thirteen exponents (of H, a_4', a_4'', a_4''', a_4'''', e^{a_4}, $\sin^{1/3} z$, $\cot z$, $Q = b_4^{1/2}$, b_4', b_4'', b_4''', b_4''''). `from_monomials` rebuilds a component on the background $b_4 = 1$ as a polynomial dictionary: a monomial with a derivative of b_4 (`any(e[9:13])`) is left out, and the power of Q drops out because $Q = 1$, so that monomials which then agree are added (`out.get(key, 0) + ...`); if any of the exponents 3 to 6 were not 0 it would stop, so the components contain only H, a_4', a_4'' and $\cot z$.

```
agree = {}
for k in (1, 2, 3):
    block = tensors[f"P{k}_mixed_up_h_down_j"]
    agree[k] = all(from_monomials(block[f"{NAMES[h]},{NAMES[j]}"]["monomials"])
                   == P[k].get((h, j), {}) for h in range(8) for j in range(8))
    nonzero = " ".join(sorted(f"{NAMES[h]},{NAMES[j]}" for h, j in P[k]))
    say(f"k = {k}: nonzero components (h, j): {nonzero}")
```

For each order the record's 64 components, stored under keys such as `"x1,x1"`, are compared exactly with the Python components (a missing Python component is the empty polynomial, zero). The nonzero components are printed: for every order only the eight diagonal ones, x_0x_0 to x_7x_7.

```
check(all(agree.values()),
      "all 3 x 64 components of P(1), P(2), P(3) equal the Rust components exactly",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, checks "
             "rust_k1_mixed_components_agree, rust_k2_mixed_components_agree and "
             "rust_k3_mixed_components_agree")
scalars_agree = all(to_poly(from_mathematica(tensors[f"L{k}"]).subs(BACKGROUND))
                    == L[k] for k in (1, 2, 3))
check(scalars_agree, "the scalars L(1), L(2), L(3) equal the Rust scalars exactly "
      "(at b4 = 1)",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, checks "
             "rust_L1_agrees, rust_L2_agrees and rust_L3_agrees")
check(all(set(P[k]) == {(h, h) for h in range(8)} for k in (1, 2, 3)),
      "only the 8 diagonal components are nonzero, for k = 1, 2, 3")
```

Three checks: all 3×64 components agree exactly; the three scalars of the record (in Mathematica text, read with `from_mathematica`) equal the Python scalars; and the nonzero components are

exactly the eight diagonal ones (a set comprehension in braces). PASS lines twenty-one to twenty-three. In particular no Lovelock tensor has an x_4-x_0 component at $b_4 = 1$ (the record's mixed components contain b'_4 and vanish there).

In [16], the literal sums of orders 1 and 2.

```
import itertools  # all ordered lists of k entries

def literal_sum(k):
    pairs = [None] + [(h, j) for h in range(8) for j in range(8)]
    weights, calls = {}, 0
    for chosen in itertools.product(range(len(ENTRIES)), repeat=k):
        lower = [x for i in chosen for x in ENTRIES[i][0][:2]]  # j1, ..., j2k
        upper = [x for i in chosen for x in ENTRIES[i][0][2:]]  # h1, ..., h2k
        key = tuple(sorted(chosen))  # the set of entries of this product
```

`literal_sum` does NOT skip anything: `itertools.product(range(156), repeat=k)` runs through all 156^k ordered lists of k entries, and for each the two lists of the delta are built.

```
        for pair in pairs:
            if pair is None:  # the scalar: no free pair
                sign = gkd(lower, upper)
            else:  # the tensor: j first in the lower list, h first in the upper
                sign = gkd([pair[1]] + lower, [pair[0]] + upper)
            calls += 1
            if sign != 0:
                bucket = weights.setdefault(pair, {})
                bucket[key] = bucket.get(key, 0) + sign
```

For the scalar and for each of the 64 pairs, GKD is called on the complete lists, with no test before the call: $65 \cdot 156^k$ calls. Nonzero values are added to the weights as before.

```
    result = {}
    for pair, bucket in weights.items():
        total = {}
        for key, weight in bucket.items():
            product = ONE
            for i in key:
                product = poly_mul(product, ENTRIES[i][1])
            total = poly_add(total, product, weight)
        if total:
            result[pair] = total
    return result, calls
```

The weighted products are multiplied out and added, as in In [13], and the components are returned with the number of calls.

```
record_checks = {c["name"]: c for c in json.loads(repository_file(
    "Revision/gkd_lovelock/results/python-lovelock-report.json").read_text(
        encoding="utf-8"))["checks"]}
```

The checks of the Revision's sympy report are read into a dictionary by name.

```
for k in (1, 2):
    literal, calls = literal_sum(k)
    recorded = record_checks[f"k{k}_unpruned_literal_sum_agrees"]
    recorded_calls = int(re.search(r"(\d+) kdelta calls", recorded["detail"]).group(1))
    say(f"k = {k}: {calls} GKD calls (the record: {recorded_calls})")
```

For $k = 1$ and 2 the literal sum is computed (about 15 seconds in all), and the number of calls stated in the record's check text (the digits before "kdelta calls") is read. Output: 10140 and 1581840 calls, both equal to the record.

```
    same = (literal.pop(None, {}) == L[k]
            and all(literal.get(hj, {}) == P[k].get(hj, {})
                    for hj in set(literal) | set(P[k])))
    check(same and calls == recorded_calls == 65 * 156 ** k
          and recorded["verdict"] == "PASS",
          f"the literal sum of order {k}, without skipping, gives the same P({k}) "
          f"and L({k})",
          record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
                 f"k{k}_unpruned_literal_sum_agrees")
```

`literal.pop(None, {})` takes the scalar out of the result; it must equal $L_{(k)}$, and every component, over the union (`|`) of the components of both results, must equal $P_{(k)}$. The check also requires the number of calls to be $65 \cdot 156^k$ and the record's verdict PASS. PASS lines twenty-four and twenty-five: the skipping changes nothing.

In [17], order 4 has no term.

```
seven_labels = True
for h in range(8):
    for j in range(8):
        stack = [((), 1 << j, 1 << h)]
        while stack:
            chosen, lower_mask, upper_mask = stack.pop()
            if len(chosen) == 3:  # a leaf of order 3
                seven_labels = seven_labels and bin(lower_mask).count("1") == 7
                continue
```

The search of In [13] is repeated for order 3 without calling GKD. At every leaf `bin(mask)` writes the mask in binary and `.count("1")` counts its ones, the number of labels in the lower list; it must be 7 (j and the six upper labels of three entries).

```
            free = np.nonzero(((LOWER_MASK & lower_mask) == 0)
                              & ((UPPER_MASK & upper_mask) == 0))[0]
            for i in free:
                stack.append((chosen + (int(i),), lower_mask | int(LOWER_MASK[i]),
                              upper_mask | int(UPPER_MASK[i])))
check(seven_labels and COUNTERS[4]["leaves"] == 0,
      "every leaf of order 3 uses 7 labels, so P(4) has no term: P(4) = 0",
      record=f"{RESULTS}/lovelock-report.json, check k4_tensor_vanishes")
```

The extension step as before. Since every leaf of order 3 already uses seven different lower labels, a fourth entry would need nine different labels out of eight; together with the record's counter of 0 leaves for $k = 4$ the check confirms $P_{(4)} = 0$. Twenty-sixth PASS line.

In [18], order 1 is Einstein's tensor.

```
RM = dict(ENTRIES)  # (a, b, c, d) -> R^ab_cd as a polynomial dict

def poly_sum(polynomials):
    total = {}
    for p in polynomials:
        total = poly_add(total, p)
    return total
```

`RM` is the dictionary of the 156 entries; `poly_sum` adds a list of polynomials (docstring left out).

```
RIC = {(h, j): poly_sum(RM.get((h, a, j, a), {}) for a in range(8))
       for h in range(8) for j in range(8)}  # R^h_j
R_SCALAR = poly_sum(RIC[h, h] for h in range(8))  # R
delta = {(h, j): (ONE if h == j else {}) for h in range(8) for j in range(8)}
EINSTEIN = {hj: poly_add(RIC[hj], poly_mul(delta[hj], R_SCALAR), Fraction(-1, 2))
            for hj in RIC}  # G = Ric - R/2
```

The Ricci tensor $R^h{}_j = \sum_a R^{ha}{}_{ja}$ for all 64 pairs, the Ricci scalar, the Kronecker delta as polynomials (1 or empty), and the Einstein tensor $G = \mathrm{Ric} - \frac{1}{2}\delta R$, all with the exact arithmetic of In [12].

```
check(all(P[1].get(hj, {}) == poly_mul({(0, 0, 0, 0): Fraction(-4)}, EINSTEIN[hj])
          for hj in EINSTEIN) and L[1] == poly_add({}, R_SCALAR, 2),
      "P(1) = -4 G for all 64 components and L(1) = 2 R",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, checks "
             "k1_equals_minus_4_einstein and L1_equals_2R")
```

The check of Section 11.14: every component of $P_{(1)}$ equals -4 times the Einstein component (the constant polynomial -4 times G), and $L_{(1)} = 2R$. Twenty-seventh PASS line.

In [19], order 2 is the Gauss-Bonnet tensor.

```
ric_square = poly_sum(poly_mul(RIC[a, b], RIC[b, a]) for a in range(8)
                      for b in range(8))  # R^a_b R^b_a
riem_square = poly_sum(poly_mul(v, RM[(c, d, a, b)]) for (a, b, c, d), v in
                       RM.items() if (c, d, a, b) in RM)  # R^ab_cd R^cd_ab
GB = poly_add(poly_add(poly_mul(R_SCALAR, R_SCALAR), ric_square, -4), riem_square)
```

The two squares $\sum R^a{}_b R^b{}_a$ and $\sum R^{ab}{}_{cd} R^{cd}{}_{ab}$ (only entries whose partner with the pairs exchanged is nonzero contribute), and the Gauss-Bonnet scalar $\mathrm{GB} = R^2 - 4R^a{}_b R^b{}_a + R^{ab}{}_{cd} R^{cd}{}_{ab}$ of Section 11.15.

```
two_h = {}  # 2 H^h_j
for h in range(8):
    for j in range(8):
        t = poly_mul(R_SCALAR, RIC[h, j])
        t = poly_add(t, poly_sum(poly_mul(RIC[h, a], RIC[a, j]) for a in range(8)),
                     -2)
        t = poly_add(t, poly_sum(poly_mul(RM.get((h, a, j, b), {}), RIC[b, a])
                                 for a in range(8) for b in range(8)), -2)
        t = poly_add(t, poly_sum(poly_mul(v, RM.get((b, c, j, a), {}))
                                 for (hh, a, b, c), v in RM.items() if hh == h))
        two_h[h, j] = poly_add(poly_mul({(0, 0, 0, 0): Fraction(4)}, t),
                               poly_mul(delta[h, j], GB), -1)
```

For each pair (h, j) the four sums of Lanczos's tensor (Section 11.15) are collected in `t`: $R\,R^h{}_j$, then $-2\sum_a R^h{}_a R^a{}_j$, then $-2\sum_{a,b} R^{ha}{}_{jb} R^b{}_a$, then $\sum R^{ha}{}_{bc} R^{bc}{}_{ja}$ over the entries with first label h (the name `hh` is the entry's first label). Finally $2\mathcal{H}^h{}_j = 4t - \delta^h_j\,\mathrm{GB}$.

```
check(all(P[2].get(hj, {}) == poly_mul({(0, 0, 0, 0): Fraction(-4)}, two_h[hj])
          for hj in two_h) and L[2] == poly_add({}, GB, 4),
      "P(2) = -8 times the Gauss-Bonnet tensor for all 64 components and L(2) = 4 GB",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, checks "
             "k2_equals_minus_8_gauss_bonnet and L2_equals_4_gauss_bonnet")
```

$-4 \cdot 2\mathcal{H} = -8\mathcal{H}$ must equal $P_{(2)}$ in all 64 components, and $L_{(2)} = 4\,\mathrm{GB}$: the result derived by hand in Section 11.15. Twenty-eighth PASS line.

In [20], the cubic density.

```
T = [{} for _ in range(8)]  # T1 ... T8
for (a, b, c, d), v in RM.items():
    for (c2, d2, e, f), w in RM.items():
        if (c2, d2) == (c, d) and (e, f, a, b) in RM:  # R^ab_cd R^cd_ef R^ef_ab
            T[0] = poly_add(T[0], poly_mul(poly_mul(v, w), RM[(e, f, a, b)]))
```

Eight empty polynomials for the eight invariants (`T[0]` is T_1). For every entry $v = R^{ab}{}_{cd}$ and every entry w whose upper pair is (c, d), the product with $R^{ef}{}_{ab}$ is added to T_1, when that entry is nonzero.

```
    for e in range(8):
        for f in range(8):
            if (c, e, b, f) in RM and (d, f, a, e) in RM:  # R^ab_cd R^ce_bf R^df_ae
                T[1] = poly_add(T[1], poly_mul(poly_mul(v, RM[(c, e, b, f)]),
                                               RM[(d, f, a, e)]))
        if (c, d, b, e) in RM:  # R^ab_cd R^cd_be R^e_a
            T[2] = poly_add(T[2], poly_mul(poly_mul(v, RM[(c, d, b, e)]), RIC[e, a]))
    T[4] = poly_add(T[4], poly_mul(poly_mul(v, RIC[c, a]), RIC[d, b]))  # R R^c_a R^d_b
```

Still inside the loop over $v = R^{ab}{}_{cd}$: $T_2 = R^{ab}{}_{cd} R^{ce}{}_{bf} R^{df}{}_{ae}$ over e, f; $T_3 = R^{ab}{}_{cd} R^{cd}{}_{be} R^e{}_a$ over e; and $T_5 = R^{ab}{}_{cd} R^c{}_a R^d{}_b$ (the comment's first R stands for the entry v).

```
T[3] = poly_mul(R_SCALAR, riem_square)  # R R^ab_cd R^cd_ab
T[5] = poly_sum(poly_mul(poly_mul(RIC[a, b], RIC[b, c]), RIC[c, a])
                for a in range(8) for b in range(8) for c in range(8))
T[6] = poly_mul(R_SCALAR, ric_square)  # R R^a_b R^b_a
T[7] = poly_mul(poly_mul(R_SCALAR, R_SCALAR), R_SCALAR)  # R^3
```

The remaining four invariants: $T_4 = R\,R^{ab}{}_{cd}R^{cd}{}_{ab}$, $T_6 = R^{a}{}_{b}R^{b}{}_{c}R^{c}{}_{a}$, $T_7 = R\,R^{a}{}_{b}R^{b}{}_{a}$, $T_8 = R^3$.

```
density = {}
for coefficient, t in zip([2, 8, 24, 3, 24, 16, -12, 1], T):
    density = poly_add(density, t, coefficient)
check(L[3] == poly_add({}, density, 8),
      "L(3) = 8 (2 T1 + 8 T2 + 24 T3 + 3 T4 + 24 T5 + 16 T6 - 12 T7 + T8)",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "L3_equals_8_cubic_lovelock_density")
```

The cubic density with the record's coefficients, and the check $L_{(3)} = 8\times$ density. Twenty-ninth PASS line.

In [21], the expansion along the column of h.

```
def expansion_sum(k):
    result = {}
    for h in range(8):
        first = [i for i, (key, _) in enumerate(ENTRIES) if key[0] == h]
```

`expansion_sum(k)` computes $Y_{(k)}$ of Section 11.13 (docstring left out). For each h, `first` lists the entries whose first upper label is h: these are the possible first factors $R^{hj_2}{}_{h_1h_2}$.

```
        for j in range(8):
            bucket = {}
            stack = []
            for i in first:  # the first factor R^{h j2}_{h1 h2}
                a, b, c, d = ENTRIES[i][0]
                if b != j:  # j2 = j would repeat j in the lower list: GKD = 0
                    stack.append(((i,), (1 << j) | (1 << b), (1 << c) | (1 << d)))
```

For each j the search starts with every possible first factor whose second upper label j_2 differs from j (otherwise the delta's lower list $(j, j_2, \dots)$ would repeat a label). The lower mask holds j and j_2; the upper mask the two lower labels h_1, h_2 of the factor. The label h itself is not in the delta of $Y_{(k)}$.

```
            while stack:
                chosen, lower_mask, upper_mask = stack.pop()
                if len(chosen) == k:  # a leaf
                    if lower_mask != upper_mask:
                        continue  # a lower label is missing above: GKD = 0
                    lower = [j, ENTRIES[chosen[0]][0][1]] + [
                        x for i in chosen[1:] for x in ENTRIES[i][0][:2]]
                    upper = [x for i in chosen for x in ENTRIES[i][0][2:]]
```

```
                    sign = gkd(lower, upper)
                    if sign != 0:
                        key = tuple(sorted(chosen))
                        bucket[key] = bucket.get(key, 0) + sign
                    continue
```

The same search as in In [13], with the lists of $Y_{(k)}$: the lower list is j, then j_2 (the second upper label of the first factor), then the upper labels of the other factors (`chosen[1:]` leaves out the first); the upper list is the lower labels of all factors.

```
                free = np.nonzero(((LOWER_MASK & lower_mask) == 0)
                                  & ((UPPER_MASK & upper_mask) == 0))[0]
                for i in free:
                    stack.append((chosen + (int(i),), lower_mask | int(LOWER_MASK[i]),
                                  upper_mask | int(UPPER_MASK[i])))
            total = {}
            for key, weight in bucket.items():
                product = ONE
                for i in key:
                    product = poly_mul(product, ENTRIES[i][1])
                total = poly_add(total, product, weight)
            result[h, j] = total
    return result
```

The extension step and the multiplication of the weighted products, as before; the component (h, j) of $Y_{(k)}$ is stored.

```
Y = {k: expansion_sum(k) for k in (1, 2, 3)}
expansion_holds = all(
    P[k].get((h, j), {})
    == poly_add(poly_mul(delta[h, j], L[k]), Y[k][h, j], -2 * k)
    for k in (1, 2, 3) for h in range(8) for j in range(8))
check(expansion_holds and all(Y[1][hj] == poly_add({}, RIC[hj], 2) for hj in RIC),
      "P(k) = delta L(k) - 2k Y(k) for all 64 components, k = 1, 2, 3; Y(1) = 2 Ric")
```

$Y_{(k)}$ for the three orders, and the check of the expansion $P_{(k)} = \delta L_{(k)} - 2kY_{(k)}$ in all 3×64 components, together with $Y_{(1)} = 2\,\mathrm{Ric}$ of Section 11.14. Thirtieth PASS line.

In [22], the trace identity.

```
def show(p):
    return str(sp.expand(sum(v * H ** m[0] * A1 ** m[1] * A2 ** m[2] * C ** m[3]
                             for m, v in p.items())))
```

`show` turns a polynomial dictionary back into sympy text, for printing (docstring left out).

```
for k in (1, 2, 3):
    trace = poly_sum(P[k].get((h, h), {}) for h in range(8))
    report(f"Lovelock scalar L({k})", show(L[k]))
```

```
    check(trace == poly_add({}, L[k], 8 - 2 * k),
          f"the trace of P({k}) is (8 - {2 * k}) L({k})",
          record=f"{RESULTS}/lovelock-report.json, check k{k}_trace_identity")
```

For each order the trace $\sum_h {P_{(k)}}^h{}_h$ is formed, the scalar is printed, and the trace identity of Section 11.14 is checked. The RESULT lines give $L_{(1)} = 12a_4'^2 - 84H^2$, $L_{(2)} = -96a_4'^4 - 2112a_4'^2H^2 + 3360H^4$ and $L_{(3)} = 1152a_4'^6 + 31104a_4'^4H^2 + 100224a_4'^2H^4 - 40320H^6$; no a_4'' and no $\cot z$ appear. PASS lines thirty-one to thirty-three.

In [23], the components at one moment (Figure 11b.5).

```
def poly_value(p, h, a1, a2, cot=1):
    total = Fraction(0)
    for (e_h, e_1, e_2, e_c), coefficient in p.items():
        total += (coefficient * Fraction(h) ** e_h * Fraction(a1) ** e_1
                  * Fraction(a2) ** e_2 * Fraction(cot) ** e_c)
    return total
```

`poly_value` evaluates a polynomial dictionary exactly, with fractions, at given values of H, a_4', a_4'' and $\cot z$ (docstring left out).

```
fig, axes = plt.subplots(1, 3, figsize=(13.5, 4.6))
tables = {}
for ax, k in zip(axes, (1, 2, 3)):
    scale = Fraction(-1, 2 ** (k + 1))  # E_(k) = -P_(k) / 2^(k+1)
    # every component at a4' = 2H, a4'' = H^2 with H = 1, exactly, then as a decimal
    table = np.array([[float(scale * poly_value(P[k].get((h, j), {}), 1, 2, 1))
                       for j in range(8)] for h in range(8)])
    tables[k] = table
    largest = np.abs(table).max()
    ax.imshow(table, cmap="RdBu_r", vmin=-largest, vmax=largest)
```

Three panels, one per order. Each component of $E_{(k)} = -P_{(k)}/2^{k+1}$ is evaluated exactly at $H = 1$, $a_4' = 2$, $a_4'' = 1$ (the moment $a_4' = 2H$, $a_4'' = H^2$; the components contain no $\cot z$), turned into a decimal number, and the 8×8 table is drawn with its own colour scale.

```
    for h in range(8):
        for j in range(8):
            if h != j:
                colour = "0.6"  # grey zeros off the diagonal
            elif abs(table[h, j]) > 0.6 * largest:
                colour = "white"  # white on the darkest squares, to stay readable
            else:
                colour = "black"
            ax.text(j, h, f"{table[h, j]:g}", ha="center", va="center",
                    fontsize=6.5 if h == j else 6, color=colour)
```

Every value is written into its square: grey for the zeros off the diagonal, white on the darkest squares and black elsewhere.

```
    ax.set_xticks(range(8), NAMES)
    ax.set_yticks(range(8), NAMES)
    ax.set_xlabel("lower label $j$")
    ax.set_ylabel("upper label $h$")
    ax.set_title(f"$E_{{({k})}}{{}}^h{{}}_j$ in units of $H^{{{2 * k}}}$")
    ax.grid(False)
fig.tight_layout()
save_figure(fig, "lovelock_component_tables",
            "All 64 components $E_{(k)}{}^h{}_j$ of the normalised Lovelock tensors "
            ...)
```

Marks, axis titles and the panel titles (the doubled braces print single braces, so the title reads ${E_{(k)}}^h{}_j$ in units of H^{2k}), then the saved figure.

```
diagonal_ok = all(
    np.count_nonzero(tables[k] - np.diag(np.diag(tables[k]))) == 0
    and tables[k][1, 1] == tables[k][2, 2] == tables[k][3, 3]
    and tables[k][5, 5] == tables[k][6, 6] == tables[k][7, 7]
    and tables[k][0, 0] == (tables[k][1, 1] + tables[k][5, 5]) / 2
    for k in (1, 2, 3))
```

`np.diag(table)` takes the diagonal of a table, and `np.diag` of that diagonal builds a table with only this diagonal; their difference is the part off the diagonal, which must have no nonzero entry. Further, the three space entries must be equal, the three extra-time entries equal, and the hidden entry their mean.

```
say("diagonals (x0 ... x7): " + "; ".join(
    f"E({k}): " + " ".join(f"{v:g}" for v in np.diag(tables[k])) for k in (1, 2, 3)))
check(diagonal_ok and list(np.diag(tables[1])) == [3, 4, 4, 4, 33, 2, 2, 2],
      "at a4' = 2H, a4'' = H^2: only diagonal entries, space and extra-time entries "
      "equal, hidden entry their mean; G = diag(3, 4, 4, 4, 33, 2, 2, 2) H^2")
```

The three diagonals are printed in the order $x_0, \ldots, x_7$: $E_{(1)}$: 3, 4, 4, 4, 33, 2, 2, 2; $E_{(2)}$: 684, 548, 548, 548, −1476, 820, 820, 820; $E_{(3)}$: −22392, −14544 (three times), 40248, −30240 (three times) (Section 11.20 recomputes every one of these entries by hand). With the Einstein tensor of Section 11.10 and $a_4' = 2H$, $a_4'' = H^2$: ${G^{x_1}}_{x_1} = -12 + 1 + 15 = 4$, ${G^{x_4}}_{x_4} = 12 + 21 = 33$, ${G^{x_5}}_{x_5} = -12 - 1 + 15 = 2$, ${G^{x_0}}_{x_0} = 15 - 12 = 3$, in units of H^2, which the check confirms. Thirty-fourth PASS line.

What Figure 11b.5 shows. Three 8×8 tables in units of H^2, H^4 and H^6, each filled only on its diagonal. In each table the first three diagonal squares are equal (3-space), the squares 5 to 7 are equal (extra times), and the last square (hidden direction) lies exactly halfway between them: $(4 + 2)/2 = 3$, $(548 + 820)/2 = 684$, $(-14544 - 30240)/2 = -22392$. The time square x_4 stands apart: in $E_{(1)}$ it is much larger than the others (33 against 2 to 4, all positive); in $E_{(2)}$ and $E_{(3)}$ it has the opposite sign to all the others (−1476 against positive entries, +40248 against negative ones). Section 11.21 proves these patterns for every history.

In [24], the quoted records once more.

```
def verdicts(path):
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    checks = data["checks"]
    if isinstance(checks, dict):  # name -> {"passed": true or false, ...}
        return {name: "PASS" if entry["passed"] else "FAIL"
                for name, entry in checks.items()}
    return {entry["name"]: entry["verdict"] for entry in checks}  # a list of entries
```

The helper of Notebook 11a, In [16]: for one report, a dictionary from the name of each check to PASS or FAIL, for both forms in which the reports store their checks.

```
QUOTED = {  # report -> the checks that this notebook quotes from it
    "python-lovelock-report.json": [
        "rust_riemann_agrees", "rust_k1_mixed_components_agree",
        "rust_k2_mixed_components_agree", "rust_k3_mixed_components_agree",
        "rust_L1_agrees", "rust_L2_agrees", "rust_L3_agrees",
        "k1_unpruned_literal_sum_agrees", "k2_unpruned_literal_sum_agrees",
        "k1_equals_minus_4_einstein", "L1_equals_2R",
        "k2_equals_minus_8_gauss_bonnet", "L2_equals_4_gauss_bonnet",
        "L3_equals_8_cubic_lovelock_density", "normalisation_P1_derived_minus_4",
        "normalisation_P2_derived_minus_8", "normalisation_L3_cubic_derived"],
    "lovelock-report.json": [
        "riemann_antisymmetry", "mixed_riemann_free_of_sin_third",
        "k1_trace_identity", "k2_trace_identity", "k3_trace_identity",
        "k4_tensor_vanishes", "k1_brute_force_numeric", "k2_brute_force_numeric"],
}
```

The 17 checks that the notebook's text quotes from the sympy report and the 8 that it quotes from the Rust report.

```
for report_name, names in QUOTED.items():
    found = verdicts(f"{RESULTS}/{report_name}")
    missing = [name for name in names if found.get(name) != "PASS"]
    say(f"{report_name}: {len(names)} quoted checks; not there or not PASS: "
        f"{missing if missing else 'none'}")
    check(not missing,
          f"the {len(names)} checks quoted from {report_name} are there and PASS",
          record=f"{RESULTS}/{report_name}, checks " + ", ".join(names))
```

For each report the list `missing` collects every quoted check that is absent or not PASS; it is printed ("none") and must be empty (`not missing` is true for an empty list). PASS lines thirty-five and thirty-six.

```
totals = {}
for report_name in ("python-lovelock-report.json", "wolfram-gkd-report.json"):
    data = json.loads(repository_file(f"{RESULTS}/{report_name}").read_text(
        encoding="utf-8"))
    totals[report_name] = (data["checkCount"], data["failedCheckCount"],
                           data["verdict"])
    say(f"{report_name}: {data['checkCount']} checks, {data['failedCheckCount']} "
        f"failed, verdict {data['verdict']}")
```

The numbers of checks of the two verification reports are read and printed: 49 checks, 0 failed, verdict SUCCESS for the sympy report, and 29, 0, SUCCESS for the Wolfram report.

```
check(totals == {"python-lovelock-report.json": (49, 0, "SUCCESS"),
                 "wolfram-gkd-report.json": (29, 0, "SUCCESS")},
      "the sympy verification has 49 checks and the Wolfram verification 29, none "
      "failed",
      record=f"{RESULTS}/python-lovelock-report.json and wolfram-gkd-report.json, "
             "checkCount and failedCheckCount")
```

The counts quoted in the notebook's text are fixed by this check, so a later change of either report would be noticed. Thirty-seventh PASS line.

In [25], the end.

```
figure_files = [f"11b_{k}_{name}.png" for k, name in enumerate(
    ["work_of_the_sums", "curvature_of_planes", "riemann_matrix",
     "mixing_terms_cancel", "lovelock_component_tables"], 1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_files),
      "all five figure files of the notebook exist")
all_checks_passed()
```

As in Notebook 11a, In [17]: the five figure files must exist (thirty-eighth PASS line), and the last line is ALL 38 CHECKS PASSED (notebook 11b). The 38 checks are: 2 in In [3], 4 in In [4], 1 each in In [5], In [6] and In [7], 5 in In [8], 1 each in In [9] and In [10], 2 in In [11], 1 in In [12], 1 in In [14], 3 in In [15], 2 in In [16], 1 each in In [17] to In [21], 3 in In [22], 1 in In [23], 3 in In [24] and 1 in In [25].

11.20 The components of the three tensors for the author's metric

The result (PROVED by exact computation). The Rust program of the record computes all 3×64 components of $P_{(1)}, P_{(2)}, P_{(3)}$ exactly and writes them into the record `lovelock-tensors.json`. The Revision's sympy and Wolfram verifications recompute every one of them independently and find the same (checks `rust_k1_mixed_components_agree` to `rust_k3_mixed_components_agree` of the sympy report, and `k1_P_equals_rust_all_64_components` to `k3_P_equals_rust_all_64_components` of the Wolfram report), and so does Notebook 11b (In [15]). Only the eight diagonal components are nonzero, for every order, on the background $b_4 = 1$; for the metric with a changing b_4 the record also has the mixed components $P^{x_4}{}_{x_0}$ and $P^{x_0}{}_{x_4}$, which contain b_4' (Section 11.21). With $E_{(k)} = -P_{(k)}/2^{k+1}$ and the abbreviations a_4', a_4'' for the derivatives with respect to the time x_4, the independent components are

$$
\begin{aligned}
{E_{(1)}}^{x_1}{}_{x_1} &= -3a_4'^2 + a_4'' + 15H^2, & {E_{(1)}}^{x_4}{}_{x_4} &= 3a_4'^2 + 21H^2,\\
{E_{(1)}}^{x_5}{}_{x_5} &= -3a_4'^2 - a_4'' + 15H^2, & {E_{(1)}}^{x_0}{}_{x_0} &= -3a_4'^2 + 15H^2,
\end{aligned}
$$

$$
\begin{aligned}
{E_{(2)}}^{x_1}{}_{x_1} &= 12a_4'^4 - 24a_4'^2a_4'' + 168a_4'^2H^2 - 40a_4''H^2 - 180H^4,\\
{E_{(2)}}^{x_4}{}_{x_4} &= -36a_4'^4 - 120a_4'^2H^2 - 420H^4,\\
{E_{(2)}}^{x_5}{}_{x_5} &= 12a_4'^4 + 24a_4'^2a_4'' + 168a_4'^2H^2 + 40a_4''H^2 - 180H^4,\\
{E_{(2)}}^{x_0}{}_{x_0} &= 12a_4'^4 + 168a_4'^2H^2 - 180H^4,
\end{aligned}
$$

$$
\begin{aligned}
{E_{(3)}}^{x_1}{}_{x_1} &= -72a_4'^6 + 360a_4'^4 a_4'' - 648a_4'^4 H^2 + 432a_4'^2 a_4'' H^2 - 1944a_4'^2 H^4 + 360a_4'' H^4 + 360H^6,\\
{E_{(3)}}^{x_4}{}_{x_4} &= 360a_4'^6 + 648a_4'^4 H^2 + 1080a_4'^2 H^4 + 2520H^6,\\
{E_{(3)}}^{x_5}{}_{x_5} &= -72a_4'^6 - 360a_4'^4 a_4'' - 648a_4'^4 H^2 - 432a_4'^2 a_4'' H^2 - 1944a_4'^2 H^4 - 360a_4'' H^4 + 360H^6,\\
{E_{(3)}}^{x_0}{}_{x_0} &= -72a_4'^6 - 648a_4'^4 H^2 - 1944a_4'^2 H^4 + 360H^6,
\end{aligned}
$$

with ${E^{x_2}}_{x_2} = {E^{x_3}}_{x_3} = {E^{x_1}}_{x_1}$ and ${E^{x_6}}_{x_6} = {E^{x_7}}_{x_7} = {E^{x_5}}_{x_5}$ for every order. These are exactly the components that the record of the field equations of a_4 lists (`Revision/field_equations_a4/a4-equations.json`, key `lovelockTensors`, compared in its sympy report `Revision/field_equations_a4/reports/python-a4-report.json`, check `json_lovelock_components`); Notebook 11c reads them from the Rust record and compares them with this list (In [2] and In [3]). The components contain only H, a_4' and a_4'': no x_0 (no $\cot z$ and no $\sin^{1/3} z$), no e^{a_4} and no higher derivative. The order-1 components are those of the Einstein tensor of Section 11.10, as Section 11.14 proved they must be.

Every component checked by hand. Take the moment $a_4' = 2H$, $a_4'' = H^2$ of a history in which the extra times deflate and the deflation speeds up. Then $a_4'^2 = 4H^2$, $a_4'^4 = 16H^4$ and $a_4'^6 = 64H^6$ (products of two, four and six factors $2H$). We insert these values into the twelve formulas above and add the whole numbers; because the components x_2, x_3 equal the component x_1 and the components x_6, x_7 equal the component x_5 (stated just above), it suffices to do the components x_1, x_4, x_5 and x_0 of each order. Order 1:

$$
\begin{aligned}
{E_{(1)}}^{x_1}{}_{x_1} &= -3\cdot 4H^2 + H^2 + 15H^2 = (-12+1+15)H^2 = 4H^2,\\
{E_{(1)}}^{x_4}{}_{x_4} &= 3\cdot 4H^2 + 21H^2 = (12+21)H^2 = 33H^2,\\
{E_{(1)}}^{x_5}{}_{x_5} &= -3\cdot 4H^2 - H^2 + 15H^2 = (-12-1+15)H^2 = 2H^2,\\
{E_{(1)}}^{x_0}{}_{x_0} &= -3\cdot 4H^2 + 15H^2 = (-12+15)H^2 = 3H^2.
\end{aligned}
$$

In each line the first step inserts $a_4'^2 = 4H^2$ and $a_4'' = H^2$, the second multiplies out ($3\cdot 4 = 12$) and takes the common factor H^2 out of the sum, and the last adds the whole numbers. Order 2: the four products that occur become $a_4'^4 = 16H^4$, $a_4'^2 a_4'' = 4H^2\cdot H^2 = 4H^4$, $a_4'^2 H^2 = 4H^4$ and $a_4'' H^2 = H^4$ (powers of H multiply by adding their exponents), and H^4 stays H^4. In ${E_{(2)}}^{x_1}{}_{x_1}$, written out factor by factor:

$$
12\cdot 16H^4 - 24\cdot 4H^2\cdot H^2 + 168\cdot 4H^2\cdot H^2 - 40H^2\cdot H^2 - 180H^4 = (192-96+672-40-180)H^4 = 548H^4.
$$

The other three components of order 2 in the same steps (insert, multiply the coefficient of each term by 16, 4, 4 or 1 according to its product, the term in H^4 keeping its coefficient, add):

$$
\begin{aligned}
{E_{(2)}}^{x_4}{}_{x_4} &= (-36\cdot 16 - 120\cdot 4 - 420)H^4 = (-576-480-420)H^4 = -1476H^4,\\
{E_{(2)}}^{x_5}{}_{x_5} &= (12\cdot 16 + 24\cdot 4 + 168\cdot 4 + 40 - 180)H^4 = (192+96+672+40-180)H^4 = 820H^4,\\
{E_{(2)}}^{x_0}{}_{x_0} &= (12\cdot 16 + 168\cdot 4 - 180)H^4 = (192+672-180)H^4 = 684H^4.
\end{aligned}
$$

Order 3: the six products that occur become $a_4'^6 = 64H^6$, $a_4'^4 a_4'' = 16H^4 \cdot H^2 = 16H^6$, $a_4'^4 H^2 = 16H^6$, $a_4'^2 a_4'' H^2 = 4H^2 \cdot H^2 \cdot H^2 = 4H^6$, $a_4'^2 H^4 = 4H^6$ and $a_4'' H^4 = H^6$, so the coefficient of each term is multiplied by 64, 16, 16, 4, 4 or 1 according to its product, and the term in H^6 keeps its coefficient:

$$\begin{aligned}
{E_{(3)}}^{x_1}{}_{x_1} &= (-72 \cdot 64 + 360 \cdot 16 - 648 \cdot 16 + 432 \cdot 4 - 1944 \cdot 4 + 360 + 360)H^6 \\
&= (-4608 + 5760 - 10368 + 1728 - 7776 + 360 + 360)H^6 = -14544H^6, \\
{E_{(3)}}^{x_4}{}_{x_4} &= (360 \cdot 64 + 648 \cdot 16 + 1080 \cdot 4 + 2520)H^6 \\
&= (23040 + 10368 + 4320 + 2520)H^6 = 40248H^6, \\
{E_{(3)}}^{x_5}{}_{x_5} &= (-72 \cdot 64 - 360 \cdot 16 - 648 \cdot 16 - 432 \cdot 4 - 1944 \cdot 4 - 360 + 360)H^6 \\
&= (-4608 - 5760 - 10368 - 1728 - 7776 - 360 + 360)H^6 = -30240H^6, \\
{E_{(3)}}^{x_0}{}_{x_0} &= (-72 \cdot 64 - 648 \cdot 16 - 1944 \cdot 4 + 360)H^6 \\
&= (-4608 - 10368 - 7776 + 360)H^6 = -22392H^6.
\end{aligned}$$

For each component the first line inserts the products, the second line multiplies out each coefficient, and its last step adds the whole numbers. With ${E^{x_2}}_{x_2} = {E^{x_3}}_{x_3} = {E^{x_1}}_{x_1}$ and ${E^{x_6}}_{x_6} = {E^{x_7}}_{x_7} = {E^{x_5}}_{x_5}$ the diagonals at this moment are, in the order $x_0, \ldots, x_7$,

$$\begin{aligned}
E_{(1)} &= (3, 4, 4, 4, 33, 2, 2, 2)H^2, \\
E_{(2)} &= (684, 548, 548, 548, -1476, 820, 820, 820)H^4, \\
E_{(3)} &= (-22392, -14544, -14544, -14544, 40248, -30240, -30240, -30240)H^6,
\end{aligned}$$

exactly the numbers that Notebook 11b prints (In [23], Figure 11b.5).

11.21 Their structure: equal directions, constraint, evolution factor, mean, sign and weight

The components have a clear structure, which Chapter 12 uses at every step. We prove each part by hand from the curvature table of Section 11.10 and from the rule GKD; Notebook 11c confirms every part with exact algebra (In [2] for part (a), In [4] for parts (b) to (h)).

Three tools. (i) **Relabelling.** If a bijection τ of the eight labels is applied to every label of both lists of a generalized delta, its matrix does not change, because $\delta(\tau l_i, \tau u_j) = \delta(l_i, u_j)$ (τ maps equal labels to equal labels and different labels to different labels); so $\delta^{\tau U}_{\tau L} = \delta^U_L$. And because τ runs through all labels exactly once, a sum over all values of the summed labels is unchanged when every summed label is replaced by its image. (ii) **The label 4 and the acceleration.** Every curvature entry that contains a_4'' is a plane entry of a plane (k, x_4), so it carries the label x_4 in its upper pair and in its lower pair (Section 11.10). (iii) **The labels 4 and 0 in the mixed entries.** Every mixed entry, such as ${R^{x_4 k}}_{x_0 k}$ or ${R^{x_0 k}}_{x_4 k}$, has the label x_4 in one of its pairs and x_0 in the other; a plane entry has the same two labels in both pairs.

(a) Only diagonal components (PROVED). In a term of ${P_{(k)}}^h{}_j$ the delta's lower list is j followed by the upper pairs of the factors, and its upper list is h followed by their lower pairs. A plane entry adds the same two labels to both lists. A mixed entry of the first kind (x_4 up, x_0 down) adds x_4 to the lower list and x_0 to the upper list; one of the second kind does the opposite. For a nonzero term the two lists must hold the same labels (case c). If $h \neq j$, the labels j and h must

therefore be exactly x_4 and x_0 in some order, balanced by one more mixed entry of one kind than of the other. So every off-diagonal component other than ${P^{x_4}}_{x_0}$ and ${P^{x_0}}_{x_4}$ vanishes identically. Now take ${P^{x_4}}_{x_0}$: the label x_0 stands in the lower list (as j) and must appear once in the upper list, and x_4 stands in the upper list (as h) and must appear once in the lower list; so each term contains exactly one mixed entry, ${R^{x_4 k}}_{x_0 k}$ or one of its antisymmetric variants, and every other factor avoids both x_4 and x_0: it is a plane curvature among the six transverse directions, $a_4'^2 - H^2$ or $-(a_4'^2 + H^2)$. Apply the relabelling τ that exchanges $x_1 \leftrightarrow x_5$, $x_2 \leftrightarrow x_6$, $x_3 \leftrightarrow x_7$ and keeps x_4 and x_0. It leaves every factor among the transverse directions unchanged (the planes (i, i') and (j, j') have the same curvature, and the planes (i, j) go to planes (j, i)), it leaves the delta unchanged (tool i), and it changes the sign of the mixed entry, because ${R^{x_4 i}}_{x_0 i} = +H a_4' \cot z$ and ${R^{x_4 j}}_{x_0 j} = -H a_4' \cot z$ (Section 11.10). Summing over all relabelled terms is the same sum, so ${P^{x_4}}_{x_0} = -{P^{x_4}}_{x_0}$, hence ${P^{x_4}}_{x_0} = 0$; the same for ${P^{x_0}}_{x_4}$ with the second kind of mixed entry, ${R^{x_0 i}}_{x_4 i} = -H a_4' \tan z$ against ${R^{x_0 j}}_{x_4 j} = +H a_4' \tan z$. This is the cancellation of three inflating against three deflating directions of Section 11.10, now for every order. It holds on the background $b_4 = 1$, where the extra-time entries are the space entries with the sign of the mixed ones reversed; a changing b_4 changes only the extra-time entries, the cancellation is incomplete, and for the metric with b_4 the components ${P^{x_4}}_{x_0}$ and ${P^{x_0}}_{x_4}$ are not zero: they are proportional to b_4' (record `lovelock-tensors.json`; Notebook 11c, In [2]; for Einstein's tensor ${G^{x_4}}_{x_0} = \frac{3}{2} H \cot z \, b_4'/b_4$, Section 11.10). The record finds the same eight nonzero components for every order (`wolfram-gkd-report.json`, field `measurements`, entries `k1NonzeroComponents` to `k3NonzeroComponents`).

(b) The three space directions are alike, and so are the three extra times (PROVED). The relabelling that exchanges x_1 and x_2 is a change of coordinates that leaves the author's metric unchanged ($g_{11} = g_{22}$), so it maps every curvature entry to the entry with the exchanged labels, of the same value. By tool (i) it maps the sum ${P^{x_1}}_{x_1}$ term by term onto ${P^{x_2}}_{x_2}$: the two are equal. The same holds for x_3, and for the extra times x_5, x_6, x_7.

(c) a_4'' appears at most once in each term (PROVED). By tool (ii) an entry with a_4'' puts the label x_4 into both lists of the delta. Two such entries in one term would repeat x_4 in both lists, and GKD would be 0. So every component has the form (polynomial in H, a_4')+$a_4''\cdot$(polynomial in H, a_4').

(d) The time component contains no a_4'' (PROVED). In ${P^{x_4}}_{x_4}$ the label x_4 already stands in both lists (as h and j), so no factor may carry x_4: no entry with a_4'' (tool ii) and no mixed entry (tool iii). The factors are plane curvatures among the directions $x_0, x_1, x_2, x_3, x_5, x_6, x_7$, that is $a_4'^2 - H^2$, $-(a_4'^2 + H^2)$ and $-H^2$. So ${E^{x_4}}_{x_4}$ is a polynomial in $a_4'^2$ and H^2 alone, as the list of Section 11.20 shows. In the field equations this component is the **constraint**, a condition on a_4', not an equation for its change.

(e) Space against extra times: the evolution factor (PROVED). Apply the relabelling τ of part (a) to ${P^{x_1}}_{x_1}$: it becomes ${P^{x_5}}_{x_5}$, term by term, with every factor replaced by its image. The image of a plane entry is the same entry with a_4'' replaced by $-a_4''$ (the table of Section 11.10: (i, x_4) with $a_4'^2 + a_4''$ goes to (j, x_4) with $a_4'^2 - a_4''$, and every other kind of plane goes to a plane with the same curvature). The image of a mixed entry has the opposite sign; but mixed entries occur in pairs in every nonzero term of a diagonal component other than ${P^{x_4}}_{x_4}$ and ${P^{x_0}}_{x_0}$ (the label x_0 must appear in both lists or in neither, so a mixed entry of one kind needs one of the other kind), and two sign changes cancel. Hence

$$E^{x_5}{}_{x_5}(H, a_4', a_4'') = E^{x_1}{}_{x_1}(H, a_4', -a_4'').$$

With part (c) write $E^{x_1}{}_{x_1} = \mathcal{A}_k + a_4''\mathcal{B}_k$, where $\mathcal{A}_k$ and $\mathcal{B}_k$ are polynomials in H and a_4'. Then $E^{x_5}{}_{x_5} = \mathcal{A}_k - a_4''\mathcal{B}_k$ (the identity just proved), and the difference is

$$E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5} = 2\mathcal{B}_k\, a_4'' = a_4''\, F_k(a_4'), \qquad F_k = 2\mathcal{B}_k.$$

This difference is the only combination in which a_4'' survives; in the field equations it is the **evolution equation**, which decides how a_4 changes (Chapter 12). From the components of Section 11.20,

$$F_1 = 2, \qquad F_2 = -16(3a_4'^2 + 5H^2), \qquad F_3 = 144(5a_4'^4 + 6a_4'^2H^2 + 5H^4)$$

(for example $E_{(2)}{}^{x_1}{}_{x_1} - E_{(2)}{}^{x_5}{}_{x_5} = -48a_4'^2a_4'' - 80a_4''H^2 = -16a_4''(3a_4'^2 + 5H^2)$: the terms without a_4'' cancel). The record lists $F = \alpha_1F_1 + \alpha_2F_2 + \alpha_3F_3$ (`a4-equations.json`, key `generalSource`, entry `evolution_F`; `python-a4-report.json`, check `evolution_factorises`); Notebook 11c, In [4], computes the F_k and compares them with the record.

(f) The hidden component (PROVED). The same relabelling maps $P^{x_0}{}_{x_0}$ to itself (τ keeps x_0), with a_4'' replaced by $-a_4''$; in its terms no factor carries x_0, so there are no mixed entries. So $E^{x_0}{}_{x_0}$ is unchanged when a_4'' changes sign, and by part (c) it is linear in a_4'': it contains no a_4''. Section 11.22 proves more: $E^{x_0}{}_{x_0} = \mathcal{A}_k$, the mean of the space and the extra-time components.

(g) Even in a_4': deflation is a choice of sign (PROVED). Reverse the time: use the coordinate $y_4 = -x_4$ instead of x_4. Since $dx_4^2 = dy_4^2$, the metric in the new coordinates has exactly the author's form, with the function $b(y_4) = a_4(-y_4)$ in place of a_4. Its Lovelock components are therefore given by the same polynomials, with $b'(y_4) = -a_4'(x_4)$ and $b''(y_4) = a_4''(x_4)$ (the chain rule: each derivative brings a factor $dx_4/dy_4 = -1$). On the other hand a diagonal component of a tensor with one upper and one lower label does not change under this reflection: the component x_4x_4 is multiplied by $(-1)(-1) = 1$, and the others are not touched (the tensor rule of Section 3.14; $P_{(k)}$ is a tensor, built from the Riemann tensor and the generalized delta, whose entries are the same in every system of coordinates). So every diagonal component satisfies $E(H, -a_4', a_4'') = E(H, a_4', a_4'')$ at every point and for every history. Any two numbers u, v are the values $a_4'(0) = u$, $a_4''(0) = v$ of the history $a_4 = ux_4 + vx_4^2/2$, so the identity holds for all values: **every component is an even function of** a_4'. The list of Section 11.20 shows it: a_4' appears only in even powers. The meaning: replacing a_4 by $-a_4$ along a linear history, $A \to -A$, turns deflating extra times and inflating 3-space into inflating extra times and deflating 3-space, and the Lovelock tensors do not notice. The gravitational side of the field equations does not prefer deflation; deflation of the extra times is a choice of sign (Chapter 12 draws the consequences). Notebook 11c checks the evenness exactly (In [4]) and draws it (In [6], Figure 11c.1).

(h) Weight $2k$ (PROVED in Section 11.11). Every term of $E_{(k)}$ has the weight $2k$ when H and a_4' count 1 and a_4'' counts 2: $E_{(1)}$ is quadratic, $E_{(2)}$ quartic, $E_{(3)}$ of sixth degree in this sense. Notebook 11c checks it by replacing H, a_4', a_4'' by uH, ua_4', u^2a_4'' and finding the factor u^{2k} (In [4]).

One more factorisation used in Chapter 12. The difference of the time and the hidden component is

$$E^{x_4}{}_{x_4} - E^{x_0}{}_{x_0} = 6(a_4'^2 + H^2)V_k, \qquad V_1 = 1, \quad V_2 = -8(a_4'^2 + 5H^2), \quad V_3 = 72(a_4'^4 + 2a_4'^2H^2 + 5H^4).$$

For $k = 2$, line by line:

$$E_{(2)}{}^{x_4}{}_{x_4} - E_{(2)}{}^{x_0}{}_{x_0} = -36a_4'^4 - 120a_4'^2H^2 - 420H^4 - 12a_4'^4 - 168a_4'^2H^2 + 180H^4$$
$$= -48a_4'^4 - 288a_4'^2H^2 - 240H^4$$

(the two components of Section 11.20; collect equal powers),

$$= -48(a_4'^4 + 6a_4'^2H^2 + 5H^4) = -48(a_4'^2 + H^2)(a_4'^2 + 5H^2) = 6(a_4'^2 + H^2)\cdot(-8)(a_4'^2 + 5H^2)$$

(take out -48; the quadratic $u^2 + 6u + 5 = (u+1)(u+5)$ in $u = a_4'^2/H^2$; $-48 = 6\cdot(-8)$). Notebook 11c checks all three (In [5]); the record uses the factor for the linear history (`python-a4-report.json`, check `linear_member_vacuum_factor`).

11.22 The two conservation identities

Every Lovelock tensor has zero covariant divergence (Lovelock's theorem; for the author's metric PROVED by exact computation: `Revision/gkd_lovelock/results/lovelock-report.json`, checks `k1_divergence_free` to `k3_divergence_free`). For the author's metric this one statement becomes two short identities between the components. Section 3.25 derived them for the Einstein tensor; here we derive them for every order, line by line.

The divergence of a diagonal tensor. For a tensor $P^h{}_j$ with one upper and one lower label, the covariant divergence is

$$\nabla_h P^h{}_j = \sum_h \partial_h P^h{}_j + \sum_{h,m} \Gamma^h{}_{hm} P^m{}_j - \sum_{h,m} \Gamma^m{}_{hj} P^h{}_m$$

(one $+\Gamma$ for the upper label, one $-\Gamma$ for the lower label, then the upper label contracted with the derivative; Section 3.15). If P is diagonal, the first sum keeps $h = j$, the second keeps $m = j$, and the third keeps $m = h$:

$$\nabla_h P^h{}_j = \partial_j P^j{}_j + \sum_h \Gamma^h{}_{hj}(P^j{}_j - P^h{}_h) \qquad \text{(no sum over } j\text{)}$$

(the second and third sums combined, since both now run over h).

The time direction, $j = x_4$. The symbols $\Gamma^h{}_{hx_4}$ are a_4' for the three space directions, $-a_4'$ for the three extra times, and 0 for x_4 and x_0 (Section 3.23). So

$$\nabla_h P^h{}_{x_4} = \partial_4 P^{x_4}{}_{x_4} + 3a_4'(P^{x_4}{}_{x_4} - P^{x_1}{}_{x_1}) - 3a_4'(P^{x_4}{}_{x_4} - P^{x_5}{}_{x_5}) = \partial_4 P^{x_4}{}_{x_4} - 3a_4'(P^{x_1}{}_{x_1} - P^{x_5}{}_{x_5})$$

(the three space components are equal, and so are the three extra-time components, Section 11.21 (b); the terms $3a_4'P^{x_4}{}_{x_4}$ cancel). Setting the divergence to zero and multiplying by $-1/2^{k+1}$:

$$\frac{d}{dx_4} E^{x_4}{}_{x_4} = 3a_4'(E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5}). \qquad \text{(I)}$$

The hidden direction, $j = x_0$. Nothing depends on x_0, so $\partial_0 P^{x_0}{}_{x_0} = 0$. The symbols $\Gamma^h{}_{hx_0}$ are $H\cot z$ for the six transverse directions and 0 for x_4; the term $h = x_0$ has the factor $P^{x_0}{}_{x_0} - P^{x_0}{}_{x_0} = 0$. So

$$\nabla_h P^h{}_{x_0} = 3H\cot z\big(P^{x_0}{}_{x_0} - P^{x_1}{}_{x_1}\big) + 3H\cot z\big(P^{x_0}{}_{x_0} - P^{x_5}{}_{x_5}\big) = 3H\cot z\big(2P^{x_0}{}_{x_0} - P^{x_1}{}_{x_1} - P^{x_5}{}_{x_5}\big).$$

Since $H\cot z > 0$ on the patch $0 < z < \pi/2$, zero divergence gives

$$E^{x_0}{}_{x_0} = \tfrac{1}{2}\big(E^{x_1}{}_{x_1} + E^{x_5}{}_{x_5}\big). \qquad \text{(II)}$$

The transverse directions. For j one of $x_1, x_2, x_3, x_5, x_6, x_7$: nothing depends on x_j, and every $\Gamma^h{}_{hj}$ is zero (Section 3.23), so the divergence vanishes without any condition.

What the identities say about the components (PROVED). With Section 11.21 (e), identity (II) gives $E^{x_0}{}_{x_0} = \frac{1}{2}\big((\mathcal{A}_k + a_4''\mathcal{B}_k) + (\mathcal{A}_k - a_4''\mathcal{B}_k)\big) = \mathcal{A}_k$: the hidden component is the space component without its a_4'' part. For $k = 1$: $\frac{1}{2}\big((-3a_4'^2 + a_4'' + 15H^2) + (-3a_4'^2 - a_4'' + 15H^2)\big) = -3a_4'^2 + 15H^2$. Identity (I) gives, since $E^{x_4}{}_{x_4}$ depends on x_4 only through a_4' (Section 11.21 (d)) and by the chain rule $\frac{d}{dx_4}E^{x_4}{}_{x_4} = \frac{\partial E^{x_4}{}_{x_4}}{\partial a_4'}\,a_4''$,

$$\frac{\partial E^{x_4}{}_{x_4}}{\partial a_4'}\,a_4'' = 3a_4'\,a_4''\,F_k \qquad \Longrightarrow \qquad \frac{\partial E^{x_4}{}_{x_4}}{\partial a_4'} = 3a_4'\,F_k(a_4')$$

(identity (I) with Section 11.21 (e); both sides are polynomials that agree for every a_4'', so the factors of a_4'' agree). For $k = 2$: $\partial(-36a_4'^4 - 120a_4'^2H^2 - 420H^4)/\partial a_4' = -144a_4'^3 - 240a_4'H^2 = 3a_4' \cdot (-48a_4'^2 - 80H^2) = 3a_4'F_2$. The derivative of the constraint is $3a_4'$ times the evolution factor: this is the **constraint propagation** of the record (`a4-equations.json`, key `generalSource`, entry `constraint_propagation`; `python-a4-report.json`, check `bianchi_x4`). Notebook 11c checks (I) exactly for $k = 1, 2, 3$ (In [5]), and (II) both exactly (In [4]) and numerically along a test history (In [9]); In [10] checks (I) numerically as well, along the same history.

What they mean in the field equations (a preview of Chapter 12). In $\sum_k \alpha_k E_{(k)} + \Lambda\delta = \kappa T$, with $T = \mathrm{diag}(p_0, p_3, p_3, p_3, -\rho, p_t, p_t, p_t)$ (in the order $x_0, \ldots, x_7$), identity (I) becomes the conservation of energy $\rho' = -3a_4'(p_3 - p_t)$ (energy flows between 3-space and the extra times when their pressures differ), and identity (II) becomes the condition $p_3 + p_t = 2p_0$ on the pressures (record `a4-equations.json`, key `generalSource`, entries `conservation_reduced` and `algebraic_condition`; Notebook 11c, In [11], checks that the record states both).

11.23 Along the deflating history; an illustrative test history

The linear history (PROVED). Along $a_4 = AHx_4$ we have $a_4' = AH$ and $a_4'' = 0$; the extra times shrink like e^{-AHx_4} (exponential deflation for $A > 0$; the author's history is $A = 1$). With $a_4'' = 0$ the space, extra-time and hidden components coincide (Section 11.21 (e) and identity (II)), and each order has only two different components. In units of H^{2k}:

order	time component $E^{x_4}{}_{x_4}$	the seven others
$k=1$	$3A^2+21$	$15-3A^2$
$k=2$	$-36A^4-120A^2-420$	$12A^4+168A^2-180$
$k=3$	$360A^6+648A^4+1080A^2+2520$	$-72A^6-648A^4-1944A^2+360$

(the components of Section 11.20 with $a_4'=AH$, $a_4''=0$). Every entry is even in A: the history A and its mirror $-A$ give the same tensors (Section 11.21 (g)). Figure 11c.1 draws the six curves for $-3\le A\le 3$ (Notebook 11c, In [6]).

The Lovelock scalars along the linear history. From the record (keys `L1` to `L3` of `lovelock-tensors.json`), in units of H^{2k}:

$$L_{(1)}=12A^2-84,\qquad L_{(2)}=-96A^4-2112A^2+3360,$$
$$L_{(3)}=1152A^6+31104A^4+100224A^2-40320.$$

At the mirror point $A=0$ they are -84, 3360 and -40320. Each has exactly one positive zero. For $k=1$: $12A^2=84$, so $A^2=7$ and $A=\sqrt{7}\approx 2.646$ (divide by 12; take the positive root). For $k=2$, write $u=A^2$:

$$-96u^2-2112u+3360=0 \quad\Longleftrightarrow\quad u^2+22u-35=0$$

(divide by -96: $2112/96=22$ and $3360/96=35$),

$$u=-11+\sqrt{121+35}=-11+\sqrt{156}=2\sqrt{39}-11\approx 1.49000$$

(the formula for the roots of a quadratic, $u=-11\pm\sqrt{11^2+35}$, with the positive root, because $u=A^2\ge 0$; $\sqrt{156}=2\sqrt{39}$), so $A=\sqrt{2\sqrt{39}-11}\approx 1.2207$. For $k=3$, $u^3+27u^2+87u-35=0$ (divide by 1152) has one positive root, which Notebook 11c computes numerically, $A\approx 0.6010$ (In [7], COMPUTED with 15 digits). Figure 11c.2 draws the three scalars with their zeros.

An illustrative test history (ILLUSTRATION, not a solution of any equation). On the linear history $a_4''=0$, so it cannot show where a_4'' enters. Notebook 11c therefore also uses a test history in which the extra times deflate at all times and the deflation speeds up:

$$a_4(x_4)=Hx_4+\tfrac{1}{2}\ln\cosh(Hx_4).$$

Its derivatives, line by line:

$$a_4'=H+\tfrac{1}{2}\cdot\frac{\sinh(Hx_4)}{\cosh(Hx_4)}\cdot H=H\bigl(1+\tfrac{1}{2}\tanh(Hx_4)\bigr)$$

(the derivative of $\ln u$ is u'/u, the derivative of $\cosh t$ is $\sinh t$, and the chain rule gives the factor H; $\sinh/\cosh=\tanh$), and

$$a_4'' = \tfrac{1}{2}H \cdot \frac{H}{\cosh^2(Hx_4)} = \frac{H^2}{2}\operatorname{sech}^2(Hx_4)$$

(the derivative of $\tanh t$ is $1/\cosh^2 t = \operatorname{sech}^2 t$, and the chain rule again). Since $-1 < \tanh < 1$, a_4' lies between $H/2$ and $3H/2$: it is always positive, so the extra times always deflate, slowly in the far past ($a_4' \to H/2$, the linear history with $A = 1/2$) and three times faster in the far future ($a_4' \to 3H/2$, $A = 3/2$). The acceleration a_4'' is a bump of height $H^2/2$ at $x_4 = 0$ ($\operatorname{sech} 0 = 1$). Figure 11c.3 draws the history (Notebook 11c, In [8]). Along it, the components behave as Section 11.21 says (Figure 11c.4, In [9]): the time component depends on a_4' only and moves from one constant to another, for $k = 1$ from $3/4 + 21 = 21.75H^2$ to $27/4 + 21 = 27.75H^2$; the space and extra-time components separate while $a_4'' \neq 0$, by $a_4''F_k$; and the hidden component runs exactly halfway between them. Finally Notebook 11c checks identity (I) along this history with a finite-difference derivative, $f'(t) \approx (f(t+\epsilon) - f(t-\epsilon))/(2\epsilon)$ with $\epsilon = 0.01$, whose error is of the size $\epsilon^2/6$ times the third derivative of the time component; the largest relative deviations are 3.8×10^{-5}, 4.0×10^{-5} and 4.5×10^{-5} for $k = 1, 2, 3$ (COMPUTED, In [10], Figure 11c.5), the size of this error, while the exact identity holds without any error (In [5]).

What the deflation does and does not decide (honesty). The Lovelock tensors are the gravitational side of the field equations. They are the same for A and $-A$: whether the extra times deflate is not decided by them but by the source and the initial data (Chapter 12). This symmetry $A \to -A$ is a property of the metric's geometry; it is NOT the pairing of universes of masses $+m$ and $-m$ of Chapters 18 to 20, and nothing in this chapter says anything about the creation of universes or about matter and antimatter.

11.24 Example: the components and identities along the deflating history

Notebook 11c reads the exact components of the three Lovelock tensors from the Revision record `lovelock-tensors.json`, for the author's metric with a general second function b_4, forms the normalised tensors $E_{(k)}$ and checks that with b_4 they are the components of the Revision's sympy verification (including the two mixed components x_4-x_0 and x_0-x_4, proportional to b_4') and that on the background $b_4 = 1$ they are the components recorded for the field equations of a_4 (`a4-equations.json`); proves with sympy the structure of Section 11.21 (space and extra-time components alike, the constraint free of a_4'', the evolution factors F_k, the hidden component as the mean, evenness in a_4', weight $2k$) and the identities of Section 11.22; draws the components and the scalars along the linear history as functions of A, with the zeros of the scalars; and uses the illustrative test history to show where a_4'' enters and to check identity (I) numerically. It quotes the reports of the field equations of a_4 only by the names of their checks, never by their numbers of checks, so that it stays valid when these reports gain checks. It needs no Rust, takes a few seconds (4.7 seconds when it was built on 2026-10-15; provenance file `Revision/textbook/notebooks/11c_lovelock_components.PROVENANCE.md`), prints 20 PASS lines, draws five figures and ends with the line ALL 20 CHECKS PASSED (notebook 11c).

11.25 How to run Notebook 11c

Step 1. What this notebook does and what it needs.

Notebook 11c (The Lovelock tensors along the deflating history: components and identities) is the file `Revision/textbook/notebooks/11c_lovelock_components.ipynb` of the repository Dirac_claude. It reads the exact components of the three Lovelock tensors of the author's metric from the Revision record, writes the normalised tensors E(1) (the Einstein tensor), E(2) and E(3) as polynomials in H and in the first and second time derivatives of a4, reproduces the components recorded for the field equations of a4, proves with sympy their structure (equal components within ordinary space and within the extra times, a time component without second derivatives, a space minus extra-time difference proportional to the second derivative, a hidden component equal to the mean of the two, evenness in the first derivative, the order of each term) and the two conservation identities, and plots every component and the three Lovelock scalars along the exponentially deflating linear history a4 = A H x4 and along an illustrative test history; it checks again that every check and statement it quotes from the Revision records is there, every check with the verdict PASS; it draws five figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 11c_lovelock_components.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 11c_lovelock_components.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 11c_lovelock_components.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/11c.captions.json`
- `Revision/textbook/figures/11c_1_components_linear_history.png`
- `Revision/textbook/figures/11c_2_lovelock_scalars.png`
- `Revision/textbook/figures/11c_3_test_history.png`
- `Revision/textbook/figures/11c_4_components_test_history.png`
- `Revision/textbook/figures/11c_5_conservation_identity.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of the notebook exist
ALL 20 CHECKS PASSED (notebook 11c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/11c_lovelock_components.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 11c_lovelock_components.ipynb
python -m nbconvert --execute --inplace 11c_lovelock_components.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

11.26 Notebook 11c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/11c_lovelock_components.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the

cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Notebook 11b computed the three Lovelock tensors $P_{(1)}, P_{(2)}, P_{(3)}$ of the
author's metric and found that only their eight diagonal components are not zero.
This notebook studies those components: what they look like, which structure they
have, and how they behave as the extra times deflate. It

- reads the exact components from the Revision record `lovelock-tensors.json` and
  forms the normalised tensors $E_{(k)} = -P_{(k)}/2^{k+1}$ ($E_{(1)}$ is Einstein's
  tensor $G$), and checks that they are the components recorded for the field
  equations of $a_4$ in `Revision/field_equations_a4/a4-equations.json`;
- proves with sympy their structure: the three space components are equal, the three
  extra-time components are equal, the time component contains no $a_4''$, the
  difference of the space and the extra-time component is $a_4''$ times a
  polynomial, the hidden component is the mean of the two, every component is
  unchanged when $a_4'$ changes sign, and every term of order $k$ is $2k$ powers of
  an inverse length;
- derives and checks the two conservation identities (the Bianchi identities) that
  every Lovelock tensor obeys in this metric;
- draws the components and the Lovelock scalars along the exponentially deflating
  history $a_4 = A H x_4$, as functions of $A$; and along an illustrative test
  history in which the deflation speeds up, to show where $a_4''$ enters, with a
  numerical check of the conservation identity along it;
- reads the Revision records once more and checks that every check and statement
  it quotes from them is there, every quoted check with the verdict PASS.

It draws five figures and takes about 15 seconds.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 11c (The Lovelock tensors along the deflating history: components and
identities) is the file `Revision/textbook/notebooks/11c_lovelock_components.ipynb` of
the repository Dirac_claude. It reads the exact components of the three Lovelock tensors
of the author's metric from the Revision record, writes the normalised tensors E(1) (the
Einstein tensor), E(2) and E(3) as polynomials in H and in the first and second time
derivatives of a4, reproduces the components recorded for the field equations of a4,
proves with sympy their structure (equal components within ordinary space and within the
extra times, a time component without second derivatives, a space minus extra-time
difference proportional to the second derivative, a hidden component equal to the mean of
the two, evenness in the first derivative, the order of each term) and the two
conservation identities, and plots every component and the three Lovelock scalars along
the exponentially deflating linear history a4 = A H x4 and along an illustrative test
history; it checks again that every check and statement it quotes from the Revision
records is there, every check with the verdict PASS; it draws five figures. It needs a
```

computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
```

```
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

**Step 4. In every new terminal: activate the environment and go into the repository

folder.**

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 11c_lovelock_components.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 11c_lovelock_components.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 11c_lovelock_components.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/11c.captions.json‘
- ‘Revision/textbook/figures/11c_1_components_linear_history.png‘
- ‘Revision/textbook/figures/11c_2_lovelock_scalars.png‘
- ‘Revision/textbook/figures/11c_3_test_history.png‘
- ‘Revision/textbook/figures/11c_4_components_test_history.png‘
- ‘Revision/textbook/figures/11c_5_conservation_identity.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of the notebook exist
ALL 20 CHECKS PASSED (notebook 11c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/11c_lovelock_components.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs

  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 11c_lovelock_components.ipynb
      python -m nbconvert --execute --inplace 11c_lovelock_components.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 11c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 11c (The Lovelock tensors along the deflating history: components and
# identities) is the file Revision/textbook/notebooks/11c_lovelock_components.ipynb of
# the repository Dirac_claude. It reads the exact components of the three Lovelock
# tensors of the author’s metric from the Revision record, writes the normalised tensors
# E(1) (the Einstein tensor), E(2) and E(3) as polynomials in H and in the first and
# second time derivatives of a4, reproduces the components recorded for the field
# equations of a4, proves with sympy their structure (equal components within ordinary
# space and within the extra times, a time component without second derivatives, a space
# minus extra-time difference proportional to the second derivative, a hidden component
# equal to the mean of the two, evenness in the first derivative, the order of each term)
# and the two conservation identities, and plots every component and the three Lovelock
# scalars along the exponentially deflating linear history a4 = A H x4 and along an
# illustrative test history; it checks again that every check and statement it quotes
# from the Revision records is there, every check with the verdict PASS; it draws five
# figures. It needs a computer with Windows 11, macOS or Linux, an internet connection
# for the installation, the program Git, and Python 3.12 or newer (the notebooks were
# built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6,
# sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
# nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports
# numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and
# runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
```

```
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
```

```
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
```

```
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 11c_lovelock_components.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 11c_lovelock_components.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 11c_lovelock_components.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/11c.captions.json
# - Revision/textbook/figures/11c_1_components_linear_history.png
# - Revision/textbook/figures/11c_2_lovelock_scalars.png
# - Revision/textbook/figures/11c_3_test_history.png
# - Revision/textbook/figures/11c_4_components_test_history.png
# - Revision/textbook/figures/11c_5_conservation_identity.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
```

```
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files of the notebook exist
#     ALL 20 CHECKS PASSED (notebook 11c)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/11c_lovelock_components.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 11c_lovelock_components.ipynb
#     python -m nbconvert --execute --inplace 11c_lovelock_components.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$: $x_1, x_2, x_3$ ordinary space, $x_4$ the time,
  $x_5, x_6, x_7$ the three extra times, $x_0$ the hidden direction.
- **History** $a_4(x_4)$: the function of the time in the author's metric. The
  scale factor of ordinary space is $e^{a_4}$, that of the extra times $e^{-a_4}$
  (times the same factor $\sin^{1/6} z$ of the hidden direction). If $a_4$ grows,
  space **inflates** and the extra times **deflate**.
- **Linear history** $a_4 = A H x_4$ with a constant number $A$: then
  $a_4' = AH$ and $a_4'' = 0$, and the extra times shrink like $e^{-AHx_4}$:
  exponential deflation for $A > 0$.
- $a_4'$, $a_4''$: the first and second derivatives of $a_4$ with respect to the time
  $x_4$. In code they are the symbols `A1` and `A2`.
- **Component** $E^h{}_j$: the number in row $h$ and column $j$ of a tensor;
  $E^{x_1}{}_{x_1}$ is written $E^{x1}_{x1}$ in printed text.
- **Lovelock tensor** $P_{(k)}$, **normalised Lovelock tensor**
  $E_{(k)} = -P_{(k)}/2^{k+1}$, **Lovelock scalar** $L_{(k)}$: built from the
  curvature with the generalized Kronecker delta (Notebooks 11a and 11b).
- **Covariant divergence** $\nabla_h E^h{}_j$: the derivative of a tensor that takes
  the curving of the coordinates into account (through the Christoffel symbols).
  **Bianchi identity**: the statement that it is zero for every Lovelock tensor.
- **Even function**: $f(-u) = f(u)$. **Polynomial in** $u$: a sum of numbers times
  powers $u^n$.
- **Finite difference**: the approximation $f'(t) \approx (f(t + \epsilon) -
  f(t - \epsilon))/(2\epsilon)$ of a derivative.
- **Illustration**: a choice made only to show how a formula behaves; it is not a
  result and not a solution of any equation.
```

Text cell:

```
## 4. The physical and mathematical situation

**The tensors.** For the author's metric (Notebook 11b) the Lovelock tensors
$P_{(k)}{}^h{}_j$, $k = 1, 2, 3$, are diagonal, contain only $H$, $a_4'$ and
$a_4''$, and do not depend on $x_0$. The field equations of $a_4$ (chapter 12) use
the normalised tensors
```

```
$$E_{(k)}{}^h{}_j = -\frac{1}{2^{k+1}}\, P_{(k)}{}^h{}_j ,\qquad
  \sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda\,\delta^\mu_\nu
  = \kappa\, T^\mu{}_\nu ,$$

with $E_{(1)} = G$, Einstein's tensor. The independent components are
$E^{x1}_{x1}$ (equal to $E^{x2}_{x2}$ and $E^{x3}_{x3}$: ordinary space),
$E^{x4}_{x4}$ (the time), $E^{x5}_{x5}$ (equal to $E^{x6}_{x6}$ and $E^{x7}_{x7}$:
the extra times) and $E^{x0}_{x0}$ (the hidden direction).

**The two conservation identities, derived line by line.** Every Lovelock tensor has
zero covariant divergence (Lovelock's theorem; the Revision checked it exactly). For
a diagonal tensor that depends only on $x_4$ the divergence is

$$\nabla_h P^h{}_j = \partial_h P^h{}_j + \sum_{h,m} \Gamma^h{}_{hm} P^m{}_j
  - \sum_{h,m} \Gamma^m{}_{hj} P^h{}_m .$$

Take $j = x_4$. The first term is $\partial_4 P^4{}_4$ (only $h = x_4$ survives,
because $P^h{}_4 = 0$ for $h \ne x_4$). In the second term only $m = x_4$ survives:
$\sum_h \Gamma^h{}_{h4} P^4{}_4$. In the third, $P^h{}_m$ is diagonal, so $m = h$:
$\sum_h \Gamma^h{}_{h4} P^h{}_h$. Hence

$$\nabla_h P^h{}_4 = \partial_4 P^4{}_4 + \sum_h \Gamma^h{}_{h4}
  \big(P^4{}_4 - P^h{}_h\big).$$

The Christoffel symbols of the metric (Notebook 11b) are $\Gamma^h{}_{h4} = a_4'$ for
the three space directions, $-a_4'$ for the three extra times, and 0 for $x_4$ and
$x_0$. So the sum is $3a_4'(P^4{}_4 - P^1{}_1) - 3a_4'(P^4{}_4 - P^5{}_5) =
-3a_4'(P^1{}_1 - P^5{}_5)$, and the identity reads

$$\frac{d}{dx_4} E^{x4}{}_{x4} = 3\, a_4'\, \big(E^{x1}{}_{x1} - E^{x5}{}_{x5}\big).
  \qquad (\text{I})$$

Take $j = x_0$. Nothing depends on $x_0$, and the same steps give
$\sum_h \Gamma^h{}_{h8}(P^8{}_8 - P^h{}_h)$ with $\Gamma^h{}_{h8} = H \cot z$ for the
three space and the three extra-time directions, 0 for $x_4$, and the term $h = x_0$
is zero because $P^8{}_8 - P^8{}_8 = 0$. So $3H\cot z\,(2P^8{}_8 - P^1{}_1 -
P^5{}_5) = 0$, that is

$$E^{x0}{}_{x0} = \tfrac12 \big(E^{x1}{}_{x1} + E^{x5}{}_{x5}\big).
  \qquad (\text{II})$$

The divergences along $x_1, x_2, x_3, x_5, x_6, x_7$ vanish because nothing depends
on these coordinates and the tensors are diagonal. In the field equations (I) becomes
the conservation of energy, $\rho' = -3a_4'(p_3 - p_t)$, and (II) the condition
$p_3 + p_t = 2p_0$ on the pressures (chapter 12), on the background $b_4 = 1$
of the author's metric of 2026-10-14 (with a changing second function $b_4(x_4)$ the
tensors also have the mixed components $x_4$-$x_0$ and $x_0$-$x_4$, proportional
to $b_4'$; section 5).

**Status.** The components are PROVED by exact computation (Revision records); the
structure and the identities are PROVED here with sympy; the test history of
section 9 is an ILLUSTRATION, not a solution of the field equations.
```

Text cell:

5. The components, from the Revision record

The next cell reads ‘lovelock-tensors.json‘, which lists every component of $P_{(k)}$, for the author’s metric with a general second function $b_4(x_4)$, as exact monomials ‘[numerator, denominator, [e_H, e_a4’, e_a4’’, e_a4’’’, e_a4’’’’, e_E, e_S, e_C, e_Q, e_b4’, e_b4’’, e_b4’’’, e_b4’’’’]]‘ (the exponents of H, of the four derivatives of a_4, of e^{a_4}, of $\sin^{1/3} z$, of $\cot z$, of $Q = b_4^{1/2}$ and of the four derivatives of b_4). It rebuilds each component as a sympy expression in ‘H‘, ‘A1‘ ($a_4’$), ‘A2‘ ($a_4’’$), ‘c‘ ($\cot z$) and ‘B0‘, ‘B1‘, ‘B2‘ (b_4, $b_4’$, $b_4’’$); if any other exponent were not zero the cell would stop, so the components are free of e^{a_4}, of $\sin^{1/3} z$ and of higher derivatives. With b_4 exactly two components off the diagonal are not zero, x_4-x_0 and x_0-x_4, and both contain $b_4’$. From here on the notebook works on the background $b_4 = 1$ ($b_4’ = b_4’’ = 0$) of the Revision records: ‘P‘ holds the components there, ‘P_B4‘ those with a general b_4. It forms $E_{(k)} = -P_{(k)}/2^{k+1}$ and prints the four independent components of each order at $b_4 = 1$.

## 6. The structure of the components

The next cell proves, for $k = 1, 2, 3$, with exact sympy algebra:

1. $E^{x1}_{x1} = E^{x2}_{x2} = E^{x3}_{x3}$ and $E^{x5}_{x5} = E^{x6}_{x6} =
   E^{x7}_{x7}$: the three space directions are alike, and so are the three extra
   times.
2. $E^{x4}_{x4}$ and $E^{x0}_{x0}$ contain no $a_4''$ (‘expr.has(A2)‘ is False): the
```

```
   time component of the field equations is a condition on $a_4'$ only (a
   constraint), not an equation for its change.
3. $E^{x1}_{x1} - E^{x5}_{x5} = a_4''\, F_k(a_4')$ with a polynomial $F_k$ that
   contains no $a_4''$ (`sp.cancel` divides exactly, and the quotient must be free
   of `A2`): this difference is the only place where $a_4''$ appears, so it is the
   equation that decides how $a_4$ changes (the evolution equation of chapter 12).
   The record `a4-equations.json` lists
   $F = \alpha_1 F_1 + \alpha_2 F_2 + \alpha_3 F_3$ in its entry `evolution_F`; the
   cell compares the coefficient of each $\alpha_k$.
4. $E^{x0}_{x0} = \tfrac12 (E^{x1}_{x1} + E^{x5}_{x5})$: identity (II).
5. Every component is even in $a_4'$: replacing $a_4'$ by $-a_4'$ changes nothing.
   Inflating ordinary space with deflating extra times ($a_4' > 0$) and the reverse
   ($a_4' < 0$) give the same components: deflation is a choice of sign that these
   tensors do not select.
6. Every term of $E_{(k)}$ has the **weight** $2k$, where $H$ and $a_4'$ count 1 and
   $a_4''$ counts 2 (each is one inverse length per count): order $k$ has the
   dimension $1/\text{length}^{2k}$. So the three orders can be added in one field
   equation only with constants $\alpha_k$ of different dimensions, for example
   $\alpha_k = w_k / H^{2k - 2}$ with pure numbers $w_k$.
```

## 7. The conservation identity along the time

Identity (I) of section 4 says $\frac{d}{dx_4} E^{x4}_{x4} = 3a_4'(E^{x1}_{x1} -
E^{x5}_{x5})$. The time component depends on $x_4$ only through $a_4'$, so by the
chain rule $\frac{d}{dx_4} E^{x4}_{x4} = \frac{\partial E^{x4}_{x4}}{\partial a_4'}
\, a_4''$. The next cell checks the identity exactly for $k = 1, 2, 3$ with
`sp.diff(..., A1) * A2`. With section 6 it says
$\partial E^{x4}_{x4}/\partial a_4' = 3 a_4' F_k(a_4')$: the derivative of the
constraint is $3a_4'$ times the evolution factor, the "constraint propagation" of
the Revision record. The cell also checks the factorisation
$E^{x4}_{x4} - E^{x0}_{x0} = 6(a_4'^2 + H^2)\, V_k(a_4')$, with the polynomials $V_1 =
1$, $V_2 = -8(a_4'^2 + 5H^2)$, $V_3 = 72(a_4'^4 + 2a_4'^2 H^2 + 5H^4)$, which the
Revision record of the field equations uses for the linear history
(check `linear_member_vacuum_factor`).
```

## 8. Along the exponentially deflating history $a_4 = A H x_4$

On the linear history $a_4' = AH$ and $a_4'' = 0$. Then every component is $H^{2k}$
times a polynomial in $A$, and the plots below show $E_{(k)}{}^h{}_h / H^{2k}$
against $A$ from $-3$ to $3$ ($A > 0$: the extra times deflate exponentially, the
author's case; $A < 0$: they would inflate; $A = 0$, where $a_4$ is constant, is the
mirror point between the two). Because $a_4'' = 0$, the space, extra-time and
hidden components coincide (section 6, items 3 and 4), so each panel has two curves:
the time component $E^{x4}_{x4}$ and the common component of the seven other
directions. `sp.lambdify` turns a sympy expression into a numpy function that can
be evaluated on an array of values of $A$. The check confirms that the two curves
are mirror-symmetric about $A = 0$.
```

In [6]:

```
A = np.linspace(-3.0, 3.0, 601)  # values of A
LINEAR = {H: 1, A2: 0}  # H = 1 (units of H) and a4'' = 0; then a4' = A

## 9. An illustrative test history in which the deflation speeds up

On the linear history $a_4'' = 0$, so it cannot show where $a_4''$ enters. The next
cells therefore use a test history in which the extra times deflate exponentially
at ALL times, slowly in the far past and three times faster in the far future:
```

```
$$a_4(x_4) = H x_4 + \tfrac12 \ln\cosh(H x_4),\qquad
  a_4' = H\big(1 + \tfrac12 \tanh(H x_4)\big),\qquad
  a_4'' = \tfrac{H^2}{2}\,\mathrm{sech}^2(H x_4).$$

(The derivative of $\ln\cosh t$ is $\tanh t$, and that of $\tanh t$ is
$\mathrm{sech}^2 t = 1/\cosh^2 t$.) Since $-1 < \tanh < 1$, $a_4'$ lies between
$H/2$ and $3H/2$ and is always positive: the extra times always deflate. For
$x_4 \to -\infty$, $a_4' \to H/2$ (the linear history with $A = 1/2$); for
$x_4 \to +\infty$, $a_4' \to 3H/2$ ($A = 3/2$); $a_4''$ is largest, $H^2/2$, at
$x_4 = 0$, where the deflation speeds up. This history is an ILLUSTRATION chosen
only to show how the components depend on $a_4'$ and $a_4''$; it is not a solution
of the field equations, and no source is attached to it. The next cell checks the
two derivatives with sympy and draws the history.

## 10. The Revision records quoted in this notebook

This notebook quotes check names and statements from the Revision records. The
components themselves were compared with ‘lovelock-tensors.json‘,
‘python-lovelock-report.json‘ and ‘a4-equations.json‘ in section 5. The next cell
reads the records once more and checks the rest of what the text quotes, so that a
later change of a record cannot pass unnoticed:

- every check quoted from the report ‘python-a4-report.json‘ of the field equations
  of $a_4$ and from the Rust report ‘lovelock-report.json‘ is present with the
  verdict PASS;
- the record ‘a4-equations.json‘ states the two consequences of the conservation
  identities quoted in section 4 (its entries ‘conservation_reduced‘ and
  ‘algebraic_condition‘) and the constraint propagation quoted in section 7 (its
  entry ‘constraint_propagation‘).

The function ‘verdicts(path)‘ returns, for one report, a dictionary from the name of
each check to its verdict. The reports store their checks in one of two forms: a
list of entries, each with a ‘name‘ and a ‘verdict‘, or a dictionary from the name to
an entry whose field ‘passed‘ is true or false; the function reads both.
```

In [11]:

```
def verdicts(path):
    """{check name: "PASS" or "FAIL"} of the Revision report at ‘path‘."""
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))

## 11. What this notebook showed

- The normalised Lovelock tensors of the author's metric are diagonal polynomials in
  $H$, $a_4'$ and $a_4''$, for example Einstein's tensor
  $E^{x1}_{x1} = -3a_4'^2 + a_4'' + 15H^2$, $E^{x4}_{x4} = 3a_4'^2 + 21H^2$,
  $E^{x5}_{x5} = -3a_4'^2 - a_4'' + 15H^2$, $E^{x0}_{x0} = -3a_4'^2 + 15H^2$; all
  three orders equal the components recorded for the field equations of $a_4$.
- Their structure (PROVED): space components equal, extra-time components equal;
  time and hidden components free of $a_4''$; the space minus extra-time difference
  is $a_4''$ times $F_1 = 2$, $F_2 = -16(3a_4'^2 + 5H^2)$, $F_3 = 144(5a_4'^4 +
  6a_4'^2H^2 + 5H^4)$; the hidden component is the mean of the space and extra-time
  components; everything is even in $a_4'$, so deflation of the extra times is not
  selected by these tensors; order $k$ has the dimension $1/\text{length}^{2k}$.
- The two conservation identities, $\frac{d}{dx_4}E^{x4}_{x4} = 3a_4'(E^{x1}_{x1} -
  E^{x5}_{x5})$ and $E^{x0}_{x0} = \frac12(E^{x1}_{x1} + E^{x5}_{x5})$, hold exactly
  for every order and were confirmed numerically along a test history.
- On the exponentially deflating linear history $a_4 = AHx_4$ only two different
  components remain (time, and all the others), even functions of $A$; the test
  history (an illustration only) shows that $a_4''$ separates the space and
  extra-time components while the hidden one stays halfway between them.
- Every check and statement that the notebook quotes from the Revision records is
  present in them, every quoted check with the verdict PASS.
```

11.27 Line-by-line walk-through of Notebook 11c

The notebook has 12 code cells, In [1] to In [12]. As in Sections 11.9 and 11.19, every line or small group of lines is quoted and explained; docstrings are left out where the explanation repeats them, and long captions are shortened to ... (they are printed in full under the figures in Section 11.26).

In [1], the set-up cell. It is the set-up cell of Notebook 11a, explained line by line in Section 11.9 under In [1], with three differences: its comment lines are the run instructions of Notebook

11c (Section 11.25); its line `NOTEBOOK_ID = "11c" # this notebook: chapter 11, example c` names this notebook; and, because this notebook runs no Rust program, the two lines `import shutil` and `import subprocess` and the helper `rust_program` are absent. It prints Set-up of notebook 11c complete: repository folder found, helpers defined.

In [2], the components from the Revision record.

```
import re  # regular expressions: rewrites the record's names

import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra

H, A1, A2 = sp.symbols("H A1 A2")  # H, a4' and a4''
B0, B1, B2, c = sp.symbols("B0 B1 B2 c")  # b4, b4', b4'' and cot z
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
tensors = json.loads(repository_file(
    "Revision/gkd_lovelock/results/lovelock-tensors.json").read_text(encoding="utf-8"))
```

`re` (regular expressions, used in In [7] to rewrite the names of the record), numpy and sympy are loaded; three sympy symbols stand for H, a_4' and a_4'', and four more, `B0`, `B1`, `B2` and `c`, for b_4, b_4', b_4'' and $\cot z$; `NAMES` lists the coordinate names; and the Rust record of the Lovelock tensors is read as JSON (Section 11.9 explains `repository_file`, `read_text` and `json.loads`).

```
def from_monomials(monomials):
    total = sp.Integer(0)
    for numerator, denominator, e in monomials:
        if e[3] or e[4] or e[5] or e[6] or e[11] or e[12]:
            raise ValueError("the component contains a3, a4 derivatives, e^a4, "
                             "sin^(1/3) z or higher derivatives of b4")
        monomial = (H ** e[0] * A1 ** e[1] * A2 ** e[2] * c ** e[7]
                    * B0 ** sp.Rational(e[8], 2) * B1 ** e[9] * B2 ** e[10])
        total += sp.Rational(numerator, denominator) * monomial
    return total
```

A component of the record is a list of monomials, each a numerator, a denominator and thirteen exponents (of H, a_4', a_4'', a_4''', a_4'''', e^{a_4}, $\sin^{1/3} z$, $\cot z$, $Q = b_4^{1/2}$, b_4', b_4'', b_4''', b_4''''). The function (docstring left out) rebuilds the component as a sympy expression, for a general b_4. If one of the exponents of a_4''', a_4'''', e^{a_4}, $\sin^{1/3} z$, b_4''' or b_4'''' were not 0, the notebook would stop. Since it does not stop, every component is free of e^{a_4}, of $\sin^{1/3} z$ and of higher derivatives (Section 11.20). Each monomial is the exact fraction (`sp.Rational`) times $H^{e_0} a_4'^{e_1} a_4''^{e_2} \cot^{e_7} z\, b_4^{e_8/2} b_4'^{e_9} b_4''^{e_{10}}$.

```

     for k in (1, 2, 3)}
```

`P_B4[k][h, j]` is the component ${P_{(k)}}^h{}_j$ with a general b_4, built for all 64 pairs (`enumerate(NAMES)` gives each number with its name, used for the record's keys such as `"x1,x1"`). `BACKGROUND` is the substitution $b_4 = 1$, $b_4' = b_4'' = 0$, and `P[k][h, j]` the component there. The first check requires that with b_4 exactly the two mixed components x_4-x_0 and x_0-x_4 are nonzero off the diagonal, both containing b_4', and that at $b_4 = 1$ no component contains $\cot z$. First PASS line. `E[k]` holds the normalised components $E_{(k)} = -P_{(k)}/2^{k+1}$ at $b_4 = 1$, multiplied out.

```
for k in (1, 2, 3):
    for h in (1, 4, 5, 0):  # x1, x4, x5, x0
        say(f"E({k})^{NAMES[h]}_{NAMES[h]} = {E[k][h, h]}")
check(all(E[k][h, j] == 0 for k in (1, 2, 3) for h in range(8) for j in range(8)
          if h != j),
      "at b4 = 1 every off-diagonal component of E(1), E(2), E(3) is zero, x4-x0 "
      "included")
```

The four independent components of each order are printed: twelve lines that are exactly the list of Section 11.20 (sympy writes `A1**2` for $a_4'^2$). The check confirms that at $b_4 = 1$ every off-diagonal component is zero (Section 11.21 (a)). Second PASS line.

In [3], against the other records.

```
a4_record = json.loads(repository_file(
    "Revision/field_equations_a4/a4-equations.json").read_text(encoding="utf-8"))
WOLFRAM_NAMES = {"ad1": A1, "ad2": A2, "H": H}

def from_text(text):
    return sp.sympify(text.replace("^", "**"), locals=WOLFRAM_NAMES)
```

The record of the field equations of a_4 is read. It writes formulas in Wolfram's input notation, with `ad1` for a_4', `ad2` for a_4'' and `^` for powers; `from_text` (docstring left out) replaces `^` by `**` and reads the text with these names bound to the notebook's symbols.

```
same = True
for k in (1, 2, 3):
    listed = a4_record["lovelockTensors"][f"E{k}"]
    for key, (h, j) in (("x1x1", (1, 1)), ("x4x4", (4, 4)), ("x5x5", (5, 5)),
                        ("x0x0", (0, 0)), ("x4x0", (4, 0)), ("x0x4", (0, 4))):
        same = same and sp.expand(from_text(listed[key]["input"]) - E[k][h, j]) == 0
check(same, "E(1), E(2), E(3) equal the components recorded for the a4 equations",
      record="Revision/field_equations_a4/reports/python-a4-report.json, check "
             "json_lovelock_components")
```

For each order the record's entry `lovelockTensors` lists six components, the four independent diagonal ones and the two x_4-x_0 ones (which are 0). Each must equal the notebook's component exactly. Third PASS line.

```
checker = json.loads(repository_file(
    "Revision/gkd_lovelock/results/python-lovelock-report.json").read_text(
        encoding="utf-8"))
independent = checker["independentResults"]
same = all(
    sp.simplify(sp.sympify(text, locals={"A1": A1, "A2": A2, "H": H, "B0": B0,
                                         "B1": B1, "B2": B2, "c": c})
                - P_B4[k][NAMES.index(key.split(",")[0]),
                          NAMES.index(key.split(",")[1])]) == 0
    for k in (1, 2, 3) for key, text in independent[f"P{k}_mixed_nonzero"].items())
check(same and all(len(independent[f"P{k}_mixed_nonzero"]) == 10 for k in (1, 2, 3)),
      "P(1), P(2), P(3) equal the independent sympy results with b4 (10 nonzero "
      "components each)",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "independentResults")
```

The Revision's sympy verification stores its own, independently computed nonzero components in the entry `independentResults`, under keys such as `"x1,x1"`; `key.split(",")` cuts a key into the two names. These are computed with a general b_4, in the symbols `B0`, `B1`, `B2` and `c`. Every one must equal the notebook's $P_{(k)}$ with b_4 exactly (`sp.simplify` of the difference must be 0), and there must be exactly 10 for each order: the eight diagonal ones and the two mixed ones. Fourth PASS line.

In [4], the structure.

```
u = sp.Symbol("u")  # an auxiliary number used to test the weights
F = {}  # k -> F_k(a4')
alphas = sp.symbols("alpha1 alpha2 alpha3")  # the constants of the a4 equations
recorded_F = sp.sympify(
    a4_record["generalSource"]["evolution_F"]["input"].replace("^", "**"),
    locals={"ad1": A1, "H": H, "alpha1": alphas[0], "alpha2": alphas[1],
            "alpha3": alphas[2]})
```

The symbol `u` will scale the components; `F` will hold the evolution factors; the three Lovelock constants $\alpha_1, \alpha_2, \alpha_3$ are symbols; and the record's evolution factor $F = \alpha_1 F_1 + \alpha_2 F_2 + \alpha_3 F_3$ (key `generalSource`, entry `evolution_F`) is read.

```
structure = {name: True for name in ("alike", "constraint", "evolution", "mean",
                                     "even", "weight")}
```

A dictionary of six true/false flags, one for each property of Section 11.21; each starts true and is combined below with the result for every order.

```
for k in (1, 2, 3):
    e = E[k]
```

```
    structure["alike"] &= (e[1, 1] == e[2, 2] == e[3, 3]
                           and e[5, 5] == e[6, 6] == e[7, 7])
    structure["constraint"] &= not e[4, 4].has(A2) and not e[0, 0].has(A2)
```

`&=` combines a flag with a new result by AND: it stays true only if both are true. "alike": the three space components are equal and the three extra-time components are equal (Section 11.21 (b)). "constraint": the time and the hidden component do not contain a_4'' (`expr.has(A2)` is true when the symbol occurs; parts (d) and (f)).

```
    F[k] = sp.factor(sp.cancel((e[1, 1] - e[5, 5]) / A2))
    structure["evolution"] &= (not F[k].has(A2)
                               and sp.expand(F[k] - recorded_F.coeff(alphas[k - 1]))
                               == 0)
```

The space minus the extra-time component, divided by a_4'': `sp.cancel` divides exactly and `sp.facto r` writes the result as a product. It must be free of a_4'' (part (e)) and equal to the coefficient of α_k in the record's F (`.coeff(alphas[k - 1])`; Python counts the list `alphas` from 0).

```
    structure["mean"] &= sp.expand(e[0, 0] - (e[1, 1] + e[5, 5]) / 2) == 0
    structure["even"] &= all(sp.expand(e[h, h].subs(A1, -A1) - e[h, h]) == 0
                             for h in range(8))
```

"mean": identity (II) of Section 11.22. "even": replacing a_4' by $-a_4'$ (`.subs(A1, -A1)`) changes no diagonal component (part (g)).

```
    weighted = {h: sp.expand(e[h, h].subs({H: u * H, A1: u * A1, A2: u ** 2 * A2}))
                for h in range(8)}
    structure["weight"] &= all(sp.expand(weighted[h] - u ** (2 * k) * e[h, h]) == 0
                               for h in range(8))
    report(f"F_{k}(a4') = (E({k})^x1_x1 - E({k})^x5_x5) / a4''", F[k])
```

"weight": replacing H, a_4', a_4'' by uH, ua_4', u^2a_4'' must multiply each component by u^{2k}, which is true exactly when every term has the weight $2k$ (part (h)). The RESULT lines print $F_1 = 2$, $F_2 = -16(3a_4'^2 + 5H^2)$ and $F_3 = 144(5a_4'^4 + 6a_4'^2H^2 + 5H^4)$.

```
check(structure["alike"], "space components equal, extra-time components equal")
check(structure["constraint"], "the x4 and x0 components contain no a4''")
check(structure["evolution"],
      "E^x1_x1 - E^x5_x5 = a4'' F_k(a4') with F_1 = 2, F_2 = -16 (3 a4'^2 + 5 H^2), "
      "F_3 = 144 (5 a4'^4 + 6 a4'^2 H^2 + 5 H^4)",
      record="Revision/field_equations_a4/reports/python-a4-report.json, check "
             "evolution_factorises (a4-equations.json, evolution_F)")
check(structure["mean"], "E^x0_x0 is the mean of E^x1_x1 and E^x5_x5 (identity II)")
check(structure["even"] and structure["weight"],
      "every component is even in a4' and of weight 2k (dimension 1/length^(2k))")
```

Five checks, one per flag (evenness and weight together). PASS lines five to nine.

In [5], identity (I) and the factor V_k.

```
V = {1: sp.Integer(1), 2: -8 * (A1 ** 2 + 5 * H ** 2),
     3: 72 * (A1 ** 4 + 2 * A1 ** 2 * H ** 2 + 5 * H ** 4)}
identity_I = all(
    sp.expand(sp.diff(E[k][4, 4], A1) * A2 - 3 * A1 * (E[k][1, 1] - E[k][5, 5])) == 0
    for k in (1, 2, 3))
```

`V` holds the three factors V_k of Section 11.21. Identity (I): the time component depends on x_4 only through a_4', so its derivative is $\partial E^{x_4}{}_{x_4}/\partial a_4'$ times a_4'' (the chain rule; `sp.diff(..., A1)` differentiates with respect to the symbol a_4'), and this must equal $3a_4'(E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5})$ for every order.

```
check(identity_I, "d/dx4 E^x4_x4 = 3 a4' (E^x1_x1 - E^x5_x5) for k = 1, 2, 3 "
                  "(identity I)",
      record="Revision/field_equations_a4/reports/python-a4-report.json, check "
             "bianchi_x4; Revision/gkd_lovelock/results/lovelock-report.json, checks "
             "k1_divergence_free, k2_divergence_free and k3_divergence_free")
factor_ok = all(sp.expand(E[k][4, 4] - E[k][0, 0] - 6 * (A1 ** 2 + H ** 2) * V[k]) == 0
                for k in (1, 2, 3))
check(factor_ok, "E^x4_x4 - E^x0_x0 = 6 (a4'^2 + H^2) V_k for k = 1, 2, 3",
      record="Revision/field_equations_a4/reports/python-a4-report.json, check "
             "linear_member_vacuum_factor")
```

The two checks: identity (I) holds exactly, and the factorisation $E^{x_4}{}_{x_4} - E^{x_0}{}_{x_0} = 6(a_4'^2 + H^2)V_k$ holds for $k = 1, 2, 3$. PASS lines ten and eleven.

In [6], the linear history (Figure 11c.1).

```
A = np.linspace(-3.0, 3.0, 601)  # values of A
LINEAR = {H: 1, A2: 0}  # H = 1 (units of H) and a4'' = 0; then a4' = A

def on_linear_history(expr):
    function = sp.lambdify(A1, expr.subs(LINEAR), "numpy")
    return np.broadcast_to(function(A), A.shape).astype(float)
```

`np.linspace(-3.0, 3.0, 601)` is the array of 601 equally spaced values from -3 to 3. On the linear history, with $H = 1$, $a_4' = A$ and $a_4'' = 0$. `on_linear_history` (docstring left out) substitutes these values, and `sp.lambdify` turns the remaining expression in `A1` into a numpy function that is evaluated on the whole array at once. `np.broadcast_to(..., A.shape)` makes a constant result (an expression without A) into an array of the same length, and `.astype(float)` into decimal numbers.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.0))
symmetric = True
for ax, k in zip(axes, (1, 2, 3)):
    time_part = on_linear_history(E[k][4, 4])
    other_part = on_linear_history(E[k][1, 1])
    symmetric &= np.allclose(time_part, time_part[::-1]) and np.allclose(
        other_part, other_part[::-1])
```

One panel per order. `time_part` is ${E^{x_4}}_{x_4}$ and `other_part` the common value of the seven other components along the history. `[::-1]` reverses an array, which maps the value at A to the value at $-A$ (the grid is symmetric about 0), and `np.allclose` tests that two arrays agree up to rounding: both curves must be mirror-symmetric.

```
    ax.plot(A, time_part, label="$E^{x_4}{}_{x_4}$ (time)")
    ax.plot(A, other_part, "--", label="$E^{x_1}{}_{x_1} = E^{x_5}{}_{x_5} = "
                                       "E^{x_0}{}_{x_0}$")
    ax.axvline(0.0, color="0.5", lw=0.8)
    ax.axhline(0.0, color="0.5", lw=0.8)
    ax.set_xlabel("$A = a_4^{\\prime}/H$")
    ax.set_ylabel(f"$E_{{({k})}}$ in units of $H^{{{2 * k}}}$")
    ax.set_title(f"order k = {k}")
    ax.legend(fontsize=7, loc="best")
```

The two curves (solid and dashed), grey lines at $A = 0$ and at the value 0, axis titles, title and legend (`loc="best"` lets matplotlib choose a free corner).

```
fig.tight_layout()
save_figure(fig, "components_linear_history",
            "The normalised Lovelock tensors $E_{(1)}$ (Einstein), $E_{(2)}$ and "
            ...)
check(symmetric, "on the linear history every curve is symmetric under A -> -A")
```

The figure is saved and the symmetry checked. Twelfth PASS line.

What Figure 11c.1 shows. Three panels, one per order, against A from -3 to 3 in units of H^{2k}. For $k = 1$ the time component $3A^2 + 21$ is a parabola opening upward from 21, and the other component $15 - 3A^2$ one opening downward from 15, crossing 0 at $A = \pm\sqrt{5}$. For $k = 2$ the curves open the other way, and the dashed one crosses 0 at $A = \pm 1$ ($12 + 168 - 180 = 0$). For $k = 3$ both grow like A^6. Every curve is a mirror image of itself about $A = 0$: deflating ($A > 0$) and inflating ($A < 0$) extra times give the same tensors.

In [7], the Lovelock scalars (Figure 11c.2).

```
L_TEXT = {k: re.sub(r"Derivative\[(\d)\]\[b4\]\[x4\]", r"B\1",
                    re.sub(r"Derivative\[(\d)\]\[a4\]\[x4\]", r"A\1",
                           tensors[f"L{k}"])).replace("b4[x4]", "B0")
          for k in (1, 2, 3)}
L = {k: sp.expand(sp.sympify(L_TEXT[k].replace("^", "**"),
                             locals={"A1": A1, "A2": A2, "H": H, "B0": B0, "B1": B1,
                                     "B2": B2}).subs(BACKGROUND))
     for k in (1, 2, 3)}  # the scalars at b4 = 1
fig, axes = plt.subplots(1, 3, figsize=(12.0, 3.8))
zeros = {}
```

The three scalars of the record (keys `L1` to `L3`, in Mathematica text, with b_4) are read as sympy expressions: `re.sub` writes the derivatives of a_4 as `A1`, `A2` and those of b_4 as `B1`, `B2`, `b4[x4]` becomes `B0`, and `.subs(BACKGROUND)` puts $b_4 = 1$. Three panels and an empty dictionary for the zeros.

```
for ax, k in zip(axes, (1, 2, 3)):
    values = on_linear_history(L[k])
    roots = sp.Poly(L[k].subs(H, 1), A1).nroots(n=15)  # every root, numerically
    zeros[k] = [float(r) for r in roots if r.is_real and r > 0]
    listed = ", ".join(f"{r:.4f}" for r in zeros[k])  # the zeros, 4 decimals
    say(f"L({k}) = {L[k]}")
    report(f"positive zero of L({k}) on the linear history (and minus it), A", listed)
```

For each order the scalar is evaluated along the history. `sp.Poly(..., A1).nroots(n=15)` computes all roots of the polynomial in A (with $H = 1$) numerically to 15 digits, including complex ones; the comprehension keeps the real positive roots. The output lines print each scalar and its positive zero: $A = 2.6458$, 1.2207 and 0.6010 (Section 11.23 derives the first two exactly: $\sqrt{7}$ and $\sqrt{2\sqrt{39} - 11}$).

```
    ax.plot(A, values, color="tab:green")
    for r in zeros[k]:
        ax.plot([r, -r], [0.0, 0.0], "o", color="black", markersize=4)
    ax.axhline(0.0, color="0.5", lw=0.8)
    ax.axvline(0.0, color="0.5", lw=0.8)
    ax.set_xlabel("$A = a_4^{\\prime}/H$")
    ax.set_ylabel(f"$L_{{({k})}}$ in units of $H^{{{2 * k}}}$")
    ax.set_title(f"Lovelock scalar of order {k}")
```

The green curve, black dots at the zero and at its mirror image, grey lines, axis titles and title.

```
    if k == 3:  # a magnified view of the middle, where the zeros of L(3) lie
        zoom = ax.inset_axes([0.30, 0.42, 0.42, 0.42])  # [left, bottom, width, height]
        near = np.abs(A) <= 1.0  # the values of A between -1 and 1
        zoom.plot(A[near], values[near], color="tab:green")
        zoom.axhline(0.0, color="0.5", lw=0.8)
        for r in zeros[k]:
            zoom.plot([r, -r], [0.0, 0.0], "o", color="black", markersize=3)
        zoom.tick_params(labelsize=6)
        zoom.set_title("magnified: $-1 \\leq A \\leq 1$", fontsize=7)
```

For the third order the scale of the whole panel (millions) hides the dip near $A = 0$, so a small panel inside the big one (`ax.inset_axes`, placed by its left edge, bottom edge, width and height as fractions of the big panel) shows the part $-1 \leq A \leq 1$. `near` is a true/false array, and `A[near]` keeps the values where it is true.

```
fig.tight_layout()
save_figure(fig, "lovelock_scalars",
            "The Lovelock scalars $L_{(1)} = 2R = 12 a_4^{\\prime 2} - 84 H^2$, "
            ...)
check(all(len(zeros[k]) == 1 for k in (1, 2, 3))
      and abs(zeros[1][0] - float(sp.sqrt(7))) < 1e-12
      and L[1].subs({A1: 0, H: 1}) == -84 and L[2].subs({A1: 0, H: 1}) == 3360
      and L[3].subs({A1: 0, H: 1}) == -40320,
      "each scalar has one positive zero, L(1) at A = sqrt(7); at A = 0 the scalars "
      "are -84, 3360, -40320")
```

The caption written into the figure includes the computed zeros (the f-strings of the caption insert them, rounded to three decimals). The check: exactly one positive zero for each order, the first at $\sqrt{7}$ to 12 digits, and the values -84, 3360, -40320 at $A = 0$. Thirteenth PASS line.

What Figure 11c.2 shows. $L_{(1)} = 12A^2 - 84$ is a parabola with its lowest point -84 at $A = 0$ and zeros at $\pm\sqrt{7}$. $L_{(2)}$ opens downward from its highest point 3360 and crosses 0 at ± 1.221. $L_{(3)}$ has a shallow dip to -40320 at $A = 0$, visible only in the magnified inset, crosses 0 at ± 0.601 and then grows to about 4×10^6 at $A = \pm 3$.

In [8], the test history (Figure 11c.3).

```
t = sp.Symbol("t")  # t = H x4 (the time in units of 1/H); H = 1 below
history = t + sp.log(sp.cosh(t)) / 2
first = sp.diff(history, t)  # a4' (with H = 1)
second = sp.diff(history, t, 2)  # a4''
check(sp.simplify(first - (1 + sp.tanh(t) / 2)) == 0
      and sp.simplify(second - sp.sech(t) ** 2 / 2) == 0,
      "the test history has a4' = 1 + tanh/2 > 0 and a4'' = sech^2/2 (H = 1)")
```

The illustrative history of Section 11.23 with $H = 1$, in the variable $t = Hx_4$. sympy differentiates it once and twice (`sp.diff(history, t, 2)`), and the check confirms the derivatives derived by hand: $1 + \frac{1}{2}\tanh t$ and $\frac{1}{2}\mathrm{sech}^2 t$. Fourteenth PASS line.

```
times = np.linspace(-6.0, 6.0, 1201)  # H x4 from -6 to 6
a4_values = sp.lambdify(t, history, "numpy")(times)
a1_values = sp.lambdify(t, first, "numpy")(times)
a2_values = sp.lambdify(t, second, "numpy")(times)
```

1201 times from -6 to 6, 0.01 apart, and the values of a_4, a_4' and a_4'' at all of them.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0))
axes[0].semilogy(times, np.exp(a4_values), label="space, $e^{a_4}$ (inflates)")
axes[0].semilogy(times, np.exp(-a4_values), "--",
                 label="extra times, $e^{-a_4}$ (deflate)")
axes[0].set_xlabel("time $H x_4$")
axes[0].set_ylabel("scale factor (logarithmic scale)")
axes[0].set_title("scale factors of the test history")
axes[0].legend(fontsize=8)
```

The left panel: the scale factors e^{a_4} of 3-space and e^{-a_4} of the extra times (without the common factor $\sin^{1/6} z$) on a logarithmic axis, where exponential growth or decay is a straight line.

```
axes[1].plot(times, a1_values, label="$a_4^{\\prime}/H$")
axes[1].plot(times, a2_values, "--", label="$a_4^{\\prime\\prime}/H^2$")
axes[1].set_xlabel("time $H x_4$")
axes[1].set_ylabel("value")
axes[1].set_title("its first and second derivatives")
axes[1].legend(fontsize=8)
fig.tight_layout()
```

```
save_figure(fig, "test_history",
            "The illustrative test history $a_4 = H x_4 + \\frac{1}{2} \\ln\\cosh H "
            ...)
```

The right panel: a_4'/H and a_4''/H^2; then the figure is saved.

What Figure 11c.3 shows. Left: the solid line (e^{a_4}) rises and the dashed line (e^{-a_4}) falls at all times; both are straight on the logarithmic axis far from $x_4 = 0$, with the slope $\pm 1/2$ in the past and $\pm 3/2$ in the future, and they bend around $x_4 = 0$. Right: a_4'/H rises like a step from $1/2$ to $3/2$, and a_4''/H^2 is a bump of height $1/2$ at $x_4 = 0$. The history is an illustration, not a solution of any field equation.

In [9], the components along the test history (Figure 11c.4).

```
def along_history(expr):
    function = sp.lambdify((A1, A2), expr.subs(H, 1), "numpy")
    return np.broadcast_to(function(a1_values, a2_values), times.shape).astype(float)
```

`along_history` (docstring left out) evaluates an expression in a_4' and a_4'' (with $H = 1$) at all 1201 times at once.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.0))
middle = True
curves = {}
for ax, k in zip(axes, (1, 2, 3)):
    curves[k] = {h: along_history(E[k][h, h]) for h in (1, 4, 5, 0)}
    middle &= np.allclose(curves[k][0], (curves[k][1] + curves[k][5]) / 2,
                          rtol=1e-12, atol=1e-9)
```

For each order the four independent components are evaluated along the history and kept in `curves` (keys 0, 3, 4, 7 for x_1, x_4, x_5, x_0). The hidden component must equal the mean of the space and extra-time components at every time, up to rounding (`rtol` and `atol` are the allowed relative and absolute differences).

```
    for h, style in ((4, "-"), (1, "-"), (5, "--"), (0, ":")):
        ax.plot(times, curves[k][h], style,
                label=f"$E^{{x_{h}}}{{}}_{{x_{h}}}$")
    ax.set_xlabel("time $H x_4$")
    ax.set_ylabel(f"$E_{{({k})}}$ in units of $H^{{{2 * k}}}$")
    ax.set_title(f"order k = {k}")
    ax.legend(fontsize=7)
```

The four curves: time and space solid, extra times dashed, hidden dotted; the legend labels are built from the number `h + 1` of each coordinate.

```
fig.tight_layout()
save_figure(fig, "components_test_history",
            "The four independent components of $E_{(1)}$, $E_{(2)}$ and $E_{(3)}$ "
            ...)
check(middle, "along the test history E^x0_x0 is the mean of E^x1_x1 and E^x5_x5 "
              "at all 1201 times")
```

The figure is saved, and the check confirms identity (II) at all 1201 times. Fifteenth PASS line.

What Figure 11c.4 shows. In each panel the time component (blue) steps from one constant to another, for $k = 1$ from 21.75 to 27.75, because it depends on a_4' alone. The space (orange) and extra-time (dashed green) components step the other way and separate only near $x_4 = 0$, where $a_4'' \neq 0$: for $k = 1$ and $k = 3$ the space component lies above ($F_1, F_3 > 0$), for $k = 2$ below ($F_2 < 0$). The dotted hidden component runs exactly between them.

In [10], identity (I) numerically (Figure 11c.5).

```
step = times[1] - times[0]  # epsilon = 0.01
fig, axes = plt.subplots(1, 3, figsize=(12.0, 3.8))
worst = {}
for ax, k in zip(axes, (1, 2, 3)):
    left = np.gradient(curves[k][4], step)  # d/dx4 of the time component
    right = 3 * a1_values * (curves[k][1] - curves[k][5])
```

`step` is the spacing of the times, 0.01. `np.gradient(values, step)` estimates the derivative at every time by the central difference $(f(t+\epsilon) - f(t-\epsilon))/(2\epsilon)$ (at the two end points by a one-sided difference). `left` is the estimated derivative of the time component, `right` the right side of identity (I).

```
    inner = slice(1, -1)  # the two end points use a one-sided difference
    worst[k] = float(np.max(np.abs(left[inner] - right[inner]))
                     / np.max(np.abs(right)))
    report(f"order {k}: largest relative deviation of the finite difference",
           f"{worst[k]:.1e}")
```

`slice(1, -1)` leaves out the first and the last time, where the less accurate one-sided difference is used. The largest difference between the two sides, divided by the largest size of the right side, is the relative deviation; the RESULT lines print 3.8×10^{-5}, 4.0×10^{-5} and 4.5×10^{-5} (the format `:.1e`).

```
    ax.plot(times, right, color="tab:blue", lw=3, alpha=0.5,
            label="$3 a_4^{\\prime} (E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5})$")
    ax.plot(times, left, "k:", label="$d E^{x_4}{}_{x_4} / d x_4$ (finite difference)")
    ax.set_xlabel("time $H x_4$")
    ax.set_ylabel(f"units of $H^{{{2 * k + 1}}}$")
    ax.set_title(f"identity (I), order k = {k}")
    ax.legend(fontsize=7)
fig.tight_layout()
```

Both sides are drawn: the right side as a thick, half-transparent blue line (`lw=3`, `alpha=0.5`) and the finite difference as a dotted black line on top of it. One derivative with respect to x_4 adds one power of H, so the unit is H^{2k+1}.

```
largest = max(worst.values())  # the largest relative deviation of the three orders
power = int(np.floor(np.log10(largest)))  # its power of ten
deviation_text = f"${largest / 10 ** power:.1f} \\times 10^{{{power}}}$"
```

```
save_figure(fig, "conservation_identity",
            "Identity (I), the conservation identity along the time, checked "
            ...)
check(all(value < 1e-4 for value in worst.values()),
      "the finite-difference derivative agrees with identity (I) to 1e-4")
```

The largest deviation of the three orders is written into the caption in the form 4.5×10^{-5}: `np.log10` is the logarithm to the base 10, and `np.floor` rounds it down, which gives the power of ten. The check requires every relative deviation to be below 10^{-4}. Sixteenth PASS line.

What Figure 11c.5 shows. In each panel the dotted black line lies on the thick blue line: a bump at $x_4 = 0$, zero far away, where $a_4'' = 0$ and the time component is constant. The sign of the bump follows F_k (positive for $k = 1, 3$, negative for $k = 2$), times the positive $3a_4'a_4''$.

In [11], the quoted records once more.

```
def verdicts(path):
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    checks = data["checks"]
    if isinstance(checks, dict):  # name -> {"passed": true or false, ...}
        return {name: "PASS" if entry["passed"] else "FAIL"
                for name, entry in checks.items()}
    return {entry["name"]: entry["verdict"] for entry in checks}  # a list of entries
```

The helper of Notebook 11a, In [16] (Section 11.9): for one report, a dictionary from the name of each check to PASS or FAIL.

```
QUOTED = {  # report -> the checks that this notebook quotes from it
    "Revision/field_equations_a4/reports/python-a4-report.json": [
        "json_lovelock_components", "evolution_factorises", "bianchi_x4",
        "linear_member_vacuum_factor"],
    "Revision/gkd_lovelock/results/lovelock-report.json": [
        "k1_divergence_free", "k2_divergence_free", "k3_divergence_free"],
}
```

The checks quoted in the notebook, by report (here with the full paths, because the two reports lie in different folders).

```
for path, names in QUOTED.items():
    found = verdicts(path)
    for name in names:
        say(f"{path.split('/')[-1]}: {name} {found.get(name, 'MISSING')}")
    check(all(found.get(name) == "PASS" for name in names),
          f"the {len(names)} checks quoted from {path.split('/')[-1]} are there and "
          "PASS", record=f"{path}, checks " + ", ".join(names))
```

Each quoted check is printed with its verdict (`path.split('/')[-1]` is the file name, the last part of the path) and must be present with PASS. The notebook asks only for these names, not for the number of checks of the report, so it stays valid when the report gains checks. PASS lines seventeen and eighteen.

```
general = a4_record["generalSource"]  # a4-equations.json, read in section 5
stated = (general["algebraic_condition"]["input"] == "p3 + pt == 2*p0"
          and "rho' = -3 a4' (p3 - p_t)" in general["conservation_reduced"]
          and "p3 + p_t = 2 p0" in general["conservation_reduced"]
          and "d/dx4 (constraint) = 3 a4' (evolution)"
          in general["constraint_propagation"])
check(stated, "a4-equations.json states rho' = -3 a4' (p3 - p_t), p3 + p_t = 2 p0 and "
              "the constraint propagation, as quoted",
      record="Revision/field_equations_a4/a4-equations.json, generalSource: "
             "conservation_reduced, algebraic_condition, constraint_propagation")
```

The record of the field equations must state the three consequences quoted in Section 11.22: the algebraic condition $p_3 + p_t = 2p_0$ (in Wolfram's notation), the reduced conservation law $\rho' = -3a_4'(p_3 - p_t)$, and the constraint propagation. Nineteenth PASS line.

In [12], the end.

```
figure_files = [f"11c_{k}_{name}.png" for k, name in enumerate(
    ["components_linear_history", "lovelock_scalars", "test_history",
     "components_test_history", "conservation_identity"], 1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_files),
      "all five figure files of the notebook exist")
all_checks_passed()
```

The five figure files must exist (twentieth PASS line), and the last line is ALL 20 CHECKS PASSED (notebook 11c). The 20 checks are: 2 in In [2], 2 in In [3], 5 in In [4], 2 in In [5], 1 each in In [6] to In [10], 3 in In [11] and 1 in In [12].

11.28 What we proved, what we computed, what we assumed

PROVED in this chapter by derivations written out line by line (each confirmed by a check of a notebook and, where named, of a Revision record):

- **The generalized Kronecker delta** (Sections 11.3 and 11.4): the author's determinant $\det[\delta(l_i, u_j)]$ is 0 when a label repeats in either list or a lower label is missing above, and otherwise the sign of the permutation that carries the lower list into the upper list; so the rule GKD of the Revision program is exactly the author's definition (Notebook 11a, In [2] to In [6]; records `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, checks `gkd_equals_kdelta_exhaustive_length_1` to `_length_3`, which compare the Rust function GKD with the literal determinant, and `gkd-selftest.json`; the literal determinant itself is checked in `python-lovelock-report.json`, checks `gkd_examples` and `gkd_literal_equa ls_cofactor_expansion`, the second of which compares it with an independent cofactor expansion). The number of nonzero values $8!/(8-p)! \cdot p!$, half of them $+1$ and half -1 for $p \geq 2$, with the counts 8; 56 and 56; 1008 and 1008; 20160 and 20160 for $p = 1$ to 4 (In [6], In [7], In [9]; record `wolfram-gkd-report.json`, entry `gkdComparison`). Every delta with nine or more labels vanishes in eight dimensions (pigeonhole), so $P_{(4)} = 0$ and Lovelock's sum stops at order 3 (In [10]; record `lovelock-report.json`, check `k4_tensor_vanishes`). The rule needs $p(p-1)/2$ comparisons instead of the $p!$ products of the determinant. The birthday

probability $r_p = 8!/((8-p)!\,8^p)$ of a nonzero rearranged random pair (with the assumed rules of probability).

- **The author's second route** (Section 11.5): a determinant identity for the Levi-Civita symbol; raising all labels of the Levi-Civita tensor of a metric gives the factor $\sqrt{|\det g|}/\det g$, so the product of two Levi-Civita tensors is the sign of $\det g$ times the product of two symbols; for the author's metric $\det g = \cos^2 z > 0$ (record `python-lovelock-report.json`, check `sqrt_abs_det_g`), the sign is $+1$, and the author's second route gives the generalized delta without an extra sign.

- **The curvature that the sums use** (Section 11.10): the mixed components $R^{x_4 k}{}_{x_0 k} = \sigma_k H a_4' \cot z$ carry the sign $\sigma_k = \pm 1$ of inflation or deflation, not of the space-like or time-like character, and $R^{x_4}{}_{x_0} = 0$ because three inflating and three deflating directions cancel, on the background $b_4 = 1$ (with a changing b_4, $R^{x_4}{}_{x_0} = \frac{3}{2} H \cot z\, b_4'/b_4$, record `curvature.json`); every nonzero $R^{ab}{}_{cd}$ has the weight 2.

- **Laplace's rule** for determinants of every size, and **the expansion of every Lovelock tensor** along the column of its free upper label, $P_{(k)} = \delta\, L_{(k)} - 2k\, Y_{(k)}$ (Section 11.13; Notebook 11b, In [21]).

- **For every metric** (Sections 11.14 and 11.15): $L_{(1)} = 2R$, $P_{(1)} = -4G$, so $E_{(1)} = G$; the trace identity $\sum_h P_{(k)}{}^h{}_h = (8-2k) L_{(k)}$; $L_{(2)} = 4\,\mathrm{GB}$ and $P_{(2)} = -8\mathcal{H}$ with Lanczos's Gauss-Bonnet tensor $\mathcal{H}$, so $E_{(2)} = \mathcal{H}$ (Notebook 11b, In [18], In [19], In [22]; records `lovelock-report.json`, checks `k1_equals_minus_4_einstein`, `k1_trace_identity` to `k3_trace_identity`, and `python-lovelock-report.json`, checks `L1_equals_2R`, `k2_equals_minus_8_gauss_bonnet`, `L2_equals_4_gauss_bonnet`).

- **The structure of the components for the author's metric** (Section 11.21), for every history $a_4(x_4)$ and every order: only the diagonal is nonzero (in particular no x_4-x_0 component, by the relabelling that exchanges 3-space and the extra times), on the background $b_4 = 1$; with a changing b_4 the two mixed components are proportional to b_4'; the three space components are equal, and so are the three extra-time components; a_4'' enters at most linearly; the time component is a polynomial in $a_4'^2$ and H^2 alone (the constraint); the extra-time component is the space component with a_4'' replaced by $-a_4''$, so their difference is $a_4'' F_k(a_4')$ with $F_1 = 2$, $F_2 = -16(3a_4'^2 + 5H^2)$, $F_3 = 144(5a_4'^4 + 6a_4'^2 H^2 + 5H^4)$ (the evolution factor; record `Revision /field_equations_a4/reports/python-a4-report.json`, check `evolution_factorises`); the hidden component contains no a_4''; every component is even in a_4' (by reversing the time), so the tensors do not distinguish deflating from inflating extra times; order k has the weight $2k$; and $E^{x_4}{}_{x_4} - E^{x_0}{}_{x_0} = 6(a_4'^2 + H^2) V_k$ (record check `linear_member_vacuum_factor`). Notebook 11c, In [2] to In [5], confirms each statement with exact algebra.

- **The two conservation identities** (Section 11.22), from zero divergence: $\frac{d}{dx_4} E^{x_4}{}_{x_4} = 3a_4'(E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5})$ (I) and $E^{x_0}{}_{x_0} = \frac{1}{2}(E^{x_1}{}_{x_1} + E^{x_5}{}_{x_5})$ (II), and the constraint propagation $\partial E^{x_4}{}_{x_4}/\partial a_4' = 3a_4' F_k$ (record `python-a4-report.json`, check `bianchi_x4`; Notebook 11c, In [4] and In [5]).

- **Along the linear history** (Section 11.23): only two different components per order, even in the slope A; the scalars $L_{(1)}$ and $L_{(2)}$ vanish exactly at $A = \sqrt{7}$ and $A = \sqrt{2\sqrt{39} - 11}$; the derivatives of the illustrative test history.

PROVED by exact computation (no rounding; by the Revision's programs, recomputed by the notebooks):

- GKD equals the author's determinant for every one of the 266,304 pairs of lengths 1 to 3 (Notebook 11a, In [6]; the Wolfram report, checks `gkd_equals_kdelta_exhaustive_length_1` to `_length_3`, and the Rust self-test record `gkd-selftest.json`, whose exhaustive part also covers these lengths; on the same pairs the sympy report's check `gkd_literal_equals_cofactor_expansion` confirms the determinant side: the literal determinant equals an independent cofactor expansion) and for every one of the 16,777,216 pairs of length 4 (the Rust self-test of the record `gkd-selftest.json`, read and checked by Notebook 11a, In [14]; the run itself takes 7 to 13 minutes).
- The 25 nonzero Christoffel symbols, the 156 nonzero components $R^{ab}{}_{cd}$ and the Ricci scalar $R = 6a_4'^2 - 42H^2$ (Notebook 11b, In [6] to In [8]; records `curvature.json` and `python-lovelock-report.json`, check `rust_riemann_agrees`).
- All 3×64 components of $P_{(1)}, P_{(2)}, P_{(3)}$ and the scalars $L_{(1)}, L_{(2)}, L_{(3)}$, computed by the Rust program and again by the notebook's own GKD sum (Notebook 11b, In [3], In [4], In [14], In [15]; record `lovelock-tensors.json`, written again byte for byte; `python-lovelock-report.json`, checks `rust_k1_mixed_components_agree` to `rust_k3_mixed_components_agree` and `rust_L1_agrees` to `rust_L3_agrees`); the counters of the sums, 696, 32,640 and 495,360 GKD calls (In [14]; record `lovelock-report.json`, field `counters`); the literal sums of orders 1 and 2 without any skipping, with 10,140 and 1,581,840 GKD calls (In [16]; checks `k1_unpruned_literal_sum_agrees` and `k2_unpruned_literal_sum_agrees`); the cubic identity $L_{(3)} = 8(2T_1 + 8T_2 + \cdots + T_8)$ for the author's metric (In [20]; check `L3_equals_8_cubic_lovelock_density`); zero divergence and symmetry of all three tensors (record `lovelock-report.json`, checks `k1_divergence_free` to `k3_symmetric`); the 19 checks of the Rust program, the 49 of the sympy verification and the 29 of the Wolfram verification, none failed (In [3] and In [24]).
- The components $E_{(1)}, E_{(2)}, E_{(3)}$ of Section 11.20 equal those recorded for the field equations of a_4 (Notebook 11c, In [3]; `Revision/field_equations_a4/reports/python-a4-report.json`, check `json_lovelock_components`).

COMPUTED (numerical, with the measured accuracy):

- The Rust program's literal unpruned sums at a numerical point agree with the exact tensors to the relative rounding errors 1.40×10^{-15} ($k = 1$) and 4.41×10^{-14} ($k = 2$) (record `lovelock-report.json`, checks `k1_brute_force_numeric` and `k2_brute_force_numeric`; Notebook 11b, In [4], requires both below 10^{-10}).
- GKD equals the determinant on 12,000 pseudo-random pairs of lengths 4 to 9 (Notebook 11a, In [10]) and on 200,000 pairs of each length 5 to 9 (record `gkd-selftest.json`); the numbers of nonzero values lie within 1.6 standard deviations of the birthday expectation (In [11] and In [15]).
- The rule GKD is more than ten times faster than sympy's determinant for 200 pairs of length 7 (In [12]; the times themselves are not printed).
- The positive zero $A \approx 0.6010$ of $L_{(3)}$ on the linear history (Notebook 11c, In [7], 15 digits).

- Identity (I) along the illustrative test history by finite differences, to the relative deviations 3.8×10^{-5}, 4.0×10^{-5}, 4.5×10^{-5} for $k = 1, 2, 3$, the size of the finite-difference error (Notebook 11c, In [10]).

ASSUMED (used, not proved here):

- The author's metric, as given in the Revision record, and the curvature convention of Misner, Thorne and Wheeler (Chapter 3).
- Lovelock's theorem in general: for every metric the tensors $P_{(k)}$ are divergence-free and symmetric, and they are the only such tensors built from the metric and its first and second derivatives (D. Lovelock, J. Math. Phys. 12, 498 (1971)). For the author's metric divergence and symmetry are not assumed but PROVED by exact computation.
- The Chern-Gauss-Bonnet theorem (a classical result), quoted in Section 11.11 only to explain the name Euler density of $L_{(4)}$; nothing in this chapter depends on it, and $P_{(4)} = 0$ is proved there by the pigeonhole principle.
- The general formula of the cubic Lovelock density (a classical result): the record derived its coefficients from literal sums on random curvature tensors, and checked the identity exactly for the author's metric; we do not derive it by hand.
- The tensor rule for a change of coordinates (Section 3.14), used for the time reversal and the relabelling; the rules of determinants of Section 1.20 (rule 1 for matrices larger than 2×2 is a standard theorem); that two polynomials that agree for all values of their variables have the same coefficients; the rules of probability used for the random tests (independent chances multiply; the expectation and the standard deviation of a count).

HYPOTHESIS. None: this chapter is geometry of the given metric.

OPEN. Whether nature has the couplings α_2 and α_3 of the Gauss-Bonnet and the cubic tensor, and which sign of a_4' is realised, are not decided by the tensors computed here; Chapter 12 studies the field equations with the couplings as free parameters and shows that the sign of the deflation is set by the source and the initial data, not by gravity. The symmetry $A \to -A$ of this chapter is NOT the pairing of universes of masses $+m$ and $-m$ (Chapters 18 to 20); nothing in this chapter concerns the creation of universes or matter and antimatter.

11.29 Exercises

Exercise 1. Use the rule of Section 11.3 to compute (a) the delta with the lower list (x_1, x_2, x_3, x_4) and the upper list (x_3, x_1, x_4, x_2); (b) the delta with the lower list (x_5, x_1, x_2) and the upper list (x_1, x_2, x_5), and check (b) with the Leibniz formula; (c) the delta with the lower list (x_1, x_2, x_0) and the upper list (x_1, x_2, x_3).

Answer. (a) The places of x_1, x_2, x_3, x_4 in the upper list are 2, 4, 1, 3, so $\sigma = (2, 4, 1, 3)$. Its inversions are the pairs of entries $(2, 1)$, $(4, 1)$ and $(4, 3)$: three, an odd number, so the value is -1. (b) The places of x_5, x_1, x_2 in the upper list (x_1, x_2, x_5) are 3, 1, 2: $\sigma = (3, 1, 2)$ with the two inversions $(3, 1)$ and $(3, 2)$, so the value is $+1$. The matrix has the rows $(0, 0, 1)$ (x_5 is the third

upper label), $(1,0,0)$ and $(0,1,0)$; in the Leibniz formula only the permutation $\pi = (3,1,2)$ picks three ones, and its sign is $+1$, so $\det = +1$. (c) The lower label x_0 is not among the upper labels: row 3 is all zeros, case (c), and the value is 0.

Exercise 2. (a) How many of the 8^{10} pairs of index lists of length 5 have the value $+1$, how many -1, how many 0? (b) For the Rust self-test of length 6 (100,000 rearranged and 100,000 independent pairs), compute the expected number of nonzero values and its standard deviation, and compare with the record's count 7812.

Answer. (a) By the formula of Section 11.4,

$$N_{\neq 0}(5) = 8 \cdot 7 \cdot 6 \cdot 5 \cdot 4 \cdot 5! = 6720 \cdot 120 = 806400,$$

half of each sign: 403,200 values $+1$ and 403,200 values -1. The zeros are the rest:

$$8^{10} - 806400 = 1073741824 - 806400 = 1072935424.$$

(b) The two chances are

$$r_6 = \frac{8!}{2! \cdot 8^6} = \frac{20160}{262144} = 0.0769043, \qquad q_6 = \frac{N_{\neq 0}(6)}{8^{12}} = \frac{20160 \cdot 720}{68719476736} = 0.000211.$$

The expectation is $100000 \cdot (0.0769043 + 0.000211) = 7711.6$, and the standard deviation is

$$\begin{aligned} &\sqrt{100000 \cdot 0.0769043 \cdot 0.9230957 + 100000 \cdot 0.000211 \cdot 0.999789} \\ &\quad = \sqrt{7099.0 + 21.1} = \sqrt{7120.1} = 84.4. \end{aligned}$$

The record's 7812 lies $(7812 - 7711.6)/84.4 = 1.19$ standard deviations above the expectation, as Notebook 11a prints (In [15]).

Exercise 3. Compute the determinant of the matrix with the rows $(2,1,0)$, $(0,1,3)$, $(1,0,1)$ by Laplace's rule along its second column, and compare with the six-term formula, which gives 5.

Answer. The second column holds $M_{12} = 1$, $M_{22} = 1$, $M_{32} = 0$, with the signs $(-1)^{1+2} = -1$, $(-1)^{2+2} = +1$, $(-1)^{3+2} = -1$. The minor $M^{(12)}$ (row 1 and column 2 removed) has the rows $(0,3)$ and $(1,1)$, determinant $0 \cdot 1 - 3 \cdot 1 = -3$; the minor $M^{(22)}$ has the rows $(2,0)$ and $(1,1)$, determinant 2. So $\det M = -1 \cdot (-3) + 1 \cdot 2 - 0 = 3 + 2 = 5$, the same value.

Exercise 4. In a space of n dimensions, which orders k of the Lovelock tensors $P_{(k)}$ can be nonzero, for $n = 4, 5, 6, 8, 10$? Which scalars $L_{(k)}$ can be nonzero in eight dimensions?

Answer. The delta of $P_{(k)}$ has $2k + 1$ labels in each list, so $P_{(k)}$ vanishes when $2k + 1 > n$ (pigeonhole, Section 11.4). Hence: $n = 4$: $k = 1$ only (Einstein); $n = 5$ and $n = 6$: $k = 1, 2$; $n = 8$: $k = 1, 2, 3$; $n = 10$: $k = 1, 2, 3, 4$. For even $n = 2m$ the highest order is $m - 1$, as in the formula of Section 11.11. The scalar $L_{(k)}$ has $2k$ labels per list, so in eight dimensions $L_{(1)}$ to $L_{(4)}$ can be nonzero: $L_{(4)}$ is the Euler density, whose tensor $P_{(4)}$ vanishes; for the author's metric it is $-663552H^2a_4'^6 - 442368H^4a_4'^4 - 663552H^6a_4'^2$ (Notebook 11b, In [3]).

Exercise 5. On the author's history $a_4 = Hx_4$ ($A = 1$): (a) write the Einstein tensor and $P_{(1)}$; (b) check the trace identity of order 1 with $L_{(1)}$.

Answer. (a) With $a_4' = H$ and $a_4'' = 0$ the components of Section 11.20 give $G^{x_1}{}_{x_1} = -3 + 15 = 12$, $G^{x_4}{}_{x_4} = 3 + 21 = 24$, $G^{x_5}{}_{x_5} = 12$, $G^{x_0}{}_{x_0} = 15 - 3 = 12$ (in units of H^2), so

$$G = \mathrm{diag}(12, 12, 12, 24, 12, 12, 12, 12)\, H^2,$$
$$P_{(1)} = -4G = \mathrm{diag}(-48, -48, -48, -96, -48, -48, -48, -48)\, H^2.$$

(b) The trace is $\sum_h P_{(1)}{}^h{}_h = -4(7 \cdot 12 + 24)H^2 = -432H^2$. With $L_{(1)} = 12a_4'^2 - 84H^2 = -72H^2$, the identity gives $(8-2)L_{(1)} = 6 \cdot (-72)H^2 = -432H^2$: the same.

Exercise 6. On the same history $A = 1$: compute the four independent components of $E_{(2)}$, then $P_{(2)}$, $L_{(2)}$, and check the trace identity of order 2. What is special about the Gauss-Bonnet tensor on this history?

Answer. With $a_4' = H$, $a_4'' = 0$ (units of H^4): $E_{(2)}{}^{x_1}{}_{x_1} = 12 + 168 - 180 = 0$; $E_{(2)}{}^{x_4}{}_{x_4} = -36 - 120 - 420 = -576$; $E_{(2)}{}^{x_5}{}_{x_5} = 12 + 168 - 180 = 0$; $E_{(2)}{}^{x_0}{}_{x_0} = 12 + 168 - 180 = 0$. So $P_{(2)} = -8E_{(2)} = \mathrm{diag}(0, 0, 0, 4608, 0, 0, 0, 0)H^4$ and its trace is $4608H^4$. $L_{(2)} = -96 - 2112 + 3360 = 1152$ (units of H^4), and $(8-4)L_{(2)} = 4608$: the identity holds. On the author's history the Gauss-Bonnet tensor $E_{(2)}$ has only its time component; all seven other components vanish, because $12A^4 + 168A^2 - 180 = 12(A^2 - 1)(A^2 + 15)$ is zero at $A = 1$ (multiply out: $12(A^4 + 14A^2 - 15)$).

Exercise 7. Check identity (I) of Section 11.22 for $k = 3$ by hand, from the components of Section 11.20.

Answer. The time component $E_{(3)}{}^{x_4}{}_{x_4} = 360a_4'^6 + 648a_4'^4H^2 + 1080a_4'^2H^4 + 2520H^6$ depends on x_4 only through a_4', so its derivative is $\frac{d}{dx_4}E^{x_4}{}_{x_4} = (2160a_4'^5 + 2592a_4'^3H^2 + 2160a_4'H^4)\, a_4''$ (the chain rule; $6 \cdot 360 = 2160$, $4 \cdot 648 = 2592$, $2 \cdot 1080 = 2160$). The difference of the space and the extra-time component is $E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5} = 720a_4'^4a_4'' + 864a_4'^2a_4''H^2 + 720a_4''H^4$ (every term without a_4'' cancels, every term with a_4'' doubles). Then $3a_4'(E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5}) = (2160a_4'^5 + 2592a_4'^3H^2 + 2160a_4'H^4)a_4''$, which is the same. So (I) holds, and $F_3 = 720a_4'^4 + 864a_4'^2H^2 + 720H^4 = 144(5a_4'^4 + 6a_4'^2H^2 + 5H^4)$.

Exercise 8. Check identity (II) for $k = 3$, and explain without any computation why $E^{x_0}{}_{x_0}$ contains no $\cot z$ for every order.

Answer. $\frac{1}{2}(E^{x_1}{}_{x_1} + E^{x_5}{}_{x_5})$: the terms with a_4'' have opposite signs in the two components and cancel; the others are equal, so the mean is $-72a_4'^6 - 648a_4'^4H^2 - 1944a_4'^2H^4 + 360H^6$, which is $E_{(3)}{}^{x_0}{}_{x_0}$. Without computation: in $P^{x_0}{}_{x_0}$ the label x_0 already stands in both lists of the delta, so no curvature factor may carry x_0 (case a or b); every entry with $\cot z$ or $\tan z$ is a mixed entry and carries x_0 (Section 11.21, tool iii); so none occurs, and the factors are plane curvatures among $x_1, \ldots, x_7$, which contain no z.

Exercise 9. Show that $L_{(3)}$ has exactly one positive zero on the linear history, and locate it between two decimals.

Answer. With $u = A^2$ and $H = 1$, $L_{(3)} = 1152u^3 + 31104u^2 + 100224u - 40320 = 1152\, f(u)$ with $f(u) = u^3 + 27u^2 + 87u - 35$ (divide by 1152: $31104/1152 = 27$, $100224/1152 = 87$, $40320/1152 = 35$). For $u > 0$ the derivative $f'(u) = 3u^2 + 54u + 87$ is positive, so f increases; $f(0) = -35 < 0$ and $f(1) = 1 + 27 + 87 - 35 = 80 > 0$, so f has exactly one zero for $u > 0$, between 0 and 1. Further, $f(0.3612) = 0.04712 + 3.52257 + 31.42440 - 35 = -0.0059$ and $f(0.3613) = 0.04716 + 3.52452 + 31.43310 - 35 = +0.0048$, so the zero lies between $u = 0.3612$ and 0.3613, and $A = \sqrt{u}$ between $\sqrt{0.3612} \approx 0.60100$ and $\sqrt{0.3613} \approx 0.60108$, in agreement with $A = 0.6010$ of Notebook 11c (In [7]).

Exercise 10. (a) In two dimensions with the metric $g = \mathrm{diag}(1, -1)$ (one space-like, one time-like direction), compute $\varepsilon_{12}\varepsilon^{12}$ with the rule of Section 11.5. (b) The same with $g = \mathrm{diag}(-1, -1)$. (c) What decides the sign, and what is it for the author's metric?

Answer. (a) $|\det g| = 1$, so $\varepsilon_{12} = [12] = 1$, and $\varepsilon^{12} = g^{11}g^{22}\varepsilon_{12} = 1 \cdot (-1) \cdot 1 = -1$; the product is -1, the sign of $\det g = -1$. (b) $\varepsilon^{12} = (-1)(-1) \cdot 1 = +1$, the product is $+1$, the sign of $\det g = +1$. (c) The sign of $\det g$, which for a diagonal metric is (-1) to the number of negative entries: the number of time-like directions. The author's metric has four, $\det g = \cos^2 z > 0$, and the sign is $+1$.

Exercise 11. For the illustrative test history of Section 11.23, compute a_4' and a_4'' at $x_4 = 0$, and the four components of $E_{(1)}$ there. Check identity (II).

Answer. $a_4'(0) = H(1 + \frac{1}{2}\tanh 0) = H$ and $a_4''(0) = \frac{H^2}{2}\mathrm{sech}^2 0 = \frac{H^2}{2}$. Then (units of H^2): $E^{x_1}{}_{x_1} = -3+\frac{1}{2}+15 = 12.5$, $E^{x_4}{}_{x_4} = 3+21 = 24$, $E^{x_5}{}_{x_5} = -3-\frac{1}{2}+15 = 11.5$, $E^{x_0}{}_{x_0} = -3+15 = 12$. Identity (II): $\frac{1}{2}(12.5 + 11.5) = 12 = E^{x_0}{}_{x_0}$. The space and extra-time components differ by $a_4''F_1 = \frac{1}{2} \cdot 2 = 1$, as in Figure 11c.4 at $x_4 = 0$.

12 The field equations for a4: Einstein and Einstein-Lovelock

The author's metric contains exactly one unknown function, $a_4(x_4)$. This chapter derives, step by step, the equations that gravity imposes on that function: first by hand, as far as the algebra stays short, and then completely with four notebooks. We will find that the equations split into a constraint, an evolution equation, a hidden-direction equation and conditions on the matter; that no empty universe of this form exists; that the exponentially deflating history needs a source of a very unusual kind; that the equations do not care whether the extra times deflate or inflate; and that a condensate of the commuting field dirac16complex00 can be such a source exactly.

12.1 What this chapter does, and why

In Chapter 3 we met the author's metric: a rule that turns small steps $dx_0, \ldots, dx_7$ into squared lengths. Three of its directions, x_1, x_2, x_3, are ordinary 3-space; x_4 is the time; x_5, x_6, x_7 are the three **extra times**, which behave like time; x_0 is the **hidden** space direction. Lengths along 3-space are multiplied by e^{a_4} and lengths along the extra times by e^{-a_4}. When a_4 grows with the time x_4, 3-space inflates and the extra times **deflate exponentially**. That is the author's picture of the primordial universe.

A metric is not free. Einstein's great idea is that matter tells space how to curve: the curvature of the metric, collected into a tensor, equals a constant times the energy and momentum of the matter. The equations that say this are called the **field equations of gravity**. For the author's metric they become equations for the single function $a_4(x_4)$, and they answer questions such as:

- Can the author's metric exist with no matter at all? (No: Section 12.11.)
- If a_4 is given, what matter must be present? (The **required source**: Sections 12.8 to 12.12.)
- If the matter is given, how does a_4 evolve? (The evolution equation: Sections 12.9 and 12.21.)
- Do the equations prefer extra times that deflate? (No; deflation is a choice of sign: Section 12.12.)

- Can a field of this theory be the required source exactly, with the extra times deflating? (Yes, in three exact examples of the commuting field dirac16complex00, computed by this book: Section 12.26.)

We use the most general gravity theory that keeps the field equations of second order in eight dimensions, **Einstein-Lovelock gravity**, and its special case, Einstein gravity. Every formula comes from the Revision record (the folders `Revision/field_equations_a4`, `Revision/gkd_lovelock` and `Revision/lead_checks` of the repository) or from the book's own notebooks, which reproduce the record wherever the two overlap and say so in a PASS line. The four notebooks of the chapter are: Notebook 12a, which derives all the equations from the metric with exact computer algebra; Notebook 12b, which computes the source that the linear history $a_4 = AHx_4 + a_0$ requires; Notebook 12c, which integrates the evolution equation for prescribed sources; and Notebook 12d, which builds exact solutions of the coupled equations of gravity and of the field dirac16complex00, using the author's eight real 16 by 16 gamma matrices.

12.2 The words and symbols of this chapter

Each word below is defined in plain terms; the later sections make every definition precise with formulas.

- **Coordinates** $x_0, \ldots, x_7$: the eight numbers that name a point, in the author's order. x_1, x_2, x_3: ordinary 3-space. x_4: the time. x_5, x_6, x_7: the three extra times (time-like, they deflate exponentially). x_0: the hidden direction. In the Python code the positions 0 to 7 of a list stand for x_0 to x_7; so position 3 is the time x_4 and position 7 the hidden x_0.
- **Hidden angle** $z = 6Hx_0$: the metric depends on x_0 only through z, which runs from 0 to $\pi/2$ (the **patch**). $H > 0$ is a constant of the author's metric with the unit of an inverse length.
- **Prime**: $a_4' = da_4/dx_4$ and $a_4'' = d^2a_4/dx_4^2$. The code writes them as the symbols `ad1` and `ad2`.
- **Metric** $g_{\mu\nu}$: the table of numbers that turns coordinate steps into squared lengths, $ds^2 = \sum_{\mu,\nu} g_{\mu\nu}\, dx_\mu dx_\nu$. The author's metric is **diagonal**: only $g_{11}, g_{22}, \ldots, g_{00}$ are not zero. Its inverse $g^{\mu\nu}$ is then diagonal too, with $g^{\mu\mu} = 1/g_{\mu\mu}$.
- **Signature**: the signs of the diagonal entries, here $(+,+,+,+,-,-,-,-)$: four space-like and four time-like directions, written (4,4).
- **Scale factor**: the number by which lengths along a direction are multiplied; for a diagonal metric it is $\sqrt{|g_{\mu\mu}|}$.
- **Index up, index down**: a tensor is a table of numbers labelled by indices; an upper index and a lower index transform in opposite ways. $T^\mu{}_\nu$ has one of each and is called **mixed**. The diagonal metric moves an index up or down by multiplying by $g^{\mu\mu}$ or $g_{\mu\mu}$.
- **Sum convention**: in this chapter a sum is always written out with $\sum$ or said in words, except in the definitions of Section 12.7 and in the formulas quoted from the record, where an index that appears once up and once down is summed over its eight values; "no sum" marks the exceptions.

- **Christoffel symbol** $\Gamma^a{}_{bc}$: a combination of first derivatives of the metric that says how the coordinate directions turn from point to point.
- **Riemann tensor** $R^{ab}{}_{mn}$: the curvature, built from the Christoffel symbols and their derivatives. **Pair curvature** $K_{ab} = R^{ab}{}_{ab}$ (no sum): the curvature of the plane spanned by the directions a and b (a name used in this chapter).
- **Ricci tensor** $R^h{}_j$, **Ricci scalar** R, **Einstein tensor** $G^h{}_j$: sums of Riemann components defined in Section 12.6.
- **Generalized Kronecker delta** (GKD): a sign, $+1$, -1 or 0, attached to two lists of indices (Section 12.7). **Lovelock tensors** $E_{(1)}, E_{(2)}, E_{(3)}$: the three curvature tensors built with the GKD; $E_{(1)}$ is the Einstein tensor and $E_{(2)}$ the **Gauss-Bonnet** tensor.
- **Couplings**: $\alpha_1, \alpha_2, \alpha_3$ weigh the three Lovelock tensors; Λ is the **cosmological constant**; $\kappa > 0$ measures the strength of gravity. **Einstein gravity**: $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$. **Einstein-Gauss-Bonnet gravity**: $\alpha_1 = 1$, $\alpha_3 = 0$.
- **Energy-momentum tensor** $T^\mu{}_\nu$, also called the **source**: the energy and momentum of the matter. Its parts are the **energy density** $\rho = -T^{x_4}{}_{x_4}$, the **pressures** p_3 (3-space), p_t (extra times), p_0 (hidden direction), and the **mixed components** $q_{40} = T^{x_4}{}_{x_0}$ and $q_{04} = T^{x_0}{}_{x_4}$.
- **Anisotropic stress**: the difference $p_3 - p_t$ between the 3-space pressure and the extra-time pressure.
- **Equation of state** $w = p/\rho$: pressure divided by energy density.
- **Field equations**: the equations of gravity, $\sum_k \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda \delta^\mu_\nu = \kappa T^\mu{}_\nu$ (Section 12.8). Their four independent parts are the **constraint** (time, x_4), the 3-space equation, the extra-time equation and the **hidden equation** (x_0). The **evolution equation** is the 3-space equation minus the extra-time equation; the **algebraic condition** is $p_3 + p_t = 2p_0$.
- **Divergence** $\nabla_\mu T^\mu{}_\nu$: the curved-space form of "the change of a quantity in time plus its outflow"; zero divergence means **conservation**. The **Bianchi identity** says that the left-hand side of the field equations has zero divergence for every metric.
- **Vacuum**: no matter, $T^\mu{}_\nu = 0$.
- **Null vector**: a direction of zero length, such as the frame direction $x_4 + x_0$ (time-like plus space-like). The **null energy condition** along it is $\rho + p_0 \geq 0$; ordinary matter satisfies it. Matter with $\rho > 0$ and $w < -1$ violates it and is called **phantom**.
- **Linear member**: the history $a_4 = AHx_4 + a_0$ with a constant **slope** A. For $A > 0$ the extra times deflate as e^{-AHx_4}. The author's metric leaves $a_4(x_4)$ free, and the author requires only that the extra times deflate ($A > 0$); the **canonical history** $A = 1$ is the choice of the Revision record (ASSUMED, a prescribed background; Section 12.12).
- **Prescribed source**: a source chosen by hand to see what the equations do. It is ASSUMED, not derived from a field.
- **Condensate**: a solution of a field equation that depends on the time x_4 only.
- **Status labels**: PROVED (exact, with the verifier file and check name), COMPUTED (numerical, with its measured accuracy), ASSUMED, HYPOTHESIS, OPEN.

12.3 The author's metric, its determinant and the volume of seven directions

The author's metric is diagonal. With the abbreviation $s = \sin^{1/3} z$ and $z = 6Hx_0$ its eight diagonal entries are

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}s,\ e^{2a_4}s,\ e^{2a_4}s,\ -1,\ -e^{-2a_4}s,\ -e^{-2a_4}s,\ -e^{-2a_4}s\big),$$

in the order $x_0, \ldots, x_7$, on the background $b_4 = 1$ of the author's metric of 2026-10-14 (record check `metric_is_SPEC_section_1` of `Revision/field_equations_a4/reports/wolfram-a4-report.json`, which states the metric with b_4; Section 12.12 says what a changing b_4 changes). The scale factors are $\sqrt{|g_{11}|} = e^{a_4}\sin^{1/6} z$ for 3-space, $\sqrt{|g_{44}|} = 1$ for the time, $\sqrt{|g_{55}|} = e^{-a_4}\sin^{1/6} z$ for the extra times and $\sqrt{g_{00}} = \cot z$ for the hidden direction. When a_4 grows, the first grows and the third shrinks.

The **determinant** of the metric measures volume. We compute it line by line; after each line we name the rule that produced it.

$$\det g = g_{11}\, g_{22}\, g_{33}\, g_{44}\, g_{55}\, g_{66}\, g_{77}\, g_{00}$$

(the determinant of a diagonal matrix is the product of its diagonal entries)

$$= \big(e^{2a_4}s\big)^3 \cdot (-1) \cdot \big(-e^{-2a_4}s\big)^3 \cdot \cot^2 z$$

(the entries inserted; three equal factors written as a cube)

$$= (-1)\,(-1)^3\, e^{6a_4}\, e^{-6a_4}\, s^6\, \cot^2 z$$

(the power of a product is the product of the powers, $(xy)^3 = x^3y^3$, and $(e^u)^3 = e^{3u}$)

$$= s^6 \cot^2 z$$

($(-1)(-1)^3 = (-1)^4 = 1$ and $e^{6a_4}e^{-6a_4} = e^0 = 1$)

$$= \sin^2 z\, \cot^2 z = \cos^2 z$$

($s^6 = (\sin^{1/3} z)^6 = \sin^2 z$, and $\cot z = \cos z/\sin z$). On the patch $0 < z < \pi/2$ the cosine is positive, so

$$\sqrt{|\det g|} = \cos z.$$

This is PROVED (record `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `sqrt_abs_det_g_is_cos_z`; reproduced in Notebook 12a, In [4]). The function a_4 has dropped out. The reason is visible in the fourth line: the volume factor e^{3a_4} of the three inflating 3-space directions and the factor e^{-3a_4} of the three deflating extra times multiply to 1. The volume of the seven directions other than the time stays constant: what 3-space gains, the extra times lose.

12.4 The Christoffel symbols of the author's metric

Definition. For any metric the Christoffel symbols are

$$\Gamma^a{}_{bc} = \frac{1}{2}\sum_{d=1}^{8} g^{ad}(\partial_b g_{dc} + \partial_c g_{db} - \partial_d g_{bc}),$$

where ∂_b is the partial derivative with respect to the coordinate x_b. They are symmetric in the two lower indices, $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$, because exchanging b and c exchanges the first two terms in the bracket.

The formula for a diagonal metric. We simplify the definition for our metric, line by line.

$$\Gamma^a{}_{bc} = \frac{1}{2g_{aa}}(\partial_b g_{ac} + \partial_c g_{ab} - \partial_a g_{bc})$$

(the inverse metric is diagonal, so in the sum over d only $d = a$ survives, and $g^{aa} = 1/g_{aa}$; no sum over a)

$$\Gamma^a{}_{bc} = \frac{1}{2g_{aa}}(\delta_{ac}\,\partial_b g_{aa} + \delta_{ab}\,\partial_c g_{aa} - \delta_{bc}\,\partial_a g_{bb})$$

(an entry g_{ac} of a diagonal matrix is g_{aa} when $c = a$ and 0 otherwise; the Kronecker delta δ_{ac} is 1 when $a = c$ and 0 otherwise). This is the formula that Notebook 12a programs in In [5].

The derivatives of the metric. The metric depends on x_4 (through a_4) and on x_0 (through z) only; every other partial derivative is zero. By the chain rule $\partial_0 = (dz/dx_0)\,\partial_z = 6H\,\partial_z$. Then:

- $\partial_4 g_{11} = 2a_4'\,e^{2a_4}s = 2a_4'\,g_{11}$ (chain rule: the derivative of $e^{2a_4(x_4)}$ is $2a_4'e^{2a_4}$); the same for g_{22}, g_{33}.
- $\partial_4 g_{55} = -2a_4'\,g_{55}$ (the exponent is $-2a_4$); the same for g_{66}, g_{77}.
- $\partial_0 g_{11} = 6H\,e^{2a_4}\,\frac{1}{3}\sin^{-2/3} z\,\cos z = 2H\cot z\,g_{11}$ (power rule for $\sin^{1/3} z$, then $\sin^{-2/3} z\cos z = \sin^{1/3} z\cdot\cos z/\sin z$); likewise $\partial_0 g_{55} = 2H\cot z\,g_{55}$.
- $\partial_0 g_{00} = 6H\cdot 2\cot z\cdot(-1/\sin^2 z) = -12H\cot z/\sin^2 z$ (chain rule, with $d\cot z/dz = -1/\sin^2 z$).
- $g_{44} = -1$ is constant.

The symbols. Inserting these into the diagonal formula:

- $\Gamma^{x_1}{}_{x_1x_4} = \partial_4 g_{11}/(2g_{11}) = a_4'$ (the term with δ_{ac}, $a = c = x_1$, $b = x_4$).
- $\Gamma^{x_5}{}_{x_5x_4} = \partial_4 g_{55}/(2g_{55}) = -a_4'$: the same symbol with the opposite sign, because the extra times deflate where 3-space inflates.
- $\Gamma^{x_1}{}_{x_1x_0} = \Gamma^{x_5}{}_{x_5x_0} = 2H\cot z\,g_{11}/(2g_{11}) = H\cot z$ (sympy prints it as `H/tan(z)`).
- $\Gamma^{x_4}{}_{x_1x_1} = -\partial_4 g_{11}/(2g_{44}) = -2a_4'g_{11}/(-2) = a_4'\,e^{2a_4}\sin^{1/3} z$ (the term with δ_{bc}, $b = c = x_1$, $a = x_4$).

- $\Gamma^{x_4}{}_{x_5x_5} = -\partial_4 g_{55}/(2g_{44}) = -a_4'\, g_{55} = a_4'\, e^{-2a_4} \sin^{1/3} z$.
- $\Gamma^{x_0}{}_{x_1x_1} = -\partial_0 g_{11}/(2g_{00}) = -H \tan z \;\; g_{11} = -H e^{2a_4} \sin^{4/3} z/\cos z$ (using $\cot z/\cot^2 z = \tan z = \sin z/\cos z$).
- $\Gamma^{x_0}{}_{x_5x_5} = -H \tan z \; g_{55} = H e^{-2a_4} \sin^{4/3} z/\cos z$.
- $\Gamma^{x_0}{}_{x_0x_0} = \partial_0 g_{00}/(2g_{00}) = -6H/(\sin z \cos z) = -12H/\sin 2z$ (using $\sin 2z = 2\sin z \cos z$).

The same holds with x_1 replaced by x_2 or x_3 and x_5 by x_6 or x_7. **Counting**: for each of the six directions $i \in \{x_1, x_2, x_3, x_5, x_6, x_7\}$ there are $\Gamma^i{}_{ix_4}$, $\Gamma^i{}_{x_4i}$, $\Gamma^i{}_{ix_0}$, $\Gamma^i{}_{x_0i}$, $\Gamma^{x_4}{}_{ii}$ and $\Gamma^{x_0}{}_{ii}$: $6 \times 6 = 36$ symbols, plus $\Gamma^{x_0}{}_{x_0x_0}$: 37 nonzero symbols of the 512, of which 25 are different. Every other symbol is zero; for example $\Gamma^e{}_{x_4x_4} = 0$ for every e, because g_{44} is constant and no other entry has an index pair (x_4, x_4). This is PROVED by Notebook 12a (In [5], checks "37 nonzero Christoffel symbols (25 distinct, 12 of them twice)" and the symmetry check; In [6] prints the 25 distinct symbols; the record computes the same symbols in `Revision/field_equations_a4/wolfram/FieldEquationsA4.wl`).

12.5 The curvature computed by hand

Definition (the convention of Misner, Thorne and Wheeler, MTW).

$$R^a{}_{bmn} = \partial_m \Gamma^a{}_{bn} - \partial_n \Gamma^a{}_{bm} + \sum_e \Gamma^a{}_{me}\Gamma^e{}_{bn} - \sum_e \Gamma^a{}_{ne}\Gamma^e{}_{bm}, \qquad R^{ab}{}_{mn} = g^{bb}\, R^a{}_{bmn} \;\; \text{(no sum)}.$$

The tensor $R^{ab}{}_{mn}$ changes sign when a and b are exchanged, and when m and n are exchanged (record check `riemann_pair_antisymmetry`). So it is zero when $a = b$ or $m = n$, and the **pair curvature** $K_{ab} = R^{ab}{}_{ab}$ (no sum) is symmetric, $K_{ba} = R^{ba}{}_{ba} = (-1)(-1)R^{ab}{}_{ab} = K_{ab}$. The eight directions form $8 \cdot 7/2 = 28$ pairs. We compute four pair curvatures by hand.

The pair (3-space direction, time). Take $a = x_1$, $b = x_4$, $m = x_1$, $n = x_4$:

$$R^{x_1}{}_{x_4x_1x_4} = \partial_1 \Gamma^{x_1}{}_{x_4x_4} - \partial_4 \Gamma^{x_1}{}_{x_4x_1} + \sum_e \Gamma^{x_1}{}_{x_1e}\Gamma^e{}_{x_4x_4} - \sum_e \Gamma^{x_1}{}_{x_4e}\Gamma^e{}_{x_4x_1}$$

(the definition with these indices)

$$= 0 - a_4'' + 0 - a_4' \cdot a_4'$$

(nothing depends on x_1; $\Gamma^{x_1}{}_{x_4x_1} = a_4'$ has the derivative a_4''; every $\Gamma^e{}_{x_4x_4}$ is zero; in the last sum only $e = x_1$ survives, with $\Gamma^{x_1}{}_{x_4x_1} = a_4'$ twice)

$$R^{x_1x_4}{}_{x_1x_4} = g^{44}\, R^{x_1}{}_{x_4x_1x_4} = (-1)\big(-a_4'' - (a_4')^2\big) = (a_4')^2 + a_4''$$

(raise the index x_4 with $g^{44} = 1/g_{44} = -1$). The same steps with $\Gamma^{x_5}{}_{x_4x_5} = -a_4'$ give for an extra time and the time $K_{x_5x_4} = (a_4')^2 - a_4''$: the second derivative enters with the opposite sign.

The pair (3-space direction, hidden direction). With $a = m = x_1$ and $b = n = x_0$:

$$R^{x_1}{}_{x_0x_1x_0} = \partial_1\Gamma^{x_1}{}_{x_0x_0} - \partial_0\Gamma^{x_1}{}_{x_0x_1} + \sum_e \Gamma^{x_1}{}_{x_1e}\Gamma^{e}{}_{x_0x_0} - \sum_e \Gamma^{x_1}{}_{x_0e}\Gamma^{e}{}_{x_0x_1}$$

(the definition)

$$= 0 - 6H\frac{d}{dz}(H\cot z) + \Gamma^{x_1}{}_{x_1x_0}\Gamma^{x_0}{}_{x_0x_0} - \Gamma^{x_1}{}_{x_0x_1}\Gamma^{x_1}{}_{x_0x_1}$$

($\Gamma^{x_1}{}_{x_0x_0} = 0$; $\partial_0 = 6H\,d/dz$; of the $\Gamma^{e}{}_{x_0x_0}$ only $e = x_0$ is nonzero, and $\Gamma^{x_1}{}_{x_0e}$ is nonzero only for $e = x_1$)

$$= \frac{6H^2}{\sin^2 z} + H\cot z\cdot\Big(-\frac{6H}{\sin z\cos z}\Big) - H^2\cot^2 z$$

($d\cot z/dz = -1/\sin^2 z$, and the symbols of Section 12.4 inserted)

$$= \frac{6H^2}{\sin^2 z} - \frac{6H^2}{\sin^2 z} - H^2\cot^2 z = -H^2\cot^2 z$$

($\cot z/(\sin z\cos z) = 1/\sin^2 z$, because $\cot z = \cos z/\sin z$)

$$K_{x_1x_0} = g^{00}\,R^{x_1}{}_{x_0x_1x_0} = \frac{1}{\cot^2 z}(-H^2\cot^2 z) = -H^2$$

(raise x_0 with $g^{00} = 1/\cot^2 z$). The angle z has disappeared: the curvature of this plane is the same constant $-H^2$ everywhere.

Two 3-space directions. With $a = m = x_1$, $b = n = x_2$ the two derivative terms vanish ($\Gamma^{x_1}{}_{x_2x_2} = \Gamma^{x_1}{}_{x_2x_1} = 0$), and so does the last sum (every $\Gamma^{x_1}{}_{x_2e}$ is zero):

$$R^{x_1}{}_{x_2x_1x_2} = \Gamma^{x_1}{}_{x_1x_4}\Gamma^{x_4}{}_{x_2x_2} + \Gamma^{x_1}{}_{x_1x_0}\Gamma^{x_0}{}_{x_2x_2}$$

(the two values of e for which $\Gamma^{x_1}{}_{x_1e}$ is not zero)

$$= a_4'\cdot a_4'\,g_{22} + H\cot z\cdot(-H\tan z\,g_{22}) = \big((a_4')^2 - H^2\big)\,g_{22}$$

(the symbols of Section 12.4, and $\cot z\tan z = 1$), so $K_{x_1x_2} = g^{22}R^{x_1}{}_{x_2x_1x_2} = (a_4')^2 - H^2$.

A 3-space direction and an extra time. With $b = n = x_5$ the same two terms give $\Gamma^{x_1}{}_{x_1x_4}\Gamma^{x_4}{}_{x_5x_5} + \Gamma^{x_1}{}_{x_1x_0}\Gamma^{x_0}{}_{x_5x_5} = (a_4')^2e^{-2a_4}s + H^2e^{-2a_4}s$, and raising with $g^{55} = -e^{2a_4}/s$ gives $K_{x_1x_5} = -\big((a_4')^2 + H^2\big)$.

All 28 pairs. The computation of Notebook 12a (In [9]) confirms these values and gives the rest; the 28 pair curvatures fall into seven groups:

the pair	**number of pairs**	**pair curvature K**
two 3-space directions	3	$(a_4')^2 - H^2$

the pair	number of pairs	pair curvature K
two extra times	3	$(a_4')^2 - H^2$
a 3-space direction and an extra time	9	$-(a_4')^2 - H^2$
a 3-space direction and the time	3	$(a_4')^2 + a_4''$
an extra time and the time	3	$(a_4')^2 - a_4''$
any of the six above directions and x_0	6	$-H^2$
the time and x_0	1	0

Besides these 27 nonzero diagonal components there are 12 nonzero **off-diagonal** ones. They connect a pair that contains the time with the pair in which the time is replaced by x_0; for example

$$R^{x_1x_4}{}_{x_1x_0} = R^{x_4x_5}{}_{x_5x_0} = Ha_4' \cot z, \qquad R^{x_1x_0}{}_{x_1x_4} = R^{x_5x_0}{}_{x_4x_5} = -\frac{Ha_4'}{\cot z}.$$

Together: 39 nonzero components with $a < b$ and $m < n$, and $4 \times 39 = 156$ of the 4096 components $R^{ab}{}_{mn}$ (each one appears with its four orderings). Three facts follow: no component contains the warp factor $\sin^{1/3} z$ or e^{a_4}; every component is a polynomial in H, a_4', a_4'' and $\cot z$, divided at most by $\cot z$; and the antisymmetries hold. All three are PROVED. The sympy report of the record, `Revision/field_equations_a4/reports/python-a4-report.json`, has the checks `mixed_riemann_free_of_warp_and_a4`, `riemann_entries_laurent` and `riemann_pair_antisymmetry`; the Wolfram report has `mixed_riemann_free_of_warp_and_a4` (whose detail includes the Laurent form in $\cot z$) and `riemann_pair_antisymmetry`; and Notebook 12a reproduces them in In [8].

12.6 The Ricci tensor, the Ricci scalar and the Einstein tensor by hand

Definitions.

$$R^h{}_j = \sum_a R^{ah}{}_{aj}, \qquad R = \sum_h R^h{}_h, \qquad G^h{}_j = R^h{}_j - \tfrac{1}{2}\,\delta^h_j\, R.$$

A rule for the diagonal. For $h = j$ the definition gives $R^h{}_h = \sum_a R^{ah}{}_{ah} = \sum_{a \neq h} K_{ah}$: the sum of the pair curvatures of the seven pairs that contain h. Summing over h counts every pair twice (once from each of its two directions), so $R = 2 \sum_{\text{pairs}} K$. Therefore

$$G^h{}_h = \sum_{\text{pairs containing } h} K - \sum_{\text{all 28 pairs}} K = - \sum_{\text{pairs not containing } h} K,$$

(the definition of G with the two sums inserted; the pairs that contain h cancel). With the table of Section 12.5 everything follows by counting.

The Ricci scalar. Adding the seven groups, with their numbers of pairs:

$$\sum_{\text{pairs}} K = 3\big((a_4')^2 - H^2\big) + 3\big((a_4')^2 - H^2\big) - 9\big((a_4')^2 + H^2\big) + 3\big((a_4')^2 + a_4''\big) + 3\big((a_4')^2 - a_4''\big) - 6H^2 + 0$$

(the table, row by row)

$$= (3+3-9+3+3)(a_4')^2 + (-3-3-9-6)H^2 + (3-3)a_4'' = 3(a_4')^2 - 21H^2$$

(collect the terms with $(a_4')^2$, with H^2 and with a_4''), so $R = 6(a_4')^2 - 42H^2$, the RESULT line of Notebook 12a, In [11].

The time component. The pairs that do not contain x_4 are all rows of the table except the three rows with the time:

$$G^{x_4}{}_{x_4} = -\Big[3\big((a_4')^2 - H^2\big) + 3\big((a_4')^2 - H^2\big) - 9\big((a_4')^2 + H^2\big) - 6H^2\Big]$$

(the rule)

$$= -\big[\,-3(a_4')^2 - 21H^2\big] = 3(a_4')^2 + 21H^2$$

$(3+3-9 = -3$ and $-3-3-9-6 = -21)$.

The hidden component. The pairs without x_0 are the first five rows: $(3+3-9+3+3)(a_4')^2 + (-3-3-9)H^2 + (3-3)a_4'' = 3(a_4')^2 - 15H^2$, so $G^{x_0}{}_{x_0} = 15H^2 - 3(a_4')^2$.

The 3-space component. The pairs without x_1: one pair of two 3-space directions (x_2x_3), three of two extra times, six of a 3-space direction (x_2 or x_3) and an extra time, two of a 3-space direction and the time, three of an extra time and the time, five with x_0 (the six minus x_1x_0), and the time with x_0:

$$\sum = (1+3-6+2+3)(a_4')^2 + (-1-3-6-5)H^2 + (2-3)a_4'' = 3(a_4')^2 - 15H^2 - a_4'',$$

so $G^{x_1}{}_{x_1} = a_4'' - 3(a_4')^2 + 15H^2$.

The extra-time component. It uses the pairs without x_5: three pairs of two 3-space directions, one of two extra times (x_6x_7), six of a 3-space direction and an extra time (x_6 or x_7), three of a 3-space direction and the time, two of an extra time (x_6 or x_7) and the time, five with x_0 (the six minus x_5x_0), and the time with x_0:

$$\sum = (3+1-6+3+2)(a_4')^2 + (-3-1-6-5)H^2 + (3-2)a_4'' = 3(a_4')^2 - 15H^2 + a_4''$$

(the table, row by row, with the pair x_4x_0 contributing 0; collect the terms with $(a_4')^2$, with H^2 and with a_4''), so $G^{x_5}{}_{x_5} = -a_4'' - 3(a_4')^2 + 15H^2$.

These four components are PROVED (record `Revision/field_equations_a4/reports/python-a4-report.json` and the Wolfram report, check `einstein_components`; reproduced in Notebook 12a, In [12]).

Why the mixed component $G^{x_4}{}_{x_0}$ vanishes. For $h = x_4$, $j = x_0$ the sum $R^{x_4}{}_{x_0} = \sum_a R^{a x_4}{}_{a x_0}$ picks up the off-diagonal Riemann components. For a 3-space direction, $R^{x_1 x_4}{}_{x_1 x_0} = H a_4' \cot z$. For an extra time, $R^{x_5 x_4}{}_{x_5 x_0} = -R^{x_4 x_5}{}_{x_5 x_0} = -H a_4' \cot z$ (exchange of the upper pair). So

$$G^{x_4}{}_{x_0} = R^{x_4}{}_{x_0} = 3 H a_4' \cot z - 3 H a_4' \cot z = 0.$$

The three inflating 3-space directions and the three deflating extra times contribute equal and opposite amounts. The same happens for $G^{x_0}{}_{x_4}$, and every other off-diagonal component has no nonzero term at all. So the Einstein tensor is diagonal and does not depend on x_0 (PROVED: record `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, checks `einstein_off_diagonal_zero`, `einstein_isotropy`, `einstein_x0_independent`; reproduced in Notebook 12a, In [12]).

12.7 The Lovelock tensors: the Einstein tensor and its two companions

The generalized Kronecker delta. For two lists of n indices, $\delta^{h_1 \ldots h_n}_{j_1 \ldots j_n}$ is the determinant of the n by n matrix whose entry in row r and column c is the ordinary Kronecker delta $\delta^{h_r}_{j_c}$. Two equal upper indices give two equal rows and the determinant 0. Otherwise it is $+1$ if the lower list is an even rearrangement of the upper list (an even number of exchanges turns one into the other), -1 if it is an odd one, and 0 if the two lists do not hold the same indices (Chapter 1 and Chapter 11 prove this).

The Lovelock tensors (formula (4.38) of the book by Lovelock and Rund, as programmed in the record, with a sum over every repeated index):

$$P_{(k)}{}^{h}{}_{j} = \delta^{h\, h_1 \ldots h_{2k}}_{j\, j_1 \ldots j_{2k}}\; R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}, \qquad E_{(k)}{}^{h}{}_{j} = -\frac{P_{(k)}{}^{h}{}_{j}}{2^{k+1}}.$$

Only $k = 1, 2, 3$. For $k = 4$ the delta has $2k + 1 = 9$ upper indices taking only 8 values; two must be equal, so $P_{(4)} = 0$ (PROVED: Wolfram record, check `P4_vanishes_pigeonhole`; Notebook 12a, In [14]). In eight dimensions there are exactly three Lovelock tensors.

$E_{(1)}$ is the Einstein tensor. For $h = j$ the delta $\delta^{h\, h_1 h_2}_{h\, j_1 j_2}$ is not zero only when $h_1 \neq h_2$, both differ from h, and $\{j_1, j_2\} = \{h_1, h_2\}$. So only diagonal Riemann components enter:

$$P_{(1)}{}^{h}{}_{h} = \sum_{h_1 \neq h_2;\ h_1, h_2 \neq h} \left(\delta^{h\, h_1 h_2}_{h\, h_1 h_2} R^{h_1 h_2}{}_{h_1 h_2} + \delta^{h\, h_1 h_2}_{h\, h_2 h_1} R^{h_2 h_1}{}_{h_1 h_2} \right)$$

(the two possible orders of the lower indices)

$$= \sum_{h_1 \neq h_2;\ h_1, h_2 \neq h} \left(K_{h_1 h_2} + (-1)(-K_{h_1 h_2}) \right) = 4 \sum_{\text{pairs not containing } h} K$$

(one exchange gives the delta -1 and the Riemann component $-K$; each unordered pair appears twice as an ordered one). Hence $E_{(1)}{}^{h}{}_{h} = -P_{(1)}{}^{h}{}_{h}/4 = -\sum_{\text{pairs not containing } h} K = G^{h}{}_{h}$, the rule of Section 12.6. The record checks it in all 64 components (PROVED: Wolfram check `P1_direct_equals_minus_4_Einstein`, sympy check `P1_equals_minus_4_Einstein`; Notebook 12a, In [16]).

$E_{(2)}$ **and** $E_{(3)}$**.** For $k = 2, 3$ products of two or three Riemann components appear. Now the off-diagonal components also contribute: in a product such as $R^{x_1x_4}{}_{x_1x_0}\, R^{x_5x_0}{}_{x_4x_5}$ the factors $\cot z$ and $1/\cot z$ cancel. There are 690 contributing index lists for $k = 2$ and 4410 for $k = 3$ (Notebook 12a, In [15]); this bookkeeping is a job for the computer. The record's result, computed with the GKD in Rust (`Revision/gkd_lovelock/results/lovelock-tensors.json`), recomputed in Wolfram and in sympy, and reproduced by Notebook 12a in all 64 components of each tensor, is (record `Revision/field_equations_a4/a4-equations.json`, key `lovelockTensors`):

$$
\begin{aligned}
E_{(1)}{}^{x_1}{}_{x_1} &= -3(a_4')^2 + a_4'' + 15H^2, \qquad E_{(1)}{}^{x_4}{}_{x_4} = 3(a_4')^2 + 21H^2,\\
E_{(1)}{}^{x_5}{}_{x_5} &= -3(a_4')^2 - a_4'' + 15H^2, \qquad E_{(1)}{}^{x_0}{}_{x_0} = 15H^2 - 3(a_4')^2,\\
E_{(2)}{}^{x_1}{}_{x_1} &= 12(a_4')^4 - 24(a_4')^2 a_4'' + 168(a_4')^2H^2 - 40a_4''H^2 - 180H^4,\\
E_{(2)}{}^{x_4}{}_{x_4} &= -36(a_4')^4 - 120(a_4')^2H^2 - 420H^4,\\
E_{(2)}{}^{x_5}{}_{x_5} &= 12(a_4')^4 + 24(a_4')^2 a_4'' + 168(a_4')^2H^2 + 40a_4''H^2 - 180H^4,\\
E_{(2)}{}^{x_0}{}_{x_0} &= 12(a_4')^4 + 168(a_4')^2H^2 - 180H^4,
\end{aligned}
$$

$$
\begin{aligned}
E_{(3)}{}^{x_1}{}_{x_1} &= -72(a_4')^6 + 360(a_4')^4 a_4'' - 648(a_4')^4H^2 + 432(a_4')^2 a_4''H^2\\
&\quad - 1944(a_4')^2H^4 + 360a_4''H^4 + 360H^6,\\
E_{(3)}{}^{x_4}{}_{x_4} &= 360(a_4')^6 + 648(a_4')^4H^2 + 1080(a_4')^2H^4 + 2520H^6,\\
E_{(3)}{}^{x_5}{}_{x_5} &= -72(a_4')^6 - 360(a_4')^4 a_4'' - 648(a_4')^4H^2 - 432(a_4')^2 a_4''H^2\\
&\quad - 1944(a_4')^2H^4 - 360a_4''H^4 + 360H^6,\\
E_{(3)}{}^{x_0}{}_{x_0} &= -72(a_4')^6 - 648(a_4')^4H^2 - 1944(a_4')^2H^4 + 360H^6,
\end{aligned}
$$

with x_2, x_3 equal to x_1, x_6, x_7 equal to x_5, and every off-diagonal component zero. All of this is PROVED: the components computed from the curvature equal the Rust GKD record monomial by monomial (checks `P1_equals_gkd_branch_monomials` to `P3_equals_gkd_branch_monomials` of the sympy report and `P1_direct_equals_gkd_branch_monomials` to `P3_direct_equals_gkd_branch_monomials` of the Wolfram report); each $E_{(k)}$ is diagonal, free of x_0 and has zero divergence (checks `P1_structure` to `P3_structure` and `E1_divergence_free` to `E3_divergence_free` in both reports); and $E_{(2)}$ equals the classical Gauss-Bonnet tensor of Lanczos, which uses no GKD (Notebook 12a, In [18], for every a_4; for the linear member also record `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, checks `gauss_bonnet_rho_alpha2` and `gauss_bonnet_p_alpha2`). That every divergence-free tensor built from the metric and its first and second derivatives is a combination of these tensors is Lovelock's theorem (D. Lovelock, J. Math. Phys. 12, 498 (1971)), which this book quotes and does not prove.

12.8 The source and the independent field equations

The field equations of Einstein-Lovelock gravity are

$$
\sum_{k=1}^{3} \alpha_k\, E_{(k)}{}^{\mu}{}_{\nu} + \Lambda\, \delta^{\mu}_{\nu} = \kappa\, T^{\mu}{}_{\nu},
$$

64 equations, one for each pair (μ, ν). The left-hand side is built from the metric; the right-hand side is the source. We allow the most general source that the symmetry of the problem suggests:

$$T^{\mu}{}_{\nu} = \mathrm{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0) + q_{40}\ (\mu = x_4, \nu = x_0) + q_{04}\ (\mu = x_0, \nu = x_4).$$

The minus sign in $T^{x_4}{}_{x_4} = -\rho$ comes from $g^{44} = -1$: the energy density is the component T_{44} with both indices down, and raising the first index multiplies it by g^{44} (the convention of the record; the pressures are $p_\mu = T^{\mu}{}_{\mu}$, no sum).

Reduction. Three facts of Section 12.7 reduce the 64 equations.

1. Every off-diagonal left-hand side is zero. So the off-diagonal equations read $0 = \kappa T^{\mu}{}_{\nu}$: the source must have $q_{40} = q_{04} = 0$ and no other mixed component.
2. The left-hand sides of x_1, x_2, x_3 are equal, and so are those of x_5, x_6, x_7. So the source must have one pressure for 3-space and one for the extra times, as assumed.
3. No left-hand side depends on x_0. So no part of the source may depend on x_0.

What remains are four equations. With the abbreviations $e_{hh} = \sum_k \alpha_k E_{(k)}{}^{h}{}_{h}$ (no Λ; Notebook 12a calls them `e11`, `e44`, `e55`, `e00`):

$$\begin{aligned}
&\text{constraint } (x_4): && e_{44} + \Lambda = -\kappa\rho,\\
&\text{3-space } (x_1 = x_2 = x_3): && e_{11} + \Lambda = \kappa p_3,\\
&\text{extra times } (x_5 = x_6 = x_7): && e_{55} + \Lambda = \kappa p_t,\\
&\text{hidden } (x_0): && e_{00} + \Lambda = \kappa p_0.
\end{aligned}$$

This is PROVED (Wolfram record, check `independent_components`; sympy record, check `other_components_vanish`; reproduced in Notebook 12a, In [21]).

12.9 The constraint, the evolution equation and the algebraic condition

Einstein gravity first. With $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$ the four abbreviations are the Einstein components of Section 12.6:

$$e_{44} = 3(a_4')^2 + 21H^2, \quad e_{11} = a_4'' - 3(a_4')^2 + 15H^2, \quad e_{55} = -a_4'' - 3(a_4')^2 + 15H^2, \quad e_{00} = 15H^2 - 3(a_4')^2.$$

The time and hidden components contain a_4' but no a_4'': they are first-order equations. Subtracting the extra-time equation from the 3-space equation removes Λ:

$$e_{11} - e_{55} = \kappa(p_3 - p_t)$$

(3-space equation minus extra-time equation)

$$(a_4'' - 3(a_4')^2 + 15H^2) - (-a_4'' - 3(a_4')^2 + 15H^2) = \kappa(p_3 - p_t)$$

(the components inserted)

$$2a_4'' = \kappa(p_3 - p_t)$$

(the terms $-3(a_4')^2$ and $15H^2$ cancel). This is the **evolution equation**: the second derivative of a_4 is driven by the anisotropic stress, nothing else. Adding the two equations instead:

$$e_{11} + e_{55} = 30H^2 - 6(a_4')^2 = 2\,e_{00}$$

(the a_4'' cancel; $30H^2 - 6(a_4')^2 = 2(15H^2 - 3(a_4')^2)$), so the 3-space equation plus the extra-time equation minus twice the hidden equation reads $0 = \kappa(p_3 + p_t - 2p_0)$: the **algebraic condition** $p_3 + p_t = 2p_0$. It is not an equation for a_4 at all; it is a condition that every source must meet.

Einstein-Lovelock gravity. The same two combinations work for every coupling. From the components of Section 12.7, the Gauss-Bonnet part of $e_{11} - e_{55}$ is

$$E_{(2)}{}^{x_1}{}_{x_1} - E_{(2)}{}^{x_5}{}_{x_5} = -48(a_4')^2 a_4'' - 80H^2 a_4'' = a_4''(-48(a_4')^2 - 80H^2)$$

(the terms without a_4'' are equal in both and cancel; the others double), and the third-order part is $a_4''(720(a_4')^4 + 864(a_4')^2H^2 + 720H^4)$. So the evolution equation is

$$a_4''\,F(a_4') = \kappa(p_3 - p_t), \qquad F = 2\alpha_1 - \alpha_2(48(a_4')^2 + 80H^2) + \alpha_3(720(a_4')^4 + 864(a_4')^2H^2 + 720H^4),$$

and $e_{11}+e_{55} = 2e_{00}$ holds identically for each k (check for $k = 2$: $2\cdot12(a_4')^4+2\cdot168(a_4')^2H^2-2\cdot180H^4$ on both sides). All of this is PROVED; the checks are listed here:

Notebook 12a reproduces them in In [22] and In [23]. F vanishes for every a_4' and H only when all three couplings are zero. But for Einstein-Gauss-Bonnet gravity with $\alpha_2 > 0$, $F = 2 - 80\alpha_2H^2 - 48\alpha_2(a_4')^2$ is zero at $(a_4')^2 = (1 - 40\alpha_2H^2)/(24\alpha_2)$; there the evolution equation cannot be solved for a_4'' (figure 4 of Notebook 12a; Section 12.21).

What each equation does. Given a_4' at one time, the constraint fixes the energy density ρ at that time, and the hidden equation fixes p_0. Given the anisotropic stress, the evolution equation

fixes a_4'' and so the future of a_4. The algebraic condition then fixes p_3 and p_t from p_0 and the stress: $p_3 = p_0 + \frac{1}{2}(p_3 - p_t)$, $p_t = p_0 - \frac{1}{2}(p_3 - p_t)$.

12.10 The Bianchi identity and the conservation law

The identity. Each Lovelock tensor has zero divergence for every metric (PROVED for the author's metric with an arbitrary a_4: record checks `E1_divergence_free`, `E2_divergence_free`, `E3_divergence_free` in both reports; Notebook 12a, In [19]). Since $\Lambda\delta^\mu_\nu$ has zero divergence too, the field equations can hold only if the source has zero divergence.

The divergence of the general source. We compute it for the source of Section 12.8, whose parts $\rho, p_3, p_t, p_0, q_{40}, q_{04}$ may now depend on x_4 and x_0, from the definition of the covariant divergence (Section 9.9):

$$\nabla_\mu T^\mu{}_\nu = \sum_\mu \partial_\mu T^\mu{}_\nu + \sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda}\, T^\lambda{}_\nu - \sum_{\mu,\lambda} \Gamma^\lambda{}_{\mu\nu}\, T^\mu{}_\lambda .$$

Two sums of Christoffel symbols are needed first. From the list of Section 12.4:

$$\sum_\mu \Gamma^\mu{}_{\mu x_4} = 3a_4' + 3(-a_4') + 0 + 0 = 0$$

(the three 3-space directions give $\Gamma^{x_1}{}_{x_1 x_4} = a_4'$ each, the three extra times $\Gamma^{x_5}{}_{x_5 x_4} = -a_4'$ each, and $\Gamma^{x_4}{}_{x_4 x_4} = \Gamma^{x_0}{}_{x_0 x_4} = 0$), and

$$\sum_\mu \Gamma^\mu{}_{\mu x_0} = 6H\cot z - \frac{6H}{\sin z\cos z} = 6H\,\frac{\cos^2 z - 1}{\sin z\cos z} = -\frac{6H\sin z}{\cos z} = -6H\tan z$$

(the six directions $x_1, x_2, x_3, x_5, x_6, x_7$ give $H\cot z$ each, $\Gamma^{x_0}{}_{x_0 x_0} = -6H/(\sin z\cos z)$ and $\Gamma^{x_4}{}_{x_4 x_0} = 0$; then the common denominator $\sin z\cos z$, with $\cot z = \cos^2 z/(\sin z\cos z)$, and $\cos^2 z - 1 = -\sin^2 z$). This is $\partial_0 \ln\cos z = 6H\cdot(-\sin z/\cos z)$, the logarithmic derivative of $\sqrt{|\det g|} = \cos z$ (Section 12.3), as the lemma of Section 9.9 says.

The component $\nu = x_4$. The column $T^\lambda{}_{x_4}$ has only the entries $T^{x_4}{}_{x_4} = -\rho$ and $T^{x_0}{}_{x_4} = q_{04}$, and the entries $T^\mu{}_\lambda$ that are not zero are the eight diagonal ones and the two mixed ones $T^{x_4}{}_{x_0} = q_{40}$, $T^{x_0}{}_{x_4} = q_{04}$. So the three sums of the definition become

$$\nabla_\mu T^\mu{}_{x_4} = \partial_4 T^{x_4}{}_{x_4} + \partial_0 T^{x_0}{}_{x_4} + \Big(\sum_\mu \Gamma^\mu{}_{\mu x_4}\Big) T^{x_4}{}_{x_4} + \Big(\sum_\mu \Gamma^\mu{}_{\mu x_0}\Big) T^{x_0}{}_{x_4}$$
$$- \sum_\mu \Gamma^\mu{}_{\mu x_4} T^\mu{}_\mu - \Gamma^{x_0}{}_{x_4 x_4} T^{x_4}{}_{x_0} - \Gamma^{x_4}{}_{x_0 x_4} T^{x_0}{}_{x_4}$$

(the definition with $\nu = x_4$, keeping only the nonzero entries of T; in the next-to-last sum the diagonal entry $T^\mu{}_\mu$ has $\lambda = \mu$)

$$= -\partial_4\rho + \partial_0 q_{04} + 0 - 6H\tan z\, q_{04} - (3a_4'\, p_3 - 3a_4'\, p_t) - 0 - 0$$

(the entries inserted; the two sums of symbols above; on the diagonal $\Gamma^{x_1}{}_{x_1x_4} = a_4'$ multiplies p_3 three times and $\Gamma^{x_5}{}_{x_5x_4} = -a_4'$ multiplies p_t three times, while $\Gamma^{x_4}{}_{x_4x_4} = \Gamma^{x_0}{}_{x_0x_4} = 0$; and $\Gamma^{x_0}{}_{x_4x_4} = \Gamma^{x_4}{}_{x_0x_4} = 0$ by Section 12.4)

$$= -\partial_4\rho - 3a_4'(p_3 - p_t) + \partial_0 q_{04} - 6H\tan z\, q_{04}$$

(the terms reordered and $3a_4'$ taken out of the bracket).

The component $\nu = x_0$. In the same way, with the column $T^{x_4}{}_{x_0} = q_{40}$, $T^{x_0}{}_{x_0} = p_0$:

$$\nabla_\mu T^\mu{}_{x_0} = \partial_4 T^{x_4}{}_{x_0} + \partial_0 T^{x_0}{}_{x_0} + \Big(\sum_\mu \Gamma^\mu{}_{\mu x_4}\Big) T^{x_4}{}_{x_0} + \Big(\sum_\mu \Gamma^\mu{}_{\mu x_0}\Big) T^{x_0}{}_{x_0} - \sum_\mu \Gamma^\mu{}_{\mu x_0} T^\mu{}_\mu - \Gamma^{x_0}{}_{x_4x_0} T^{x_4}{}_{x_0} - \Gamma^{x_4}{}_{x_0x_0} T^{x_0}{}_{x_4}$$

(the definition with $\nu = x_0$, keeping only the nonzero entries of T)

$$= \partial_4 q_{40} + \partial_0 p_0 + 0 - 6H\tan z\, p_0 - \Big(3H\cot z\, p_3 + 3H\cot z\, p_t - \frac{6H}{\sin z\cos z}\, p_0\Big) - 0 - 0$$

(the entries inserted; on the diagonal the six directions give $H\cot z$ times their pressure, $\Gamma^{x_4}{}_{x_4x_0} = 0$, and $\Gamma^{x_0}{}_{x_0x_0} = -6H/(\sin z\cos z)$ multiplies p_0; $\Gamma^{x_0}{}_{x_4x_0} = 0$ because g_{00} does not depend on x_4, and $\Gamma^{x_4}{}_{x_0x_0} = -\partial_4 g_{00}/(2g_{44}) = 0$ for the same reason)

$$= \partial_0 p_0 + \Big(\frac{6H}{\sin z\cos z} - \frac{6H\sin z}{\cos z}\Big) p_0 - 3H\cot z\,(p_3 + p_t) + \partial_4 q_{40}$$

(the two terms with p_0 collected, $\tan z = \sin z/\cos z$)

$$= \partial_0 p_0 + 6H\cot z\, p_0 - 3H\cot z\,(p_3 + p_t) + \partial_4 q_{40}$$
$$= \partial_0 p_0 + 3H\cot z\,(2p_0 - p_3 - p_t) + \partial_4 q_{40}$$

($\frac{6H}{\sin z\cos z} - \frac{6H\sin^2 z}{\sin z\cos z} = 6H\,\frac{1-\sin^2 z}{\sin z\cos z} = 6H\,\frac{\cos z}{\sin z}$; then $3H\cot z$ taken out).

The six other components. For $\nu = x_1$ every term is zero: the column $T^\lambda{}_{x_1}$ has only $T^{x_1}{}_{x_1} = p_3$, which does not depend on x_1; $\sum_\mu \Gamma^\mu{}_{\mu x_1} = 0$, because no entry of the metric depends on x_1; and every symbol $\Gamma^\lambda{}_{\mu x_1}$ that multiplies a nonzero entry $T^\mu{}_\lambda$ is zero ($\Gamma^{x_1}{}_{x_1x_1} = 0$, and none of the nonzero symbols of Section 12.4 has exactly one index equal to x_1). The same holds for x_2, x_3, x_5, x_6, x_7.

These are the record's formulas (PROVED: record `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`, checks `divergence_x4_component`, `divergence_x0_component` and `divergence_other_components_zero`; Notebook 12a, In [25], which reproduces the first two of them and the sympy record's check `conservation_components`):

$$\nabla_\mu T^\mu{}_{x_4} = -\partial_4\rho - 3a_4'(p_3 - p_t) + \partial_0 q_{04} - 6H\tan z\, q_{04},$$
$$\nabla_\mu T^\mu{}_{x_0} = \partial_0 p_0 + 3H\cot z\,(2p_0 - p_3 - p_t) + \partial_4 q_{40},$$

and zero for the six other components. With the conditions of Section 12.8 (no x_0 dependence, $q_{40} = q_{04} = 0$) the first says $\rho' = -3a_4'(p_3 - p_t)$ and the second repeats the algebraic condition.

The constraint propagates. In Einstein gravity we can see directly why the constraint stays true along a solution:

$$-\kappa\rho = 3(a_4')^2 + 21H^2 + \Lambda$$

(the constraint)

$$-\kappa\rho' = 6a_4'a_4''$$

(differentiate with respect to x_4: chain rule for $(a_4')^2$; H and Λ are constants)

$$-\kappa\rho' = 3a_4' \cdot 2a_4'' = 3a_4'\,\kappa(p_3 - p_t)$$

(the evolution equation $2a_4'' = \kappa(p_3 - p_t)$ inserted)

$$\rho' = -3a_4'(p_3 - p_t)$$

(divided by $-\kappa$). So the constraint, differentiated, is $3a_4'$ times the evolution equation, exactly when the source obeys the conservation law. The record proves the same for every coupling, $\frac{d}{dx_4}e_{44} = 3a_4'(e_{11} - e_{55})$ (checks `constraint_propagation_bianchi` and `bianchi_x4`; Notebook 12a, In [23]). For the Gauss-Bonnet part, for example, $\frac{d}{dx_4}(-36(a_4')^4 - 120(a_4')^2H^2) = -144(a_4')^3a_4'' - 240a_4'a_4''H^2 = 3a_4' \cdot a_4''(-48(a_4')^2 - 80H^2)$.

What the conservation law means. The law $\rho' = -3a_4'(p_3 - p_t)$ is the first law of thermodynamics, $dE = -p\,dV$, for the two kinds of directions. The total volume of the seven directions other than the time is constant (Section 12.3), so the energy density can change only through the work of the pressures. The volume of 3-space grows like e^{3a_4}, so its logarithm grows at the rate $3a_4'$, and the pressure p_3 contributes $-3a_4'p_3$ per unit volume and time. The volume of the extra times shrinks like e^{-3a_4}, at the rate $-3a_4'$, and the pressure p_t contributes $+3a_4'p_t$. The total is $-3a_4'(p_3 - p_t)$: energy flows between 3-space and the extra times, and the energy density stays constant when the two pressures are equal. (This reading is an interpretation of the PROVED identity.)

12.11 Einstein gravity: no empty universe, and the null energy condition along x0

In Einstein gravity the constraint and the hidden equation read

$$3(a_4')^2 + 21H^2 + \Lambda = -\kappa\rho, \qquad -3(a_4')^2 + 15H^2 + \Lambda = \kappa p_0.$$

The null energy condition fails. Subtracting the first from the second:

$$(-3(a_4')^2 + 15H^2 + \Lambda) - (3(a_4')^2 + 21H^2 + \Lambda) = \kappa p_0 + \kappa\rho$$

(second equation minus first)

$$\kappa(\rho + p_0) = -6(a_4')^2 - 6H^2 = -6\big((a_4')^2 + H^2\big)$$

(Λ cancels; $15 - 21 = -6$). For $H > 0$ the right-hand side is negative for every a_4 and every Λ, so $\rho + p_0 < 0$ (with $\kappa > 0$). In the frame of the vielbein (the directions of unit length of Chapter 6) the energy-momentum tensor has $T_{\hat{4}\hat{4}} = \rho$ and $T_{\hat{8}\hat{8}} = p_0$, and the vector k with frame components $k^{\hat{4}} = k^{\hat{8}} = 1$ (all others 0) has zero length, $\eta(k,k) = -1 + 1 = 0$: a **null vector**. Then $T(k,k) = T_{\hat{4}\hat{4}} + 2T_{\hat{4}\hat{8}} + T_{\hat{8}\hat{8}} = \rho + 0 + p_0$. Every source of the author's metric in Einstein gravity violates the null energy condition along this null direction (PROVED: sympy and Wolfram records, check `einstein_null_energy_x0`; Notebook 12a, In [26]).

No vacuum. A vacuum needs $\rho = p_0 = 0$, so $6\big((a_4')^2 + H^2\big) = 0$, which no real a_4' satisfies when $H > 0$. If one allows complex numbers, the vacuum equations have exactly the two solutions $a_4' = \pm iH$, $\Lambda = -18H^2$ (from $(a_4')^2 = -H^2$ and $\Lambda = 3(a_4')^2 - 15H^2$), which are not real histories (PROVED: Wolfram record, check `einstein_no_vacuum_solution`; lead's record `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, check `no_vacuum_for_H_positive`; Notebook 12a, In [26] and figure 5). The author's metric is never empty space: it always needs matter, and that matter is of an unusual kind.

Every coupling. For Einstein-Lovelock gravity the same combination factorises: $\kappa(\rho + p_0) = -6\big((a_4')^2 + H^2\big)\,V$, with $V = \alpha_1 - 8\alpha_2\big((a_4')^2 + 5H^2\big) + \alpha_3\big(72(a_4')^4 + 144(a_4')^2H^2 + 360H^4\big)$ (PROVED by Notebook 12a, In [29], from the record's components). The null energy condition can hold only where $V \le 0$, and a vacuum needs $V = 0$. With the Einstein term at its usual weight, $\alpha_1 = 1$, this needs Lovelock couplings beyond Einstein's. The bracket $8\big((a_4')^2 + 5H^2\big)$ that multiplies $-\alpha_2$ and the bracket $72(a_4')^4 + 144(a_4')^2H^2 + 360H^4$ that multiplies α_3 are both positive, so $V \le 0$ needs a positive Gauss-Bonnet coupling α_2 or a negative third-order coupling α_3, large enough. For example, with $\alpha_3 = 0$:

$$V \le 0 \iff 1 \le 8\alpha_2\big((a_4')^2 + 5H^2\big) \iff \alpha_2 \ge \frac{1}{8\big((a_4')^2 + 5H^2\big)}$$

(the definition of V with $\alpha_1 = 1$ and $\alpha_3 = 0$; then division by the positive bracket). With $\alpha_2 = 0$, at a moment where $a_4' = 0$: $V = 1 + 360\alpha_3H^4 \le 0$ exactly when $\alpha_3H^4 \le -1/360$; for instance $\alpha_3H^4 = -1/300$ gives $V = 1 - 360/300 = -0.2$.

12.12 The linear member: the extra times deflate by a choice of sign

The history. The simplest history is $a_4 = AHx_4 + a_0$ with constants A and a_0. Then $a_4' = AH$ and $a_4'' = 0$, the 3-space scale factor grows like e^{AHx_4} and the extra-time scale factor shrinks like e^{-AHx_4}: for $A > 0$ the extra times deflate exponentially, at the rate AH. The author's metric does not fix the slope: the author requires only that the extra times deflate, $A > 0$. The Revision record takes $A = 1$ as its canonical history (ASSUMED, a prescribed background: the record `Revision/kohn_sham/results/parameters.json` writes "a4 = A H x4 (A = 1 canonical)" and calls it a PRESCRIBED BACKGROUND); this chapter calls $A = 1$ the **canonical history**.

The source it requires. Line by line:

- evolution equation with $a_4'' = 0$: $0 = \kappa(p_3 - p_t)$, so $p_3 = p_t$;
- algebraic condition: $p_3 + p_t = 2p_0$ with $p_3 = p_t$ gives $p_0 = p_3$; so all three pressures are equal, $p_3 = p_t = p_0 =: p$;
- constraint and hidden equation with $a_4' = AH$ give constant ρ and p.

In Einstein gravity:

$$\kappa\rho = -(21 + 3A^2)H^2 - \Lambda, \qquad \kappa p = (15 - 3A^2)H^2 + \Lambda, \qquad \kappa(\rho + p) = -6(1 + A^2)H^2.$$

For all three couplings the record's formulas are (PROVED: record checks `linear_member_equal_pressures` and `json_linear_member`; Notebook 12a, In [28], and Notebook 12b, In [3] to In [5]):

$$\begin{aligned}\kappa\rho &= \alpha_1(-3A^2 - 21)H^2 + \alpha_2(36A^4 + 120A^2 + 420)H^4 \\ &\quad + \alpha_3(-360A^6 - 648A^4 - 1080A^2 - 2520)H^6 - \Lambda, \\ \kappa p &= \alpha_1(15 - 3A^2)H^2 + \alpha_2(12A^4 + 168A^2 - 180)H^4 \\ &\quad + \alpha_3(-72A^6 - 648A^4 - 1944A^2 + 360)H^6 + \Lambda.\end{aligned}$$

Deflation is a choice of sign. The slope enters only as A^2, A^4 and A^6. Replacing A by $-A$ changes nothing: the equations accept extra times that deflate ($A > 0$) and extra times that inflate ($A < 0$) on exactly the same footing, and $A = 0$ (a static metric) as well. That the author's extra times deflate is a choice of sign, an initial condition; it is not a consequence of the field equations (PROVED: Notebook 12a, In [28], and Notebook 12b, In [4]; record key `theoremLinear` of `Revision/field_equations_a4/a4-equations.json`). This symmetry relates two histories of the metric of one universe. It is not the pairing of universes of masses $+m$ and $-m$, which is the subject of Chapters 18 to 20, and it says nothing about how a universe could be created.

The canonical history in numbers. For $A = 1$ and $\Lambda = 0$ (units $H = \kappa = 1$): $\kappa\rho = -24$, $\kappa p = 12$, $w = p/\rho = -1/2$ (Notebook 12b, In [5]). The energy density is negative. A positive energy density needs $-(21 + 3A^2)H^2 - \Lambda > 0$, that is $\Lambda < -(21 + 3A^2)H^2$, and then:

$$\kappa(\rho + p) = -6(1 + A^2)H^2 < 0 \;\Rightarrow\; p < -\rho \;\Rightarrow\; \frac{p}{\rho} < -1$$

(the sum of the two formulas; then divide by $\rho > 0$, which keeps the direction of the inequality). A positive energy density comes only with $w < -1$: the source is phantom (PROVED: Notebook 12b, In [8], checks for $\Lambda = -30H^2$, $-40H^2$, $-60H^2$ and the identity $w + 1 = (\rho + p)/\rho$).

The Gauss-Bonnet vacuum. With $\alpha_1 = 1$, $\alpha_3 = 0$ the record factorises $\kappa(\rho+p) = -6(A^2+1)H^2\,V$ with $V = 1 - 8\alpha_2 H^2(A^2 + 5)$ (record checks `linear_member_vacuum_factor`, `einstein_gauss_bonnet_vacuum_linear`). A vacuum needs $V = 0$, that is

$$A^2 = \frac{1 - 40\alpha_2 H^2}{8\alpha_2 H^2},$$

a real slope only for $0 < \alpha_2 H^2 \le 1/40$, and then the Λ that makes $\rho = 0$ (Notebook 12b, In [10] and In [11], figures 5 and 6). At the edge $\alpha_2 H^2 = 1/40$ the vacuum is static, $A = 0$, with $\Lambda = -21H^2 + 420H^2/40 = -10.5H^2$. With the third-order coupling the vacuum condition is, for each A, a straight line in the plane of $\alpha_2 H^2$ and $\alpha_3 H^4$ (Notebook 12b, In [12], figure 7). Whether nature has such couplings is not known; the Revision record makes no claim about their values.

The metric with b_4: what changes in the field equations. On 2026-10-14 the author gave the extra-time entries of the metric a second function $b_4(x_4) > 0$: $g_{x_5x_5} = g_{x_6x_6} = g_{x_7x_7} = -e^{-2a_4} b_4 \sin^{1/3} z$ (Chapter 3). Every derivation of Sections 12.3 to 12.12, and the four notebooks of this chapter, are made on the background $b_4 = 1$; the keys `lovelockTensors` to `fields` of `Revision/field_equations_a4/a4-equations.json` hold this case. The record's key `b4` holds the same equations for a general b_4 (the Wolfram verifier `Revision/field_equations_a4/wolfram/verify_field_equations_a4.wls`, whose report `wolfram-a4-report.json` treats the metric with b_4, and the sympy twin `Revision/field_equations_a4/python/check_b4_block.py` with the report `python-b4-block.json`, 11 of 11; `Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`). This section states what changes; it quotes the record, with the symbols $u = b_4'/b_4$.

The Einstein tensor gets two mixed components. For example (key `b4/lovelockTensors/E1`)

$$G^{x_4}{}_{x_0} = \frac{3}{2} H \cot z \, \frac{b_4'}{b_4}, \qquad G^{x_0}{}_{x_4} = -\frac{3}{2} H \tan z \, \frac{b_4'}{b_4},$$

and the diagonal components gain terms in b_4'/b_4 and b_4''/b_4; at $b_4 = 1$ they are those of Section 12.6. So "every off-diagonal left-hand side is zero" (Section 12.8) holds only for a constant b_4.

A changing b_4 needs a mixed source. The mixed equations read $\kappa q_{40} = \cot z \, (b_4'/b_4) \, Q$ and $\kappa q_{04} = -\tan z \, (b_4'/b_4) \, Q$ with a polynomial Q in H, a_4' and u (key `b4/generalSource/offDiagonalFactor_Q`); for Einstein gravity $Q = \frac{3}{2} H$. A source with $q_{40} = q_{04} = 0$, in particular every source that does not depend on x_0 and has no $T^{x_4}{}_{x_0}$, therefore forces $b_4' Q = 0$, and for Einstein gravity $b_4' = 0$ (key `b4/generalSource/offDiagonalStatement`).

The algebraic condition gains a b_4 term. For Einstein gravity $\kappa \, (p_3 + p_t - 2p_0) = \frac{1}{4}(b_4'/b_4)^2 + \frac{b_4''}{2b_4}$ (key `b4/generalSource/identity_einstein`); with $b_4' = b_4'' = 0$ it is the condition $p_3 + p_t = 2p_0$ of Section 12.9.

The conservation law gains the ordinary term of the extra times. The x_4 component becomes $\partial_4 \rho = -3a_4'(p_3 - p_t) - \frac{3}{2}\frac{b_4'}{b_4}(p_t + \rho) + \dots$ (the dots are the terms with q_{04}; key `b4/generalSource/conservation_x4`; Section 9.10).

Two second-order equations and a constraint. The $x_1 - x_5$ and x_0 components are linear in (a_4'', b_4'') with a nonsingular Jacobian, so they determine a_4'' and b_4'' from the source; the x_4 component is the constraint (key `b4/generalSource/secondOrderEinstein`).

The vacuum. With the author's weights ($w_1 = 1$, $w_2 = 1/32$, $w_3 = 1/1152$, $\Lambda = 10$) every vacuum solution has a constant b_4 and $a_4 = \pm H x_4 +$ const (`Revision/metric_b4/results/vacuum-b4.json`, 6 of 6 checks); the background $b_4 = 1$ of this chapter is of this kind.

The condensate. For a changing b_4 the gravitational term is $3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ (Chapter 6); the condensate of Section 12.26 becomes $\Phi = b_4^{-3/4} \Phi_1$ with a solution Φ_1 of the case $b_4 = 1$, and $b_4^{3/2} S$ is constant (key `b4/fields/condensate`).

Status: these statements are PROVED in the record (`python-b4-block.json` and `wolfram-a4-report.json`); this book quotes them and does not derive them.

12.13 Example: the field equations derived by computer algebra

The first notebook repeats everything of Sections 12.3 to 12.12 with exact computer algebra, starting from nothing but the metric, and compares every result with the Revision record. It computes the 37 Christoffel symbols, the 156 nonzero Riemann components, the Einstein tensor and the three Lovelock tensors (with its own GKD), checks them against the Rust program of the GKD record in all 64 components and against the classical Gauss-Bonnet formula, writes and reduces the field equations, checks the Bianchi identity and the conservation law, and specialises to Einstein gravity and to the linear member. It runs in about 20 seconds, prints 59 PASS lines and draws five figures. It needs no Rust.

12.14 How to run Notebook 12a

Step 1. What this notebook does and what it needs.

Notebook 12a (The field equations for a4 derived with sympy) is the file `Revision/textbook/notebooks/12a_a4_field_equations.ipynb` of the repository Dirac_claude. It derives with sympy, from the metric of the author, the Christoffel symbols, the Riemann, Ricci and Einstein tensors and the three Lovelock tensors (with the generalized Kronecker delta), writes the Einstein-Lovelock field equations for a4, reduces them to the constraint, the evolution equation, the hidden equation and the conditions on the source, checks the Bianchi identity, the conservation law of the source, the Einstein case (no vacuum, the null energy condition along x0) and the linear member a4 = A H x4, compares every result with the Revision records, and draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
```

```
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 12a_a4_field_equations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12a_a4_field_equations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 12a_a4_field_equations.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/12a.captions.json`
- `Revision/textbook/figures/12a_1_riemann_matrix.png`
- `Revision/textbook/figures/12a_2_einstein_components.png`
- `Revision/textbook/figures/12a_3_lovelock_heat_maps.png`
- `Revision/textbook/figures/12a_4_evolution_factor.png`
- `Revision/textbook/figures/12a_5_no_vacuum_gap.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files exist
ALL 59 CHECKS PASSED (notebook 12a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/12a_a4_field_equations.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 12a_a4_field_equations.ipynb
python -m nbconvert --execute --inplace 12a_a4_field_equations.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The cell of section 10, which computes the three Lovelock tensors, runs for a minute or more: it adds about five thousand products of curvature components in pure Python, which takes a few seconds on a fast computer and can take a few minutes on a slow one. The cell is not stuck: wait until the PASS lines appear below it.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads the Revision records of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

12.15 Notebook 12a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/12a_a4_field_equations.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook derives, step by step and with exact algebra (no rounding anywhere),
the field equations of gravity for the one unknown function $a_4(x_4)$ of the
author's metric. Starting from nothing but the metric, it

- writes the metric of the author in the computer-algebra package sympy and checks
  its signature and its determinant;
- computes the Christoffel symbols, the Riemann curvature tensor, the Ricci tensor,
  the Ricci scalar and the Einstein tensor;
- computes the three Lovelock tensors $E_{(1)}, E_{(2)}, E_{(3)}$ with the
  generalized Kronecker delta (the first one is the Einstein tensor, the second one
  the Gauss-Bonnet tensor), and checks the second one against the classical
  Gauss-Bonnet formula;
- writes the Einstein-Lovelock field equations with a general source and reduces
  them to a constraint, an evolution equation, a hidden-direction equation and the
```

  conditions every source must satisfy;
- checks the Bianchi identity and the conservation law of the source;
- specialises to Einstein gravity: no vacuum solution exists for $H > 0$, and every
  source violates the null energy condition along x_0;
- specialises to the linear member $a_4 = A H x_4 + a_0$ (exponentially deflating
  extra times for $A > 0$) and shows that the equations do not see the sign of A;
- compares every result with the Revision records and draws five teaching plots.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 12a (The field equations for a4 derived with sympy) is the file
‘Revision/textbook/notebooks/12a_a4_field_equations.ipynb‘ of the repository
Dirac_claude. It derives with sympy, from the metric of the author, the Christoffel
symbols, the Riemann, Ricci and Einstein tensors and the three Lovelock tensors (with the
generalized Kronecker delta), writes the Einstein-Lovelock field equations for a4,
reduces them to the constraint, the evolution equation, the hidden equation and the
conditions on the source, checks the Bianchi identity, the conservation law of the
source, the Einstein case (no vacuum, the null energy condition along x0) and the linear
member a4 = A H x4, compares every result with the Revision records, and draws five
teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:
```

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in

this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 12a_a4_field_equations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the

address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12a_a4_field_equations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 12a_a4_field_equations.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/12a.captions.json‘
- ‘Revision/textbook/figures/12a_1_riemann_matrix.png‘
- ‘Revision/textbook/figures/12a_2_einstein_components.png‘
- ‘Revision/textbook/figures/12a_3_lovelock_heat_maps.png‘
- ‘Revision/textbook/figures/12a_4_evolution_factor.png‘
- ‘Revision/textbook/figures/12a_5_no_vacuum_gap.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files exist
ALL 59 CHECKS PASSED (notebook 12a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/12a_a4_field_equations.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 12a_a4_field_equations.ipynb
      python -m nbconvert --execute --inplace 12a_a4_field_equations.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The cell of section 10, which computes the three Lovelock tensors, runs for a minute or more: it adds about five thousand products of curvature components in pure Python, which takes a few seconds on a fast computer and can take a few minutes on a slow one. The cell is not stuck: wait until the PASS lines appear below it.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads the Revision records of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a

check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 12a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 12a (The field equations for a4 derived with sympy) is the file
# Revision/textbook/notebooks/12a_a4_field_equations.ipynb of the repository
# Dirac_claude. It derives with sympy, from the metric of the author, the Christoffel
# symbols, the Riemann, Ricci and Einstein tensors and the three Lovelock tensors (with
# the generalized Kronecker delta), writes the Einstein-Lovelock field equations for a4,
# reduces them to the constraint, the evolution equation, the hidden equation and the
# conditions on the source, checks the Bianchi identity, the conservation law of the
# source, the Einstein case (no vacuum, the null energy condition along x0) and the
# linear member a4 = A H x4, compares every result with the Revision records, and draws
# five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
# shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
```

```
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 12a_a4_field_equations.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
```

```
#     jupyter nbconvert --to notebook --execute --inplace 12a_a4_field_equations.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 12a_a4_field_equations.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/12a.captions.json
# - Revision/textbook/figures/12a_1_riemann_matrix.png
# - Revision/textbook/figures/12a_2_einstein_components.png
# - Revision/textbook/figures/12a_3_lovelock_heat_maps.png
# - Revision/textbook/figures/12a_4_evolution_factor.png
# - Revision/textbook/figures/12a_5_no_vacuum_gap.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files exist
#     ALL 59 CHECKS PASSED (notebook 12a)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/12a_a4_field_equations.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
```

```
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 12a_a4_field_equations.ipynb
#     python -m nbconvert --execute --inplace 12a_a4_field_equations.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - The cell of section 10, which computes the three Lovelock tensors, runs for a minute
#   or more: it adds about five thousand products of curvature components in pure Python,
#   which takes a few seconds on a fast computer and can take a few minutes on a slow
#   one. The cell is not stuck: wait until the PASS lines appear below it.
# - "FileNotFoundError" naming a file below the folder Revision: the notebook reads the
#   Revision records of the repository. Run it inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository made with git clone,
#   not on a copy of the notebook file alone.
#
# ------------------------------------------------------------------------------------

Text cell:

```
## 3. The words used in this notebook
```

- **Coordinates** $x_0, \dots, x_7$ (the author's names): x_1, x_2, x_3 are ordinary 3-space; x_4 is the time; x_5, x_6, x_7 are the three **extra times** (time-like directions); x_0 is the **hidden** space direction. In the code the positions 0 to 7 of a list stand for x_0 to x_7.
- **Metric** $g_{\mu\nu}$: the table of numbers that turns small coordinate steps into squared lengths. Here it is **diagonal**: only $g_{11}, \dots, g_{00}$ are not zero.
- **Scale factor**: the factor by which a length along a direction grows. 3-space has $e^{a_4}\sin^{1/6} z$, the extra times have $e^{-a_4}\sin^{1/6} z$.
- **Deflating**: shrinking. When a_4 grows, e^{-a_4} shrinks: the extra times deflate exponentially while 3-space inflates.
- **Christoffel symbol** $\Gamma^a{}_{bc}$: the combination of first derivatives of the metric that tells how the coordinate directions turn from point to point.
- **Riemann tensor** $R^{ab}{}_{cd}$: the curvature; built from the Christoffel symbols and their derivatives. **Ricci tensor** $R^h{}_j = R^{ah}{}_{aj}$ (sum over a), **Ricci scalar** $R = R^h{}_h$, **Einstein tensor** $G^h{}_j = R^h{}_j - \tfrac12 \delta^h_j R$.
- **Generalized Kronecker delta** (GKD) $\delta^{h_1 \dots h_n}_{j_1 \dots j_n}$: $+1$ when the lower list is an even rearrangement of the upper list, -1 when it is an odd rearrangement, 0 otherwise (also when an index repeats).
- **Lovelock tensor** $E_{(k)}$: a tensor built from k factors of the Riemann tensor with the GKD; $E_{(1)}$ is the Einstein tensor, $E_{(2)}$ the Gauss-Bonnet tensor. In 8 dimensions only $k = 1, 2, 3$ exist.
- **Source**, **energy-momentum tensor** $T^\mu{}_\nu$: the matter that bends the metric. Its parts: the energy density $\rho = -T^{x_4}{}_{x_4}$, the pressures p_3 (3-space), p_t (extra times), p_0 (hidden direction), and the mixed components $q_{40} = T^{x_4}{}_{x_0}$, $q_{04} = T^{x_0}{}_{x_4}$.
- **Couplings**: $\alpha_1, \alpha_2, \alpha_3$ (the weights of the three Lovelock tensors), Λ (the cosmological constant), κ (the strength of gravity). **Einstein gravity** is $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$.
- **Constraint**: an equation with no second derivative a_4''. **Evolution equation**: the equation that contains a_4''.
- **Bianchi identity**: the left-hand side of the field equations has zero divergence for every metric; **conservation**: the source must then have zero divergence too.
- **Vacuum**: no source, $T = 0$. **Null energy condition** along x_0: $\rho + p_0 \ge 0$.
- **sympy symbol**: a letter that stands for any number; ‘ad1‘ and ‘ad2‘ stand for $a_4' = da_4/dx_4$ and $a_4'' = d^2a_4/dx_4^2$.
- **PASS line**: a printed line that says a check passed; "reproduces" names the Revision record (report file and check name) that found the same result.

Text cell:

```
## 4. The physical and mathematical situation

The author's metric (the primordial gravitational field) is diagonal:

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}s,\ e^{2a_4}s,\ e^{2a_4}s,\ -1,\
-e^{-2a_4}s,\ -e^{-2a_4}s,\ -e^{-2a_4}s\big),\qquad
s = \sin^{1/3} z,\quad z = 6 H x_0 \in (0, \pi/2),$$

in the order $x_0, \dots, x_7$, with $a_4 = a_4(x_4)$ and a constant $H > 0$. This is
```

```
the metric of 2026-10-14 on its background $b_4 = 1$: the second function
$b_4(x_4)$ multiplies the three extra-time components (section 10 says how the
notebook reads the Rust record, which keeps $b_4$ general). Its signs are
$(+,+,+,+,-,-,-,-)$: four space-like directions ($x_0, x_1, x_2, x_3$) and four
time-like ones ($x_4, \dots, x_7$), the signature (4,4).

The field equations of Einstein-Lovelock gravity are

$$\sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda \delta^\mu_\nu
= \kappa T^\mu{}_\nu,\qquad E_{(k)}{}^h{}_j = -\frac{P_{(k)}{}^h{}_j}{2^{k+1}},$$

$$P_{(k)}{}^h{}_j = \delta^{h h_1 \dots h_{2k}}_{j j_1 \dots j_{2k}}
R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}$$

(a sum over every repeated index), with the source

$$T^\mu{}_\nu = \mathrm{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0)
+ q_{40}\ (\mu = x_4, \nu = x_0) + q_{04}\ (\mu = x_0, \nu = x_4).$$

Every statement this notebook checks is an exact algebraic identity (status
PROVED): sympy computes with symbols, not with rounded numbers. The plots
evaluate the exact formulas at chosen numbers, in units in which $H = 1$.
```

Text cell:

```
## 5. The Revision records this notebook reproduces

The Revision record contains two independent derivations of these equations (one
in the Wolfram Language, one in sympy) and an independent check by the lead. Each
writes a report file: a list of checks with a name and a verdict. The next cell
defines a helper that looks up a check by its name, and the helper ‘reproduces‘:
a check that passes only when this notebook’s own result holds AND the record
lists the named check with the verdict PASS. ‘reproduces‘ collects its two printed
lines (PASS and reproduces) in a text buffer and prints them with one call, so
that they always stay together in the output. Finally the cell prints, for each of
the four reports, how many of its checks passed, and checks that every one did:
a record with a failed check stops the notebook here. The numbers of checks are
printed, not fixed in advance, because a record may gain checks when it is
extended.
```

## 6. The metric in sympy

The next cell makes the symbols: $H$ (positive), $z = 6Hx_0$ (positive; we work on
the patch $0 < z < \pi/2$), the time $x_4$ and the unknown function $a_4(x_4)$. Then
it writes the eight diagonal entries of the metric as a Python list ‘g‘ (position 0
is $g_{11}$, position 7 is $g_{00}$) and prints them. sympy writes a power as ‘**‘
and the function $a_4(x_4)$ as ‘a4(x4)‘.
```

In [3]:

```
import itertools  # loops over all combinations of indices

import numpy as np  # arrays of numbers, used for the plots
import sympy as sp  # exact algebra with symbols

H = sp.symbols("H", positive=True)  # the constant H of the metric, H > 0
z = sp.symbols("z", positive=True)  # the hidden angle z = 6 H x0, 0 < z < pi/2
x4 = sp.symbols("x4", real=True)  # the time x4
a4 = sp.Function("a4")(x4)  # the unknown function a4(x4)
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # positions 0..7
N = 8  # the number of dimensions
warp = sp.sin(z) ** sp.Rational(1, 3)  # the warp factor sin(z)^(1/3)
g = ([sp.cot(z) ** 2]  # g00 = cot(z)^2: the hidden direction
     + [sp.exp(2 * a4) * warp] * 3  # g11 = g22 = g33: 3-space, factor e^(2 a4)
     + [sp.Integer(-1)]  # g44 = -1: the time x4
     + [-sp.exp(-2 * a4) * warp] * 3)  # g55 = g66 = g77: extra times, e^(-2 a4)
for name, entry in zip(NAMES, g):
    say(f"g[{name},{name}] = {entry}")
```

Out [3]:

```
g[x0,x0] = cot(z)**2
g[x1,x1] = exp(2*a4(x4))*sin(z)**(1/3)
g[x2,x2] = exp(2*a4(x4))*sin(z)**(1/3)
g[x3,x3] = exp(2*a4(x4))*sin(z)**(1/3)
g[x4,x4] = -1
g[x5,x5] = -exp(-2*a4(x4))*sin(z)**(1/3)
g[x6,x6] = -exp(-2*a4(x4))*sin(z)**(1/3)
g[x7,x7] = -exp(-2*a4(x4))*sin(z)**(1/3)
```

Text cell:

```
The next cell checks two facts. (1) The signs of the diagonal entries, at any
point (here $a_4 = 0$, $z = \pi/4$), are $(+,+,+,+,-,-,-,-)$. (2) The determinant
of a diagonal matrix is the product of its diagonal entries:
$\det g = (e^{2a_4}s)^3 \cdot (-1) \cdot (-e^{-2a_4}s)^3 \cot^2 z
= s^6 \cot^2 z = \sin^2 z \cot^2 z = \cos^2 z$, because $e^{6a_4} e^{-6a_4} = 1$ and
$(-1)(-1)^3 = 1$. So $\sqrt{|\det g|} = \cos z$ (positive on the patch) does not
depend on $a_4$: the volume factor $e^{3a_4}$ of the inflating 3-space and
$e^{-3a_4}$ of the deflating extra times cancel.
```

In [4]:

```
point = {a4: 0, z: sp.pi / 4}  # any point of the patch gives the same signs
signs = [int(sp.sign(entry.subs(point))) for entry in g]
say(f"signs of the diagonal entries: {signs}")

```
## 7. Derivatives and the Christoffel symbols

The metric depends on $x_4$ and on $x_0$ only, and on $x_0$ only through
$z = 6Hx_0$. By the chain rule $\partial/\partial x_0 = (dz/dx_0)\,\partial/\partial z
= 6H\,\partial/\partial z$. The function ‘d(expr, mu)‘ below takes the partial
derivative with respect to the coordinate at position ‘mu‘.

For a diagonal metric the Christoffel symbols
$\Gamma^a{}_{bc} = \tfrac12 g^{ad}(\partial_b g_{dc} + \partial_c g_{db}
- \partial_d g_{bc})$ reduce (only $d = a$ survives, and $g^{aa} = 1/g_{aa}$) to

$$\Gamma^a{}_{bc} = \frac{1}{2g_{aa}}\big(\delta_{ac}\,\partial_b g_{aa}
+ \delta_{ab}\,\partial_c g_{aa} - \delta_{bc}\,\partial_a g_{bb}\big)$$

(no sum over $a$ or $b$). The cell computes all $8^3 = 512$ of them, counts those
that are not zero (37: the 25 distinct ones printed by the cell after it, 12 of
which appear twice because $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$ with $b \ne c$) and
checks that symmetry.
```

In [5]:

```
def d(expr, mu):
    """The partial derivative of expr with respect to the coordinate at position
    mu (0..7 for x0..x7); d/dx0 = 6 H d/dz by the chain rule."""
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7

Gamma = [[[sp.Integer(0)] * N for _ in range(N)] for _ in range(N)]  # 512 zeros
for a, b, c in itertools.product(range(N), repeat=3):  # every index triple
    value = 0
```

```
    if a == c:
        value += d(g[a], b)
    if a == b:
        value += d(g[a], c)
    if b == c:
        value -= d(g[b], a)
    Gamma[a][b][c] = value / (2 * g[a])  # Gamma^a_bc of a diagonal metric
nonzero = [(a, b, c) for a, b, c in itertools.product(range(N), repeat=3)
           if Gamma[a][b][c] != 0]

## 8. The Riemann tensor

The Riemann tensor in the sign convention of Misner, Thorne and Wheeler (MTW) is

$$R^a{}_{bmn} = \partial_m \Gamma^a{}_{bn} - \partial_n \Gamma^a{}_{bm}
+ \Gamma^a{}_{me}\Gamma^e{}_{bn} - \Gamma^a{}_{ne}\Gamma^e{}_{bm}$$

(sum over $e$), and with the second index raised,
$R^{ab}{}_{mn} = g^{bb} R^a{}_{bmn}$. It is antisymmetric in $(a, b)$ and in
$(m, n)$, so only $a \ne b$, $m \ne n$ can be nonzero.

To bring every component to one canonical form, the helper ‘clean‘ writes every
function of $z$ through $c = \cot z > 0$: $\sin z = 1/\sqrt{1 + c^2}$,
$\cos z = c/\sqrt{1 + c^2}$, $\tan z = 1/c$ (from $\cot z = \cos z/\sin z$ and
$\sin^2 z + \cos^2 z = 1$), first expanding $\sin 2z = 2\sin z\cos z$. In the code
$c$ is called ‘cz‘.
```

In [7]:

```
cz = sp.symbols("cz", positive=True)  # cz = cot z > 0 on the patch
TRIG = {sp.sin(z): 1 / sp.sqrt(1 + cz ** 2), sp.cos(z): cz / sp.sqrt(1 + cz ** 2),
```

```
        sp.tan(z): 1 / cz, sp.cot(z): cz}  # every function of z through cot z

def clean(expr):
    """expr in canonical form: derivatives of a4 as ad1, ad2, ad3; functions of z
    through cz; powers combined; common factors cancelled; expanded."""
    expr = sp.expand_trig(derivatives_as_symbols(expr)).subs(TRIG)
    return sp.expand(sp.cancel(sp.powsimp(sp.expand(expr), force=True)))

R = {}  # R[(a, b, m, n)] = R^{ab}_{mn}; only the components that are not zero
for a, b, m, n in itertools.product(range(N), repeat=4):
    if a == b or m == n:
        continue  # antisymmetry: zero when the two indices of a pair are equal
    value = (d(Gamma[a][b][n], m) - d(Gamma[a][b][m], n)
             + sum(Gamma[a][m][e] * Gamma[e][b][n] - Gamma[a][n][e] * Gamma[e][b][m]
                   for e in range(N)))  # R^a_bmn in the MTW convention

## 10. The three Lovelock tensors with the generalized Kronecker delta

The GKD $\delta^{h_1 \dots h_n}_{j_1 \dots j_n}$ is the determinant of the
$n \times n$ matrix of ordinary Kronecker deltas $\delta^{h_r}_{j_s}$. That
determinant is $0$ when two upper (or two lower) indices are equal (two equal
rows), and otherwise the sign of the permutation that turns the upper list into
the lower list (or $0$ when the two lists hold different indices). The next cell
implements it by counting *inversions*: pairs of positions that appear in the
wrong order. It prints three small examples and checks that 9 indices in 8
dimensions always give 0 (two of them must be equal): so there is no fourth
Lovelock tensor in 8 dimensions.
```

In [14]:

```
def gkd(upper, lower):

Text cell:

```
In $P_{(k)}{}^h{}_j$ every curvature factor $R^{j_1 j_2}{}_{h_1 h_2}$ appears with
its index pairs in both orders. Exchanging $j_1, j_2$ changes the sign of $R$ and
of the GKD (one more inversion), so both orders give the same term; the same holds
for $h_1, h_2$. Hence the full sum is $4^k$ times the sum over the 39 components
with $j_1 < j_2$ and $h_1 < h_2$. The next cell does this sum for $k = 1, 2, 3$,
together with the Lovelock scalar $L_{(k)}$ (the same sum without $h$ and $j$).
To multiply fast, each component, a Laurent polynomial in $\cot z$, is stored as
a sympy polynomial in $H, a_4', a_4'', \cot z$ and $t = \tan z = 1/\cot z$.
```

The Rust program ‘lovelock_gkd‘ of the GKD record stored every component of
$P_{(k)}{}^h{}_j$ as a list of monomials: a fraction and the 13 exponents of $H$,
$a_4’, a_4’’, a_4’’’, a_4’’’’$, $e^{a_4}$, $\sin^{1/3} z$, $\cot z$, $b_4^{1/2}$ and
$b_4’, b_4’’, b_4’’’, b_4’’’’$. The program computes the author’s metric with the
second function $b_4(x_4)$ of 2026-10-14; this notebook works at $b_4 = 1$, so
‘from_monomials‘ keeps only the monomials without a derivative of $b_4$ (the others
vanish at $b_4 = 1$) and sets $b_4^{1/2} = 1$. The same is done with the scalars
$L_{(k)}$ in the cell before (‘b4[x4]‘ becomes 1, its derivatives 0). The next
cell rebuilds all $3 \times 64$ components from those lists and compares them with
ours; it also compares the four distinct components of each $E_{(k)}$ with the
Wolfram record ‘a4-equations.json‘.
```

```
**An independent route to $E_{(2)}$.** The Gauss-Bonnet tensor has a classical
formula (Lanczos), written here with one index up:

$$H^\mu{}_\nu = 2\big(R\,R^\mu{}_\nu - 2R^\mu{}_a R^a{}_\nu
- 2R^{\mu a}{}_{\nu b} R^b{}_a + R^{\mu a}{}_{bc} R^{bc}{}_{\nu a}\big)
- \tfrac12\delta^\mu_\nu\big(R^2 - 4R^a{}_b R^b{}_a
+ R^{ab}{}_{cd} R^{cd}{}_{ab}\big).$$

It uses no GKD. The next cell computes it from our Riemann tensor for a general
$a_4$ and checks that it equals $E_{(2)}$ in all 64 components. For the linear
member ($a_4' = AH$, $a_4'' = 0$) it then reproduces the lead's numbers
$H^{x_4}{}_{x_4} = -H^4(36A^4 + 120A^2 + 420)$ and
$H^{x_1}{}_{x_1} = 12H^4(A^4 + 14A^2 - 15)$.
```

**The constraint and the evolution equation are linked (Bianchi identity).**
$e_{44}$ depends on $x_4$ only through $a_4'$, so by the chain rule
$\tfrac{d}{dx_4} e_{44} = \tfrac{\partial e_{44}}{\partial a_4'}\,a_4''$. The next
cell checks $\tfrac{d}{dx_4} e_{44} = 3a_4'(e_{11} - e_{55})$: the derivative of
the constraint is $3a_4'$ times the evolution equation. Hence, when the source
obeys $\rho' = -3a_4'(p_3 - p_t)$ (section 12), the constraint stays true along
a solution of the evolution equation. The cell also compares the four component
equations, $F$ and the algebraic condition with the Wolfram record.

## 12. The conservation law of the source

The Bianchi identity makes the divergence of the left-hand side zero, so the field
equations can hold only if the source has zero divergence too. The next cell
computes $\nabla_\mu T^\mu{}_\nu$ for a general source whose seven parts
$\rho, p_3, p_t, p_0, q_{40}, q_{04}$ are arbitrary functions of $x_4$ and $x_0$,
and compares it with the record:

$$\nabla_\mu T^\mu{}_{x_4} = -\partial_4\rho - 3a_4'(p_3 - p_t)
+ \partial_0 q_{04} - 6H\tan z\, q_{04},$$
$$\nabla_\mu T^\mu{}_{x_0} = \partial_0 p_0 + 3H\cot z\,(2p_0 - p_3 - p_t)
+ \partial_4 q_{40},$$

and zero for the six other $\nu$. With an $x_0$-independent source and
$q_{40} = q_{04} = 0$ this is $\rho' = -3a_4'(p_3 - p_t)$ and
```

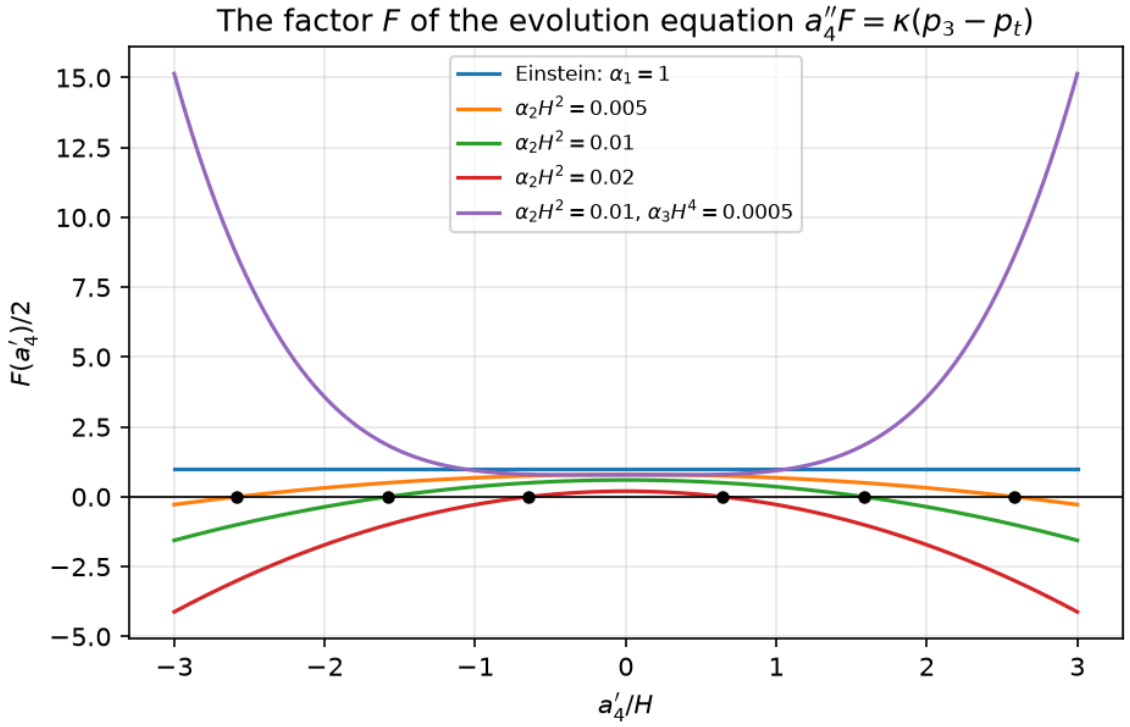

Figure 322: The factor $F(a_4')$ of the evolution equation $a_4'' F(a_4') = \kappa(p_3 - p_t)$, divided by 2, as a function of a_4'/H (units $H = 1$) for Einstein gravity ($F = 2$, flat line), for Einstein-Gauss-Bonnet gravity with $\alpha_2 H^2 = 0.005$, 0.01, 0.02, and with a third-order coupling $\alpha_3 H^4 = 0.0005$ added. Black dots mark the zeros of the Gauss-Bonnet curves, at $(a_4')^2 = (1 - 40\alpha_2 H^2)/(24\alpha_2)$: there the evolution equation cannot be solved for a_4''. The third-order term lifts the curve again at large a_4'. (Notebook 12a, figure 4.)

```
$p_3 + p_t = 2p_0$: the energy of the source changes only when the 3-space and the
extra-time pressures differ, and the hidden equation repeats the algebraic
condition.
```

## 13. Einstein gravity: no vacuum, and the null energy condition along $x_0$

In Einstein gravity ($\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$) the equations read

$$3(a_4')^2 + 21H^2 + \Lambda = -\kappa\rho,\qquad 2a_4'' = \kappa(p_3 - p_t),
\qquad -3(a_4')^2 + 15H^2 + \Lambda = \kappa p_0.$$

Adding the first and the third: $-\kappa\rho + \kappa p_0 = 36H^2 + 2\Lambda$.
Subtracting the first from the third: $\kappa(\rho + p_0) = -6(a_4')^2 - 6H^2$,
which is negative for every $a_4$ and every $\Lambda$: the source always violates
```

```
the null energy condition along the null direction $x_4 + x_0$ (for $\kappa > 0$).
A vacuum ($T = 0$) would need $6(a_4')^2 + 6H^2 = 0$, impossible for real $a_4'$
and $H > 0$. The next cell checks both and lets sympy solve the vacuum equations:
the only solutions have the imaginary slope $a_4' = \pm iH$.
```

In [26]:

```
EINSTEIN = {alpha1: 1, alpha2: 0, alpha3: 0}

## 14. The linear member $a_4 = A H x_4 + a_0$

For $a_4 = AHx_4 + a_0$ we have $a_4' = AH$ and $a_4'' = 0$: 3-space grows like
$e^{AHx_4}$ and the extra times shrink like $e^{-AHx_4}$ (exponential deflation
for $A > 0$). The next cell checks that then $p_3 = p_t = p_0 =: p$ (the three
pressures are equal) and that $\rho$ and $p$ are constants; it prints $\kappa\rho$
and $\kappa p$ and checks that they contain $A$ only through $A^2$: the equations
do not distinguish deflating extra times ($A > 0$) from inflating ones
($A < 0$). Deflation is a choice of sign, an initial condition, not a consequence
of the equations.
```

In [28]:

```
reproduces(sp.expand((e11 - e00).subs(LINEAR)) == 0
           and sp.expand((e55 - e00).subs(LINEAR)) == 0,

```
**The vacuum of the linear member.** A vacuum needs $\rho = p = 0$, so in
particular $e_{44} = e_{00}$. The next cell factors
$e_{44} - e_{00} = 6(A^2 + 1)H^2\,V$ with the polynomial

$$V = \alpha_1 - 8\alpha_2H^2(A^2 + 5) + \alpha_3 H^4(72A^4 + 144A^2 + 360).$$

In Einstein gravity $V = 1$: no vacuum. In Einstein-Gauss-Bonnet gravity
($\alpha_1 = 1$, $\alpha_3 = 0$) $V = 0$ gives
$A^2 = (1 - 40\alpha_2H^2)/(8\alpha_2H^2)$, a real $A$ only for
$0 < \alpha_2H^2 \le 1/40$. Because $e_{44}$ and $e_{00}$ contain no $a_4''$, the
same factorisation holds for EVERY $a_4$ with $AH$ replaced by $a_4'$:
$\kappa(\rho + p_0) = -6((a_4')^2 + H^2)\,V$. The cell also compares $\rho$, $p$
and $V$ with the record.

PASS all five figure files exist
ALL 59 CHECKS PASSED (notebook 12a)
```

Text cell:

```
## 16. What this notebook showed

- From the metric alone, sympy finds 37 nonzero Christoffel symbols and 156 nonzero
  curvature components $R^{ab}{}_{mn}$ (39 with $a < b$, $m < n$), none of which
  contains the warp factor or $e^{a_4}$ (PROVED, as in the Revision record).
- The Einstein tensor is diagonal with four distinct components, and the three
  Lovelock tensors built with the generalized Kronecker delta agree, in all 64
  components, with the Rust program and the Wolfram record; $E_{(2)}$ equals the
  classical Gauss-Bonnet tensor; each $E_{(k)}$ has zero divergence (PROVED).
- The field equations reduce to a constraint ($x_4$), an evolution equation
  $a_4''F(a_4') = \kappa(p_3 - p_t)$, a hidden equation ($x_0$), and conditions on
  the source: $p_3 + p_t = 2p_0$, no dependence on $x_0$, no mixed components
  (PROVED).
- The derivative of the constraint is $3a_4'$ times the evolution equation, and
  the source must obey $\rho' = -3a_4'(p_3 - p_t)$ (PROVED).
- In Einstein gravity there is no vacuum for $H > 0$, and every source has
  $\kappa(\rho + p_0) = -6((a_4')^2 + H^2) < 0$ (PROVED).
- For the linear member $a_4 = AHx_4 + a_0$ the three pressures are equal and
  constant, and the equations contain $A$ only as $A^2$: the exponential deflation
  of the extra times ($A > 0$) is a choice of sign, not selected by the equations
  (PROVED).
```

12.16 Line-by-line walk-through of Notebook 12a

The notebook has 30 code cells, In [1] to In [30]. This section explains every line of every one of them, in order. A line or a group of lines is quoted, then explained. Where a cell repeats a pattern already explained, we say so and explain only what is new.

In [1], the set-up cell. Every line that starts with `#` is a **comment**, which Python skips. The first comment lines of the cell are the complete run instructions of Section 12.14, so that the notebook file carries its own instructions. The code starts after the line that announces THE SET-UP (the same in every notebook of this book; it computes no physics).

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module**, a part of Python or of a package, so that the code can use it. `json`, `os`, `textwrap` and `pathlib` come with Python. `from pathlib import Path` takes the one name `Path` out of `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell.

```
NOTEBOOK_ID = "12a"  # this notebook: chapter 12, example a
```

A **variable** is a name for a value; this line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"12a"`. The figure files are named after it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. (In the notebook the function also has a **docstring**, the text in triple quotes under the `def` line, which says what it does; it is left out here.) `Path.cwd()` is the folder in which Jupyter runs the notebook and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with them (the star unpacks a list into another list). The `for` loop visits these folders one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
REPO = find_repository_root()
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The first line calls the function and names its result `REPO`; it is never printed, because it differs from computer to computer while the printed output of a notebook must not. The second line chooses where files are written: `os.environ` holds the **environment variables** of the program (named texts it receives from the computer), and `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and `str(REPO)` otherwise. When you run the notebook it is not set, so files go into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small functions (docstrings left out). `repository_file` gives the full path of a repository file, for reading a Revision record. `output_file` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates its folder and any missing folder above it, and does nothing if it exists.

```
def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters (the width of a page of the book); `textwrap.fill` breaks the text at blanks and starts every line after the first with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings, so that the figures are the same on every computer. `plt.rcParams.update({...})` sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid (`grid.alpha` 0.3 means 30 per cent opaque). The braces make a **dictionary**: pairs `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: a name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/12a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty JSON dictionary and a line end into the captions file (the comment lines above it in the notebook say so); `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

(Shown without its docstring and its three comment lines.) `setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of

figures so far: the figures are numbered 1, 2, 3, and a cell run twice keeps its number. The file name is the notebook id, the number and the name, for example `12a_1_riemann_matrix.png`. `fig.savefig` writes a PNG file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time. The caption is stored, the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys), `display(Image(...))` shows the saved picture, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection in square brackets). `check` is the function behind every check: if `condition` is false (`False`), `raise AssertionError(...)` stops the notebook with an error naming the check (an `if` is used instead of the statement `assert`, because Python started with the option that optimises skips every `assert`); otherwise the name is appended to `PASSED` and the line PASS name is printed, followed by a second line naming the Revision record when `record` is given. `record=None` makes that argument optional.

```
def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; `(f" {unit}" if unit else "")` adds the unit when one is given. `all_checks_passed` prints the last line of the notebook; `len(PASSED)` is the number of checks that passed. The last statement prints the one output line of In [1].

In [2], the Revision records.

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory
```

Two modules of Python: `contextlib` provides `redirect_stdout`, which sends everything that `print` writes into another place, and `io` provides `StringIO`, a text buffer held in memory.

```
PY = "Revision/field_equations_a4/reports/python-a4-report.json"  # sympy record
WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"  # Wolfram record
LEAD = "Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json"  # lead check
EMT = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
EQUATIONS = "Revision/field_equations_a4/a4-equations.json"  # the equations
LOVELOCK = "Revision/gkd_lovelock/results/lovelock-tensors.json"  # Rust GKD output
```

Six short names for the six record files the notebook reads: the sympy report and the Wolfram report of the field equations, the lead's two independent reports, the equations themselves (written by the Wolfram verifier) and the Lovelock tensors written by the Rust program `lovelock_gkd`.

```
def read_json(relative):
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

def record_verdict(report_file, name):
    for entry in read_json(report_file)["checks"]:
        if entry["name"] == name:
            return entry["verdict"]
    return None
```

`read_json` reads a file of the repository as text and turns it into Python dictionaries and lists with `json.loads`. Every report holds a list under the key `"checks"`; each entry is a dictionary with a `"name"` and a `"verdict"`. `record_verdict` walks through that list and returns the verdict of the check with the given name, or `None` if there is no such check.

```
def reproduces(condition, name, report_file, record_name):
    found = record_verdict(report_file, record_name) == "PASS"
    lines = io.StringIO()  # a text buffer
    with contextlib.redirect_stdout(lines):  # print() now writes into the buffer
        check(condition and found, name, record=f"{report_file}, check {record_name}")
    print(lines.getvalue(), end="")  # all lines at once
```

`reproduces` is a check that passes only when two things are true: the notebook's own result (`condition`) and the record's verdict PASS for the named check (`found`). `with contextlib.redirect_stdout(lines):` makes every `print` inside the indented block write into the buffer `lines` instead of the screen; after the block, `print(lines.getvalue(), end="")` prints the collected PASS and reproduces lines with one call (`end=""` adds no extra line end), so the two lines always stay together.

```
for report_file in (PY, WL, LEAD, EMT):
    verdicts = [entry["verdict"] for entry in read_json(report_file)["checks"]]
    passed = verdicts.count("PASS")  # how many checks of the record passed
    say(f"{report_file}: {passed} of {len(verdicts)} checks PASS")
    check(len(verdicts) > 0 and passed == len(verdicts),
          f"every check of the record {Path(report_file).name} passed")
```

For each of the four reports, a **list comprehension** collects the verdicts of all its checks, `.count("PASS")` counts the PASS verdicts, and `say` prints this count together with the number of checks

of the report. `check` then requires that the report has at least one check and that every one of them passed; `Path(report_file).name` is the last part of the path, the file name, which names the report in the PASS line. So Out [2] shows, for each of the four reports by name, how many checks it has and that all of them passed, followed by a PASS line. This text does not repeat the counts: a report may gain checks when its record is extended, and Out [2] always shows the counts of the reports the notebook was run with.

In [3], the metric.

```
import itertools  # loops over all combinations of indices

import numpy as np  # arrays of numbers, used for the plots
import sympy as sp  # exact algebra with symbols
```

`itertools` (part of Python) produces combinations of indices; `numpy` (as `np`) computes with arrays of floating-point numbers; `sympy` (as `sp`) computes exactly with symbols.

```
H = sp.symbols("H", positive=True)  # the constant H of the metric, H > 0
z = sp.symbols("z", positive=True)  # the hidden angle z = 6 H x0, 0 < z < pi/2
x4 = sp.symbols("x4", real=True)  # the time x4
a4 = sp.Function("a4")(x4)  # the unknown function a4(x4)
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # positions 0..7
N = 8  # the number of dimensions
warp = sp.sin(z) ** sp.Rational(1, 3)  # the warp factor sin(z)^(1/3)
```

`sp.symbols` makes a symbol, a letter that stands for any number; `positive=True` and `real=True` tell sympy what kind of number, which lets it simplify safely (for example $\sqrt{H^2} = H$ for $H > 0$). `sp.Function("a4")(x4)` is an unknown function of x_4: sympy can differentiate it without knowing it. `NAMES` lists the coordinates in the author's order; `N = 8`. `sp.Rational(1, 3)` is the exact fraction 1/3 (the floating-point number 0.333... would introduce rounding), and `**` means "to the power".

```
g = ([sp.cot(z) ** 2]  # g00 = cot(z)^2: the hidden direction
     + [sp.exp(2 * a4) * warp] * 3  # g11 = g22 = g33: 3-space, factor e^(2 a4)
     + [sp.Integer(-1)]  # g44 = -1: the time x4
     + [-sp.exp(-2 * a4) * warp] * 3)  # g55 = g66 = g77: extra times, e^(-2 a4)
for name, entry in zip(NAMES, g):
    say(f"g[{name},{name}] = {entry}")
```

A list times 3 repeats it three times, and `+` joins lists; so `g` is the list of the eight diagonal entries of Section 12.3, in the order $x_0, \ldots, x_7$. `zip(NAMES, g)` pairs each name with its entry, and the loop prints the eight lines of Out [3].

In [4], signature and determinant.

```
point = {a4: 0, z: sp.pi / 4}  # any point of the patch gives the same signs
signs = [int(sp.sign(entry.subs(point))) for entry in g]
say(f"signs of the diagonal entries: {signs}")
check(signs == [1, 1, 1, 1, -1, -1, -1, -1],
      "the signature is (4,4): eta = diag(+,+,+,+,-,-,-,-) in the order x0..x7")
```

`entry.subs(point)` replaces a_4 by 0 and z by $\pi/4$ in an entry; `sp.sign` gives $+1$ or -1 and `int` makes it a Python integer. The check compares the list of signs with the signature (4,4).

```
det_g = sp.Mul(*g)  # the product of the eight diagonal entries
say(f"det g = {sp.simplify(det_g)}")
reproduces(sp.simplify(det_g - sp.cos(z) ** 2) == 0,
           "det g = cos(z)^2, so sqrt|det g| = cos z, independent of a4",
           WL, "sqrt_abs_det_g_is_cos_z")
```

`sp.Mul(*g)` multiplies all entries of the list (the star passes the eight entries as eight separate arguments). `sp.simplify` reduces the product to `cos(z)**2`, the result of Section 12.3, and `reproduces` checks that $\det g - \cos^2 z$ simplifies to 0 and that the Wolfram record has the same check.

In [5], the Christoffel symbols.

```
def d(expr, mu):
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7
```

The function `d` is the partial derivative with respect to the coordinate at position `mu` (docstring left out): for position 3 (x_4) it is `sp.diff(expr, x4)`; for position 7 (x_0) it is $6H\,\partial/\partial z$ (the chain rule of Section 12.4); for every other position it is zero, because nothing depends on those coordinates.

```
Gamma = [[[sp.Integer(0)] * N for _ in range(N)] for _ in range(N)]  # 512 zeros
for a, b, c in itertools.product(range(N), repeat=3):  # every index triple
    value = 0
    if a == c:
        value += d(g[a], b)
    if a == b:
        value += d(g[a], c)
    if b == c:
        value -= d(g[b], a)
    Gamma[a][b][c] = value / (2 * g[a])  # Gamma^a_bc of a diagonal metric
```

The first line makes a nested list of $8 \times 8 \times 8 = 512$ exact zeros, `Gamma[a][b][c]` (the underscore `_` is a loop variable whose value is not used). `itertools.product(range(N), repeat=3)` produces all 512 triples (a, b, c). The body is the diagonal formula of Section 12.4: the three `if` lines add $\delta_{ac}\partial_b g_{aa}$, add $\delta_{ab}\partial_c g_{aa}$ and subtract $\delta_{bc}\partial_a g_{bb}$ (`+=` adds to a variable, `-=` subtracts), and the last line divides by $2g_{aa}$.

```
nonzero = [(a, b, c) for a, b, c in itertools.product(range(N), repeat=3)
           if Gamma[a][b][c] != 0]
say(f"{len(nonzero)} of the 512 Christoffel symbols are not zero")
check(len(nonzero) == 37,
      "37 nonzero Christoffel symbols (25 distinct, 12 of them twice)")
check(all(Gamma[a][b][c] == Gamma[a][c][b] for a, b, c in nonzero),
      "Gamma^a_bc = Gamma^a_cb (symmetric in the two lower indices)")
```

The list comprehension keeps the triples whose symbol is not zero (`!=` means "is not equal to"); `len` counts them: 37, as counted in Section 12.4. `all(...)` is true when the condition holds for every triple of the list; the second check is the symmetry in the two lower indices.

In [6], the symbols printed.

```
ad1, ad2, ad3 = sp.symbols("ad1 ad2 ad3", real=True)

def derivatives_as_symbols(expr):
    expr = expr.subs(sp.Derivative(a4, (x4, 3)), ad3)  # highest derivative first
    expr = expr.subs(sp.Derivative(a4, (x4, 2)), ad2)
    return expr.subs(sp.Derivative(a4, x4), ad1)

def readable(expr):
    return sp.simplify(derivatives_as_symbols(expr))
```

Three plain symbols stand for a_4', a_4'' and a_4'''. `derivatives_as_symbols` replaces the derivatives of the function a_4 by them, the highest derivative first (a second derivative contains the first derivative inside it, so replacing the first derivative first could break it). `readable` also simplifies, for printing.

```
for a, b, c in nonzero:
    if b <= c:  # print each symmetric pair once
        say(f"Gamma^{NAMES[a]}_{NAMES[b]}{NAMES[c]} = {readable(Gamma[a][b][c])}")
```

The loop prints each of the 25 distinct symbols once (`b <= c` skips the second member of each symmetric pair). Out [6] shows exactly the symbols derived by hand in Section 12.4, for example `Gamma^x5_x4x5 = -ad1` and `Gamma^x0_x0x0 = -12*H/sin(2*z)`.

In [7], the Riemann tensor.

```
cz = sp.symbols("cz", positive=True)  # cz = cot z > 0 on the patch
TRIG = {sp.sin(z): 1 / sp.sqrt(1 + cz ** 2), sp.cos(z): cz / sp.sqrt(1 + cz ** 2),
        sp.tan(z): 1 / cz, sp.cot(z): cz}  # every function of z through cot z
```

A positive symbol `cz` stands for $\cot z$, and the dictionary `TRIG` says how to write each function of z through it: from $\cot z = \cos z / \sin z$ and $\sin^2 z + \cos^2 z = 1$ follow $\sin z = 1/\sqrt{1+\cot^2 z}$ and $\cos z = \cot z/\sqrt{1+\cot^2 z}$ on the patch.

```
def clean(expr):
    expr = sp.expand_trig(derivatives_as_symbols(expr)).subs(TRIG)
    return sp.expand(sp.cancel(sp.powsimp(sp.expand(expr), force=True)))
```

`clean` brings an expression to one canonical form (docstring left out): derivatives become `ad1`, `ad2`, `ad3`; `sp.expand_trig` writes $\sin 2z$ as $2\sin z\cos z$; `.subs(TRIG)` writes every function of z through `cz`; `sp.expand` multiplies out; `sp.powsimp(..., force=True)` combines powers of the same base (so that $e^{2a_4}e^{-2a_4}$ becomes 1 and powers of $1+\cot^2 z$ combine); `sp.cancel` cancels common factors of numerator and denominator; the last `sp.expand` multiplies out again. Two expressions that are equal then look equal.

```
R = {}  # R[(a, b, m, n)] = R^{ab}_{mn}; only the components that are not zero
for a, b, m, n in itertools.product(range(N), repeat=4):
    if a == b or m == n:
        continue  # antisymmetry: zero when the two indices of a pair are equal
    value = (d(Gamma[a][b][n], m) - d(Gamma[a][b][m], n)
             + sum(Gamma[a][m][e] * Gamma[e][b][n] - Gamma[a][n][e] * Gamma[e][b][m]
                   for e in range(N)))  # R^a_bmn in the MTW convention
    if value != 0:
        value = clean(value / g[b])  # raise the index b: multiply by g^bb
        if value != 0:
            R[(a, b, m, n)] = value
```

`R` starts as an empty dictionary; its keys will be index lists (a, b, m, n). The loop runs over all $8^4 = 4096$ index lists; `continue` skips those with $a = b$ or $m = n$, which are zero by antisymmetry. The expression for `value` is the definition of Section 12.5 term by term: two derivatives and the sum over e of the two products (`sum(... for e in range(N))` adds the expression for $e = 0, \ldots, 7$). If the result is not zero, dividing by g_{bb} raises the index b (multiplication by $g^{bb} = 1/g_{bb}$), `clean` simplifies, and a component that is still not zero is stored.

```
ordered = {key: value for key, value in R.items()
           if key[0] < key[1] and key[2] < key[3]}  # a < b and m < n
report("nonzero components R^ab_mn of the 4096", len(R))
report("nonzero components with a < b and m < n", len(ordered))
```

A **dictionary comprehension** keeps the components with $a < b$ and $m < n$ (`key[0]` is the first index of the key). The two RESULT lines report 156 and 39 (Section 12.5).

In [8], four facts about the curvature.

```
reproduces(len(R) == 156, "156 nonzero components R^ab_mn of the 4096",
           PY, "mixed_riemann_free_of_warp_and_a4")
reproduces(len(ordered) == 39, "39 nonzero components with a < b and m < n",
           WL, "mixed_riemann_free_of_warp_and_a4")
```

The two counts, compared with the sympy and the Wolfram record (both records state the counts in the detail of the named check).

```
free = all(not v.has(a4) and not v.has(z) and not v.has(sp.exp) for v in R.values())
reproduces(free, "R^ab_mn is free of the warp factor and of e^(a4)",
           PY, "mixed_riemann_free_of_warp_and_a4")
```

`v.has(x)` is true when the expression `v` contains `x` anywhere. The condition says that no component contains the function a_4, the angle z (so no warp factor) or an exponential.

```
laurent = all(sp.expand(v * cz).is_polynomial(H, ad1, ad2, cz) for v in R.values())
reproduces(laurent, "every R^ab_mn is a Laurent polynomial in cot z",
           PY, "riemann_entries_laurent")
```

Multiplying a component by $\cot z$ must give a polynomial in H, a_4', a_4'' and $\cot z$; then the component itself is a polynomial divided at most by $\cot z$, a **Laurent polynomial** in $\cot z$.

```
antisymmetric = all(R.get((b, a, m, n)) == -v and R.get((a, b, n, m)) == -v
                    for (a, b, m, n), v in R.items())
reproduces(antisymmetric, "R^ab_mn = -R^ba_mn = -R^ab_nm",
           PY, "riemann_pair_antisymmetry")
```

`R.get(key)` returns the stored value or `None` if the key is absent. For every stored component the exchanged components must be stored with the opposite value.

In [9], the 39 components grouped.

```
def pair_name(a, b):
    return NAMES[a] + NAMES[b]

groups = {}  # printed value -> the components that have it
for (a, b, m, n), value in ordered.items():
    label = f"{pair_name(a, b)}|{pair_name(m, n)}"
    groups.setdefault(str(value), []).append(label)
for value, members in groups.items():
    say(f"{value} ({len(members)}): " + " ".join(members))
```

`pair_name` joins two coordinate names, for example `x1x4`. The first loop files each component under its printed value: `groups.setdefault(str(value), [])` returns the list stored for this value, creating an empty one the first time, and `.append(label)` adds the label `x1x4|x1x4`. The second loop prints each value, the number of its members and the members joined by blanks. Out [9] is the table of Section 12.5: seven groups, of which two are the off-diagonal ones with `cz`.

In [10], figure 1: the Riemann tensor as a heat map.

```
PAIRS28 = [(a, b) for a in range(N) for b in range(a + 1, N)]  # the 28 pairs
SAMPLE = {H: 1, ad1: sp.Rational(3, 5), ad2: sp.Rational(3, 10),
          cz: 1 / sp.sqrt(3)}  # H = 1, a4' = 0.6, a4'' = 0.3, z = pi/3
table = np.zeros((28, 28))
for i, (a, b) in enumerate(PAIRS28):
    for j, (m, n) in enumerate(PAIRS28):
        if (a, b, m, n) in R:
            table[i, j] = float(R[(a, b, m, n)].subs(SAMPLE))
```

`PAIRS28` lists the 28 pairs $a < b$. `SAMPLE` is a sample point at which the exact components are evaluated: $H = 1$, $a_4' = 0.6$, $a_4'' = 0.3$ and $\cot z = 1/\sqrt{3}$, that is $z = \pi/3$. `np.zeros((28, 28))` is a 28 by 28 table of zeros. `enumerate` gives each pair together with its position `i` (or `j`); for every stored component the table entry becomes its value at the sample point, converted to a floating-point number by `float`.

```
limit = np.abs(table).max()  # the same scale for both signs
labels = [pair_name(a, b) for a, b in PAIRS28]
fig, ax = plt.subplots(figsize=(7.5, 6.6))
image = ax.imshow(table, cmap="RdBu_r", vmin=-limit, vmax=limit)
```

`limit` is the largest absolute value in the table. `plt.subplots` makes a figure and one pair of axes, 7.5 by 6.6 inches. `ax.imshow` draws the table as coloured squares with the colour map `RdBu_r` (blue for negative, white for zero, red for positive); `vmin=-limit, vmax=limit` make the scale symmetric, so that white means exactly zero.

```
ax.set_xticks(range(28))
ax.set_xticklabels(labels, rotation=90, fontsize=6)
ax.set_yticks(range(28))
ax.set_yticklabels(labels, fontsize=6)
ax.set_xlabel("lower index pair $(m, n)$")
ax.set_ylabel("upper index pair $(a, b)$")
ax.grid(False)
ax.set_title("Riemann tensor $R^{ab}{}_{mn}$ at $H=1$, $a_4'=0.6$, "
             "$a_4''=0.3$, $z=\\pi/3$")
fig.colorbar(image, ax=ax, shrink=0.8, label="value (units of $H^2$)")
```

These lines put a tick at each of the 28 positions on both axes and label it with the pair name (turned by 90 degrees on the horizontal axis), name the axes, switch off the grid (it would cover the squares), set the title (text between dollar signs is typeset as mathematics; a doubled backslash in a Python string is one backslash) and add a colour bar that translates colours into values.

```
save_figure(fig, "riemann_matrix",
            "The Riemann tensor $R^{ab}{}_{mn}$ of the author's metric as a 28 by "
            ...)
```

`save_figure` saves the figure as `12a_1_riemann_matrix.png` with its caption (printed in full in the notebook text; Python joins strings written next to each other into one). **What the figure shows.** Almost all the colour sits on the diagonal: the 27 pair curvatures of Section 12.5 (the diagonal square of x_4x_0 is white, because that pair curvature is zero). The few coloured squares off the diagonal are the 12 components that couple, for example, x_1x_4 with x_1x_0; they are proportional to Ha_4' and would vanish for a constant a_4.

In [11], Ricci, Ricci scalar and Einstein tensor.

```
Ricci = [[sp.expand(sum(R.get((a, h, a, j), 0) for a in range(N)))
          for j in range(N)] for h in range(N)]  # R^h_j
ricci_scalar = sp.expand(sum(Ricci[h][h] for h in range(N)))
G = [[sp.expand(Ricci[h][j] - (ricci_scalar / 2 if h == j else 0))
      for j in range(N)] for h in range(N)]  # G^h_j
```

The three definitions of Section 12.6. `R.get((a, h, a, j), 0)` returns 0 for a component that is not stored. `Ricci[h][j]` is the sum over a; `ricci_scalar` the sum of the diagonal; `G` subtracts half the Ricci scalar on the diagonal only (`x if condition else y` chooses between two values).

```
report("Ricci scalar R", ricci_scalar)
for h in range(N):
    say(f"G^{NAMES[h]}_{NAMES[h]} = {G[h][h]}")
```

The RESULT line shows $R = 6(a_4')^2 - 42H^2$ and the loop prints the eight diagonal components: exactly those derived by hand in Section 12.6.

In [12], the Einstein tensor compared with the records.

```
reproduces(all(G[h][j] == 0 for h in range(N) for j in range(N) if h != j),
           "G^h_j is diagonal (in particular G^x4_x0 = G^x0_x4 = 0)",
           LEAD, "einstein_off_diagonal_zero")
reproduces(G[1][1] == G[2][2] == G[3][3] and G[5][5] == G[6][6] == G[7][7],
           "G^x1_x1 = G^x2_x2 = G^x3_x3 and G^x5_x5 = G^x6_x6 = G^x7_x7",
           LEAD, "einstein_isotropy")
reproduces(not any(G[h][j].has(cz) for h in range(N) for j in range(N)),
           "every component of G is independent of x0",
           LEAD, "einstein_x0_independent")
```

Three structural checks against the lead's record: every off-diagonal component is zero (the cancellation of Section 12.6), the components are equal within 3-space and within the extra times (Python allows the chain `x == y == z`), and no component contains $\cot z$ (`any` is true when at least one element is true; `not any` when none is).

```
expected = {4: 3 * ad1 ** 2 + 21 * H ** 2, 1: ad2 - 3 * ad1 ** 2 + 15 * H ** 2,
            5: -ad2 - 3 * ad1 ** 2 + 15 * H ** 2, 0: -3 * ad1 ** 2 + 15 * H ** 2}
reproduces(all(sp.expand(G[i][i] - v) == 0 for i, v in expected.items()),
           "the four Einstein components agree with the record",
           PY, "einstein_components")
```

The dictionary `expected` holds the four distinct components, keyed by their positions (3 for x_4, 0 for x_1, 4 for x_5, 7 for x_0); the check requires each difference to expand to zero.

In [13], figure 2: the Einstein components.

```
u = np.linspace(-3.0, 3.0, 301)  # a4'/H
fig, ax = plt.subplots()
ax.plot(u, 3 * u ** 2 + 21, label="$G^{x_4}{}_{x_4}$ (constraint)")
ax.plot(u, 15 - 3 * u ** 2, color="black",
        label="$G^{x_0}{}_{x_0}$ $=$ $G^{x_1}{}_{x_1}$ $=$ $G^{x_5}{}_{x_5}$ "
              "at $a_4''=0$")
ax.plot(u, 15 - 3 * u ** 2 + 1, "--", label="$G^{x_1}{}_{x_1}$ at $a_4''=H^2$")
ax.plot(u, 15 - 3 * u ** 2 - 1, "--", label="$G^{x_5}{}_{x_5}$ at $a_4''=H^2$")
```

`np.linspace(-3.0, 3.0, 301)` makes 301 equally spaced values of a_4'/H from -3 to 3 (step 0.02). In units $H = 1$ the four formulas of Section 12.6 are evaluated on the whole array at once and drawn with `ax.plot(x, y, ...)`; the string of two hyphens makes a dashed line, and `label=` names the curve in the legend.

```
ax.set_xlabel("$a_4'/H$")
ax.set_ylabel("component of $G^\\mu{}_\\nu$ (units of $H^2$)")
ax.set_title("The Einstein tensor of the author's metric")
ax.legend(fontsize=8)
save_figure(fig, "einstein_components",
            ...)
```

Axis labels, title, legend, and `save_figure` with the caption printed in the notebook text. **What the figure shows.** The time component is a parabola that opens upwards and never falls below $21H^2$; the hidden component opens downwards. The two dashed curves lie a distance H^2 above and below the black one: only the difference of the 3-space and the extra-time components feels a_4'', which is why the evolution equation of Section 12.9 is their difference.

In [14], the generalized Kronecker delta.

```
def gkd(upper, lower):
    if len(set(upper)) != len(upper) or sorted(upper) != sorted(lower):
        return 0
    position = [upper.index(index) for index in lower]  # where each one sits
    inversions = sum(1 for i in range(len(position))
                     for j in range(i + 1, len(position))
                     if position[i] > position[j])
    return -1 if inversions % 2 else 1
```

`set(upper)` keeps each index once, so `len(set(upper)) != len(upper)` detects a repeated index; `sorted(upper) != sorted(lower)` detects two lists that do not hold the same indices; in both cases the delta is 0. Otherwise `position` lists where each lower index sits in the upper list (`upper.index(x)` is the position of `x`): this is the rearrangement. `inversions` counts the pairs of positions $i < j$ that appear in the wrong order. An even number of inversions means an even rearrangement (sign $+1$), an odd number an odd one (-1); `inversions % 2` is the remainder after division by 2.

```
say(f"gkd([1, 2], [1, 2]) = {gkd([1, 2], [1, 2])}, gkd([1, 2], [2, 1]) = "
    f"{gkd([1, 2], [2, 1])}, gkd([1, 1], [1, 1]) = {gkd([1, 1], [1, 1])}")
nine = list(range(8)) + [0]  # nine indices from eight values: one repeats
reproduces(gkd(nine, nine) == 0 and gkd(list(range(8)), list(range(8))) == 1,
           "a GKD of 9 indices in 8 dimensions is 0: P_(4) = 0",
           WL, "P4_vanishes_pigeonhole")
```

Three small examples are printed: 1, -1 and 0. Then a list of nine indices made of the eight values 0 to 7 and a repeated 0: its delta is 0, while the delta of the eight different indices with themselves is 1. This is the pigeonhole argument of Section 12.7.

In [15], the three Lovelock tensors.

```
tz = sp.symbols("tz", positive=True)  # tz = tan z = 1/cot z
GENERATORS = (H, ad1, ad2, cz, tz)
# xreplace replaces exactly the expression 1/cz by tz and leaves cz itself alone:
FACTORS = [(key, sp.Poly(value.xreplace({1 / cz: tz}), *GENERATORS))
           for key, value in ordered.items()]  # the 39 components as polynomials
```

To multiply thousands of products quickly, each of the 39 components is stored as a sympy **polynomial** (`sp.Poly`) in the five generators H, a_4', a_4'', $\cot z$ and a new symbol $t = \tan z$, listed in `GENERATORS`. The comment line says what the next line does: `value.xreplace({1 / cz: tz})` replaces exactly the expression $1/\cot z$ by t and leaves every $\cot z$ itself unchanged, so that no division is left and the component is a polynomial. `FACTORS` is the list of pairs (index list, polynomial).

```
def lovelock(k):
    zero = sp.Poly(0, *GENERATORS)
    P = [[zero] * N for _ in range(N)]
    L = zero
    terms = 0
```

The function `lovelock(k)` (docstring left out) starts with the zero polynomial, an 8 by 8 table `P` of zeros, a zero scalar `L` and a counter `terms`.

```
    for factors in itertools.product(FACTORS, repeat=k):
        lower = [i for key, _ in factors for i in key[0:2]]  # upper indices of R
        upper = [i for key, _ in factors for i in key[2:4]]  # lower indices of R
        if len(set(lower)) < 2 * k or len(set(upper)) < 2 * k:
            continue  # a repeated index: the GKD is zero
        terms += 1
```

`itertools.product(FACTORS, repeat=k)` produces every list of k components (39^k lists). For each, `lower` collects the two upper indices of each Riemann factor (`key[0:2]` is the first two entries of the key): in the formula of Section 12.7 these are the lower indices $j_1 \dots j_{2k}$ of the delta. `upper` collects the lower indices of the factors, the upper indices $h_1 \dots h_{2k}$ of the delta. A list with a repeated index is skipped, because its delta is zero; the others are counted.

```
        product = sp.Poly(4 ** k, *GENERATORS)  # the factor 4^k
        for _, poly in factors:
            product = product * poly
        L = L + gkd(upper, lower) * product
        for h, j in itertools.product(range(N), repeat=2):
            sign = gkd([h] + upper, [j] + lower)
            if sign:
                P[h][j] = P[h][j] + sign * product
```

The product of the k factors is multiplied by 4^k: each factor stands for its four orderings ($b < a$ or $n < m$ as well), which give the same contribution (the text cell before the cell explains why). The product, with the sign of the delta, is added to the scalar `L` and, for every pair (h, j) with a nonzero delta `gkd([h] + upper, [j] + lower)`, to `P[h][j]` (`if sign:` is true for $+1$ and -1, false for 0).

```
    back = {tz: 1 / cz}  # tan z back to 1/cot z
    P = [[sp.expand(P[h][j].as_expr().subs(back)) for j in range(N)]
         for h in range(N)]
    return P, sp.expand(L.as_expr().subs(back)), terms
```

At the end `.as_expr()` turns each polynomial back into an ordinary expression, t is replaced by $1/\cot z$ again, and the function returns the table, the scalar and the count.

```
P, Lscalar, E = {}, {}, {}
for k in (1, 2, 3):
    P[k], Lscalar[k], terms = lovelock(k)
    E[k] = [[sp.expand(-P[k][h][j] / 2 ** (k + 1)) for j in range(N)]
            for h in range(N)]  # E_(k) = -P_(k)/2^(k+1)
    say(f"k = {k}: {terms} lists of index pairs contribute; L_({k}) = {Lscalar[k]}")
```

For $k = 1, 2, 3$ the cell computes $P_{(k)}$, $L_{(k)}$ and the number of contributing lists, forms $E_{(k)} = -P_{(k)}/2^{k+1}$ and prints a line. Out [15] shows 39, 690 and 4410 contributing lists and the three Lovelock scalars; for example $L_{(1)} = 12(a_4')^2 - 84H^2$, which is twice the Ricci scalar.

In [16], the Lovelock tensors compared with the records.

```
reproduces(all(sp.expand(E[1][h][j] - G[h][j]) == 0
               for h in range(N) for j in range(N)),
           "E_(1) = G in all 64 components (P_(1) = -4 G)",
           PY, "P1_equals_minus_4_Einstein")
lovelock_json = read_json(LOVELOCK)
```

The first check is the statement $E_{(1)} = G$ of Section 12.7 in all 64 components. The next line reads the Rust record.

```
for k in (1, 2, 3):
    Ek = E[k]
    structure = (all(Ek[h][j] == 0 for h in range(N) for j in range(N) if h != j)
                 and Ek[1][1] == Ek[2][2] == Ek[3][3]
                 and Ek[5][5] == Ek[6][6] == Ek[7][7]
                 and not any(Ek[h][h].has(cz) for h in range(N)))
    reproduces(structure, f"E_({k}) diagonal, free of x0, isotropic in each group",
               PY, f"P{k}_structure")
```

For each k: the tensor is diagonal, equal within 3-space and within the extra times, and free of $\cot z$; compared with the record checks `P1_structure`, `P2_structure`, `P3_structure`.

```
    trace = sp.expand(sum(P[k][h][h] for h in range(N)) - (8 - 2 * k) * Lscalar[k])
    reproduces(trace == 0, f"trace identity sum_h P_({k})^h_h = (8 - {2 * k}) L_({k})",
               PY, f"P{k}_trace_identity")
```

The trace identity $\sum_h {P_{(k)}}^h{}_h = (8 - 2k)L_{(k)}$: summing the delta with $h = j$ over the $8 - 2k$ values of h that are not among the other $2k$ indices gives $8 - 2k$ times the scalar.

```
    text = (lovelock_json[f"L{k}"].replace("Derivative[1][a4][x4]", "ad1")
            .replace("Derivative[2][a4][x4]", "ad2"))
    for b4_text, value in (("Derivative[2][b4][x4]", "0"),
                           ("Derivative[1][b4][x4]", "0"), ("b4[x4]", "1")):
        text = text.replace(b4_text, value)  # the record at b4 = 1
    rust = sp.sympify(text.replace("^", "**"), locals={"H": H, "ad1": ad1, "ad2": ad2})
    reproduces(sp.expand(rust - Lscalar[k]) == 0,
               f"L_({k}) equals the Rust GKD program", PY, f"L{k}_equals_gkd_branch")
```

The Rust record stores each scalar as a text in the Wolfram Language; `.replace` turns the Wolfram name of the derivative into `ad1` and the power sign `^` into `**`, and `sp.sympify` turns the text into a sympy expression (`locals` says which names are our symbols). The scalars must agree. Out [16] shows the ten PASS lines.

In [17], all 192 components compared with the Rust and Wolfram records.

```
symbols_of_monomial = (H, ad1, ad2, ad3, sp.Symbol("ad4"), sp.Symbol("Ee"),
                       sp.Symbol("Ss"), cz)  # the order of the exponents

def from_monomials(monomials):
    total = sp.Integer(0)
    for numerator, denominator, exponents in monomials:
        if any(exponents[9:13]):  # a derivative of b4: zero at b4 = 1
            continue
        term = sp.Rational(numerator, denominator)  # b4^(1/2) = 1 (exponent 8)
        for symbol, power in zip(symbols_of_monomial, exponents[:8]):
            term *= symbol ** power
        total += term
    return total
```

The Rust program stores each component as a list of **monomials**: a fraction (numerator, denominator) and the eight exponents of H, a_4', a_4'', a_4''', a_4'''', e^{a_4}, $\sin^{1/3} z$ and $\cot z$, in this order. `from_monomials` rebuilds the expression: each term is the fraction times every symbol to its power (`*=` multiplies a variable), and the terms are added.

```
for k in (1, 2, 3):
    block = lovelock_json[f"P{k}_mixed_up_h_down_j"]
    same = all(sp.expand(from_monomials(block[f"{NAMES[h]},{NAMES[j]}"]["monomials"])
                         - P[k][h][j]) == 0 for h in range(N) for j in range(N))
    reproduces(same, f"all 64 components of P_({k}) equal the Rust GKD record",
               PY, f"P{k}_equals_gkd_branch_monomials")
```

For each k the record's block is a dictionary keyed by `"x1,x1"` and so on; every one of the 64 rebuilt components must equal the notebook's. A component of the record that contained e^{a_4}, the warp or a third derivative would differ, so the check also confirms that none does.

```
equations_json = read_json(EQUATIONS)
LOCALS = {"ad1": ad1, "ad2": ad2, "H": H}

def parse(text, names=None):
    return sp.sympify(text.replace("^", "**"), locals=names or LOCALS)
```

The Wolfram record is read; `parse` turns one of its texts into a sympy expression (`names or LOCALS` uses the dictionary `names` when one is given and `LOCALS` otherwise; docstring left out).

```
POSITIONS = {"x1x1": (1, 1), "x4x4": (4, 4), "x5x5": (5, 5), "x0x0": (0, 0),
             "x4x0": (4, 0), "x0x4": (0, 4)}
same = all(sp.expand(parse(equations_json["lovelockTensors"][f"E{k}"][key]["input"])
                     - E[k][h][j]) == 0
           for k in (1, 2, 3) for key, (h, j) in POSITIONS.items())
reproduces(same, "E_(1), E_(2), E_(3) equal the Wolfram record a4-equations.json",
           PY, "json_lovelock_components")
```

The record stores six components of each tensor (the four distinct diagonal ones and the two mixed ones x_4x_0, x_0x_4), each with an `"input"` text. All 18 must equal the notebook's.

In [18], an independent route to the Gauss-Bonnet tensor.

```
def contract(mu, nu):
    term_a = ricci_scalar * Ricci[mu][nu]
    term_b = sum(Ricci[mu][a] * Ricci[a][nu] for a in range(N))
    term_c = sum(R.get((mu, a, nu, b), 0) * Ricci[b][a]
                 for a in range(N) for b in range(N))
    term_d = sum(R.get((mu, a, b, c), 0) * R.get((b, c, nu, a), 0)
                 for a in range(N) for b in range(N) for c in range(N))
    return 2 * (term_a - 2 * term_b - 2 * term_c + term_d)
```

The bracket of the Lanczos formula printed in the text cell before the cell, term by term: $R\,R^{\mu}{}_{\nu}$, $\sum_a R^{\mu}{}_a R^a{}_{\nu}$, $\sum_{a,b} R^{\mu a}{}_{\nu b} R^b{}_a$ and $\sum_{a,b,c} R^{\mu a}{}_{bc} R^{bc}{}_{\nu a}$, combined with the factors 2, -4, -4 and 2 (docstring left out).

```
gauss_bonnet_scalar = (ricci_scalar ** 2
                       - 4 * sum(Ricci[a][b] * Ricci[b][a]
                                 for a in range(N) for b in range(N))
                       + sum(v * R.get((m, n, a, b), 0)
                             for (a, b, m, n), v in R.items()))
lanczos = [[sp.expand(contract(mu, nu)
                      - (gauss_bonnet_scalar / 2 if mu == nu else 0))
            for nu in range(N)] for mu in range(N)]
check(all(sp.expand(lanczos[h][j] - E[2][h][j]) == 0
          for h in range(N) for j in range(N)),
      "E_(2) (GKD) equals the classical Gauss-Bonnet tensor for every a4")
```

The Gauss-Bonnet scalar $R^2 - 4R^a{}_b R^b{}_a + R^{ab}{}_{cd} R^{cd}{}_{ab}$ (the last sum multiplies each stored component by the one with the two pairs exchanged); the Lanczos tensor subtracts half of it on the diagonal. The check compares all 64 components with $E_{(2)}$ from the GKD: two entirely different routes give the same tensor for every a_4.

```
A = sp.symbols("A", real=True)  # the slope of the linear member, a4' = A H
LINEAR = {ad1: A * H, ad2: 0}
reproduces(sp.expand(lanczos[4][4].subs(LINEAR)
                     + H ** 4 * (36 * A ** 4 + 120 * A ** 2 + 420)) == 0,
           "linear member: Gauss-Bonnet H^x4_x4 = -H^4 (36 A^4 + 120 A^2 + 420)",
           LEAD, "gauss_bonnet_rho_alpha2")
reproduces(sp.expand(lanczos[1][1].subs(LINEAR)
                     - 12 * H ** 4 * (A ** 4 + 14 * A ** 2 - 15)) == 0,
           "linear member: Gauss-Bonnet H^x1_x1 = 12 H^4 (A^4 + 14 A^2 - 15)",
           LEAD, "gauss_bonnet_p_alpha2")
```

For the linear member ($a_4' = AH$, $a_4'' = 0$) the time and 3-space components are compared with the numbers of the lead's independent computation.

In [19], the Bianchi identity.

```
def divergence(T):
    return [clean(sum(d(T[m][n], m) for m in range(N))
                  + sum(Gamma[m][m][l] * T[l][n] for m in range(N) for l in range(N))
                  - sum(Gamma[l][m][n] * T[m][l] for m in range(N) for l in range(N)))
            for n in range(N)]
```

The covariant divergence of a mixed tensor, $\nabla_\mu T^\mu{}_\nu = \sum_\mu \partial_\mu T^\mu{}_\nu + \sum_{\mu,l} \Gamma^\mu{}_{\mu l} T^l{}_\nu - \sum_{\mu,l} \Gamma^l{}_{\mu\nu} T^\mu{}_l$, for each ν; the result is a list of eight cleaned expressions (docstring left out).

```
AS_FUNCTIONS = {ad2: sp.Derivative(a4, (x4, 2)), ad1: sp.Derivative(a4, x4)}
for k in (1, 2, 3):
    Ek_functions = [[E[k][h][j].subs(AS_FUNCTIONS) for j in range(N)]
                    for h in range(N)]
    reproduces(all(value == 0 for value in divergence(Ek_functions)),
               f"nabla_mu E_({k})^mu_nu = 0 for nu = x0..x7",
               PY, f"E{k}_divergence_free")
```

The symbols `ad1`, `ad2` are plain letters, which `sp.diff` would treat as constants; so they are written back as derivatives of the function $a_4(x_4)$ before the divergence is taken. For each k all eight components of the divergence must vanish: the Bianchi identity of Section 12.10.

In [20], figure 3: the three Lovelock tensors as heat maps.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.4))
for ax, k in zip(axes, (1, 2, 3)):
    values = np.array([[float(E[k][h][j].subs(SAMPLE)) for j in range(N)]
                       for h in range(N)])
    scale = np.abs(values).max()
    ax.imshow(values, cmap="RdBu_r", vmin=-scale, vmax=scale)
```

`plt.subplots(1, 3, ...)` makes one row of three axes. For each tensor the 64 components are evaluated at the sample point of In [10] into an 8 by 8 array and drawn with its own symmetric colour scale.

```
    for h in range(N):  # write each diagonal value into its cell
        value = values[h, h]
        text = f"{value:.0f}" if abs(value) >= 100 else f"{value:.1f}"
        ink = "white" if abs(value) > 0.6 * scale else "black"  # readable on dark
        ax.text(h, h, text, ha="center", va="center", fontsize=6.5, color=ink)
```

Each diagonal value is written into its cell: as a whole number (`:.0f`) when it is at least 100 and with one decimal (`:.1f`) otherwise, in white on dark cells and black on light ones; `ha` and `va` centre the text.

```
    ax.set_xticks(range(N))
    ax.set_xticklabels(NAMES, fontsize=7)
    ax.set_yticks(range(N))
    ax.set_yticklabels(NAMES, fontsize=7)
    ax.grid(False)
```

```
    ax.set_title(f"$E_{{({k})}}{{}}^h{{}}_j$")
fig.suptitle("The three Lovelock tensors at $H=1$, $a_4'=0.6$, $a_4''=0.3$ "
             "(row $h$, column $j$)")
save_figure(fig, "lovelock_heat_maps",
            ...)
```

Ticks labelled x_0 to x_7, no grid, a title per panel (in an f-string a doubled brace prints one brace, so the title is the mathematics ${E_{(k)}}^h{}_j$), a title for the whole figure, and `save_figure`. **What the figure shows.** All three tensors are diagonal with only four different values, one each for 3-space, the time, the extra times and the hidden direction: the structure that reduces the 64 field equations to four.

In [21], the field equations.

```
alpha1, alpha2, alpha3 = sp.symbols("alpha1 alpha2 alpha3", real=True)
Lam, kappa = sp.symbols("Lam kappa", real=True)  # Lambda and kappa
rho, p3, pt, p0, q40, q04 = sp.symbols("rho p3 pt p0 q40 q04", real=True)
ALPHA = {1: alpha1, 2: alpha2, 3: alpha3}
```

Symbols for the couplings, Λ (named `Lam`, because `lambda` is a word of Python), κ and the six parts of the source; `ALPHA` finds the coupling of each k.

```
LHS = [[sp.expand(sum(ALPHA[k] * E[k][h][j] for k in (1, 2, 3))
                  + (Lam if h == j else 0)) for j in range(N)] for h in range(N)]
T = [[sp.Integer(0)] * N for _ in range(N)]
for i, value in enumerate([p0, p3, p3, p3, -rho, pt, pt, pt]):
    T[i][i] = value  # the diagonal of the source, in the order x0..x7
T[4][0], T[0][4] = q40, q04  # the two mixed components x4-x0 and x0-x4
```

`LHS` is the left-hand side $\sum_k \alpha_k {E_{(k)}}^h{}_j + \Lambda\delta^h_j$ of Section 12.8. `T` is the source: zeros, then the diagonal from the list, then the two mixed components (two variables can be set in one line).

```
off_diagonal_zero = all(LHS[h][j] == 0 for h in range(N) for j in range(N)
                        if h != j)
groups_equal = (LHS[1][1] == LHS[2][2] == LHS[3][3]
                and LHS[5][5] == LHS[6][6] == LHS[7][7])
reproduces(off_diagonal_zero and groups_equal,
           "every off-diagonal left-hand side is 0; four independent components",
           WL, "independent_components")
```

The two facts of the reduction: every off-diagonal left-hand side is zero, and the left-hand sides are equal within the two groups.

```
e11, e44, e55, e00 = (sp.expand(LHS[i][i] - Lam) for i in (1, 4, 5, 0))
say(f"constraint (x4): {e44} + Lam = -kappa*rho")
say(f"hidden (x0): {e00} + Lam = kappa*p0")
```

The four abbreviations $e_{11}, e_{44}, e_{55}, e_{00}$ (the diagonal without Λ; a parenthesised generator expression yields the four values, which are unpacked into four names). The constraint and the hidden equation

are printed for all three couplings; set $\alpha_2 = \alpha_3 = 0$, $\alpha_1 = 1$ in Out [21] and you read off $3(a_4')^2 + 21H^2$ and $15H^2 - 3(a_4')^2$.

In [22], the evolution equation.

```
F = sp.expand(sp.cancel((e11 - e55) / ad2))  # (e11 - e55)/a4''
report("F(a4')", F)
reproduces(not F.has(ad2) and sp.expand(ad2 * F - (e11 - e55)) == 0,
           "evolution: e11 - e55 = a4'' F(a4') = kappa (p3 - pt)",
           PY, "evolution_factorises")
```

$(e_{11} - e_{55})/a_4''$ is simplified by `sp.cancel`; the result F contains no a_4'', and $a_4'' F$ gives back $e_{11} - e_{55}$ exactly. Out [22] prints F, the polynomial of Section 12.9.

```
coefficients = sp.Poly(F, ad1, H).coeffs()  # every coefficient must vanish
solutions = sp.solve(coefficients, [alpha1, alpha2, alpha3], dict=True)
reproduces(solutions == [{alpha1: 0, alpha2: 0, alpha3: 0}],
           "F vanishes identically only for alpha1 = alpha2 = alpha3 = 0",
           PY, "evolution_F_not_identically_zero")
```

Read as a polynomial in a_4' and H, F has coefficients that depend on the couplings (`.coeffs()` lists them). F is zero for every a_4' and H only if every coefficient is zero; `sp.solve` solves these equations for the couplings and finds only $\alpha_1 = \alpha_2 = \alpha_3 = 0$.

```
reproduces(sp.expand(e11 + e55 - 2 * e00) == 0,
           "e11 + e55 = 2 e00 identically: the source needs p3 + pt = 2 p0",
           PY, "algebraic_identity")
reproduces(not e44.has(ad2) and not e00.has(ad2),
           "the x4 (constraint) and x0 components contain a4' but not a4''",
           PY, "constraint_and_x0_first_order")
```

The algebraic identity of Section 12.9, and the first-order character of the constraint and of the hidden equation.

In [23], constraint propagation and the record's equations.

```
reproduces(sp.expand(sp.diff(e44, ad1) * ad2 - 3 * ad1 * (e11 - e55)) == 0,
           "d/dx4 e44 = 3 a4' (e11 - e55) (constraint propagation)",
           PY, "bianchi_x4")
```

e_{44} depends on x_4 only through a_4', so by the chain rule its derivative with respect to x_4 is $(\partial e_{44}/\partial a_4')\, a_4''$, written `sp.diff(e44, ad1) * ad2`. It must equal $3a_4'(e_{11} - e_{55})$: the identity of Section 12.10.

```
general = equations_json["generalSource"]
NAMES_RECORD = {"ad1": ad1, "ad2": ad2, "H": H, "alpha1": alpha1, "alpha2": alpha2,
                "alpha3": alpha3, "Lam": Lam, "kappa": kappa, "rho": rho, "p3": p3,
                "pt": pt, "p0": p0, "AA": A}
```

```
def parse_equation(text):
    left, right = text.split(" == ")
    return sp.expand(parse(left, NAMES_RECORD) - parse(right, NAMES_RECORD))
```

The record's general equations are read; `NAMES_RECORD` maps every name used in the record to our symbols (the record writes the slope as `AA`). `parse_equation` splits a text `left == right` at the equality sign and returns left minus right (docstring left out).

```
mine = {"constraint_x4": e44 + Lam + kappa * rho,
        "space_x1_eq_x2_eq_x3": e11 + Lam - kappa * p3,
        "extraTime_x5_eq_x6_eq_x7": e55 + Lam - kappa * pt,
        "hidden_x0": e00 + Lam - kappa * p0,
        "evolution_x1_minus_x5": ad2 * F - kappa * (p3 - pt),
        "algebraic_condition": p3 + pt - 2 * p0}
same = all(sp.expand(parse_equation(general[key]["input"]) - value) == 0
           for key, value in mine.items())
same = same and sp.expand(parse(general["evolution_F"]["input"], NAMES_RECORD)
                          - F) == 0
reproduces(same, "the six equations and F equal the record a4-equations.json",
           PY, "json_general_source_equations")
```

The notebook's own six equations, each written as left minus right under the record's key, are compared with the record's, and so is F.

In [24], figure 4: the factor F.

```
F_numeric = sp.lambdify((ad1, alpha1, alpha2, alpha3), F.subs(H, 1), "numpy")
u = np.linspace(-3.0, 3.0, 601)  # a4'/H
cases = [(1, 0.0, 0.0, "Einstein: $\\alpha_1=1$"),
         (1, 0.005, 0.0, "$\\alpha_2H^2=0.005$"),
         (1, 0.01, 0.0, "$\\alpha_2H^2=0.01$"),
         (1, 0.02, 0.0, "$\\alpha_2H^2=0.02$"),
         (1, 0.01, 0.0005, "$\\alpha_2H^2=0.01$, $\\alpha_3H^4=0.0005$")]
```

`sp.lambdify` turns the exact formula (with $H = 1$) into a fast numpy function of a_4' and the three couplings. `u` holds 601 values of a_4'/H. `cases` lists five sets of couplings with their legend labels.

```
fig, ax = plt.subplots()
for a1, a2, a3, label in cases:
    values = F_numeric(u, a1, a2, a3) * np.ones_like(u) / 2
    ax.plot(u, values, label=label)
for a2 in (0.005, 0.01, 0.02):  # the zeros of F for Gauss-Bonnet gravity
    root = np.sqrt((1 - 40 * a2) / (24 * a2))
    ax.plot([-root, root], [0, 0], "o", color="black", markersize=4)
ax.axhline(0.0, color="black", linewidth=0.8)
```

For each case $F/2$ is computed on the whole array and drawn. In Einstein gravity $F = 2$ does not depend on a_4', but the function still returns an array of 601 values, all equal to 2: the formula that

`sp.lambdify` turned into Python contains terms such as `720*ad1**4*alpha3`, and with `alpha3` equal to `0.0` such a term is the array `u**4` times zero. Multiplying by `np.ones_like(u)` (an array of ones of the same length) is therefore only a safeguard: a formula with no a_4' left in it (for example after a simplification) would make the function return the single number 2, and the factor would turn that into an array of the right length as well. The second loop marks the two zeros $\pm\sqrt{(1-40\alpha_2)/(24\alpha_2)}$ of each Gauss-Bonnet curve (Section 12.9) with black dots; `ax.axhli ne` draws the horizontal line $F = 0$.

```
ax.set_xlabel("$a_4'/H$")
ax.set_ylabel("$F(a_4')/2$")
ax.set_title("The factor $F$ of the evolution equation $a_4''F = \\kappa(p_3-p_t)$")
ax.legend(fontsize=8)
save_figure(fig, "evolution_factor",
            ...)
```

Labels, title, legend and `save_figure`. **What the figure shows.** In Einstein gravity $F/2 = 1$ everywhere. With a positive Gauss-Bonnet coupling F falls like a downward parabola and crosses zero at the black dots, sooner for larger α_2; beyond the dots the evolution equation changes sign, and at the dots it cannot be solved for a_4'' (Notebook 12c, section 12 of the notebook, integrates into such a point). The third-order coupling adds a positive $(a_4')^4$ term that lifts the curve again.

In [25], the conservation law of a general source.

```
source = {name: sp.Function(name)(x4, z)
          for name in ("rho", "p3", "pt", "p0", "q40", "q04")}  # f(x4, z)
Tgeneral = [[sp.Integer(0)] * N for _ in range(N)]
for i, name in enumerate(["p0", "p3", "p3", "p3", "rho", "pt", "pt", "pt"]):
    Tgeneral[i][i] = source[name]
Tgeneral[4][4] = -source["rho"]  # T^x4_x4 = -rho
Tgeneral[4][0], Tgeneral[0][4] = source["q40"], source["q04"]
divT = divergence(Tgeneral)
```

Now the six parts of the source are unknown functions of x_4 and z (so of x_0), made with `sp.Funct ion(name)(x4, z)`. The tensor is filled as in In [21] (the time entry is first set to ρ by the loop and then corrected to $-\rho$), and its divergence is computed with the function of In [19].

```
a4p = sp.Derivative(a4, x4)  # a4' as a derivative, for the comparison
expect_x4 = (-d(source["rho"], 4) - 3 * a4p * (source["p3"] - source["pt"])
             + d(source["q04"], 0) - 6 * H * sp.tan(z) * source["q04"])
expect_x0 = (d(source["p0"], 0) + d(source["q40"], 4)
             + 3 * H * sp.cot(z) * (2 * source["p0"] - source["p3"] - source["pt"]))
```

The two expected components of Section 12.10, written with the function `d` (so that $\partial_0 = 6H\,\partial_z$ is used consistently) and with a_4' as a derivative.

```
reproduces(clean(divT[4] - expect_x4) == 0, "nabla_mu T^mu_x4 as in the record",
           EMT, "divergence_x4_component")
reproduces(clean(divT[0] - expect_x0) == 0, "nabla_mu T^mu_x0 as in the record",
```

```
           EMT, "divergence_x0_component")
reproduces(all(divT[n] == 0 for n in (1, 2, 3, 5, 6, 7)),
           "nabla_mu T^mu_nu = 0 identically for the six other nu",
           PY, "conservation_components")
```

The x_4 and x_0 components equal the expected ones, and the six others vanish.

In [26], Einstein gravity: no vacuum and the null energy condition.

```
EINSTEIN = {alpha1: 1, alpha2: 0, alpha3: 0}
null_x0 = sp.expand((e00 - e44).subs(EINSTEIN))  # kappa (rho + p0)
report("Einstein: kappa (rho + p0)", null_x0)
reproduces(sp.expand(null_x0 + 6 * ad1 ** 2 + 6 * H ** 2) == 0,
           "Einstein: kappa (rho + p0) = -6 (a4'^2 + H^2) < 0",
           PY, "einstein_null_energy_x0")
```

From the constraint $\kappa\rho = -(e_{44} + \Lambda)$ and the hidden equation $\kappa p_0 = e_{00} + \Lambda$ follows $\kappa(\rho + p_0) = e_{00} - e_{44}$; with the Einstein couplings this is $-6H^2 - 6(a_4')^2$, the result of Section 12.11.

```
vacuum = [LHS[i][i].subs(EINSTEIN) for i in (1, 4, 5, 0)]  # T = 0
real_solutions = sp.solve(vacuum, [Lam, ad1, ad2], dict=True)  # ad1, ad2 real
say(f"real solutions of the vacuum equations: {real_solutions}")
```

With $T = 0$ the four left-hand sides must vanish. `sp.solve` looks for Λ, a_4', a_4''; because `ad1` and `ad2` were declared real, it returns only real solutions, and there are none (`[]`).

```
w1, w2 = sp.symbols("w1 w2")  # a4' and a4'' again, now allowed to be complex
as_complex = [value.subs({ad1: w1, ad2: w2}) for value in vacuum]
complex_solutions = sorted(sp.solve(as_complex, [Lam, w1, w2], dict=True), key=str)
say(f"solutions when a4' = w1 and a4'' = w2 may be complex: {complex_solutions}")
imaginary = all(not solution[w1].is_real for solution in complex_solutions)
reproduces(real_solutions == [] and len(complex_solutions) == 2 and imaginary,
           "Einstein: no real vacuum solution for H > 0 and any Lambda",
           LEAD, "no_vacuum_for_H_positive")
```

To see what the equations would want, a_4' and a_4'' are replaced by symbols without the property real. Now sympy finds exactly two solutions, $\Lambda = -18H^2$, $a_4' = \pm iH$, $a_4'' = 0$ (sorted by their printed text, so that the order is the same in every run). Both slopes are imaginary (`.is_real` is false), as derived in Section 12.11.

```
einstein_record = equations_json["einstein"]
mine_einstein = {"constraint_x4": e44.subs(EINSTEIN) + Lam + kappa * rho,
                 "hidden_x0": e00.subs(EINSTEIN) + Lam - kappa * p0,
                 "evolution": 2 * ad2 - kappa * (p3 - pt)}
same = all(sp.expand(parse_equation(einstein_record[key]["input"]) - value) == 0
           for key, value in mine_einstein.items())
reproduces(same, "the Einstein equations equal the record", PY, "json_einstein")
```

The Einstein constraint, hidden equation and evolution equation are compared with the record's.

In [27], figure 5: why there is no vacuum.

```
u = np.linspace(-3.0, 3.0, 301)  # a4'/H
lam_constraint = -(3 * u ** 2 + 21)  # Lambda/H^2 that the x4 equation needs
lam_hidden = 3 * u ** 2 - 15  # Lambda/H^2 that the x0 equation needs
fig, ax = plt.subplots()
ax.plot(u, lam_constraint, label="$\\Lambda$ needed by the constraint ($x_4$)")
ax.plot(u, lam_hidden, label="$\\Lambda$ needed by the hidden equation ($x_0$)")
ax.fill_between(u, lam_constraint, lam_hidden, color="grey", alpha=0.25,
                label="gap $6(a_4')^2+6H^2=-\\kappa(\\rho+p_0)$")
```

With $\rho = 0$ the constraint needs $\Lambda = -(3(a_4')^2 + 21H^2)$, and with $p_0 = 0$ the hidden equation needs $\Lambda = 3(a_4')^2 - 15H^2$. Both are drawn against a_4'/H; `ax.fill_between` shades the region between them in grey (25 per cent opaque).

```
ax.set_xlabel("$a_4'/H$")
ax.set_ylabel("$\\Lambda/H^2$")
ax.set_title("Einstein gravity: the vacuum equations have no common solution")
ax.legend(fontsize=8, loc="upper center")  # the empty area above the curves
save_figure(fig, "no_vacuum_gap",
            ...)
```

Labels, title, the legend placed in the empty upper middle, and `save_figure`. **What the figure shows.** The two curves never meet: the lower one is never above $-21H^2$, the upper one never below $-15H^2$. Their vertical distance, $6(a_4')^2 + 6H^2$, is at its smallest, $6H^2$, at $a_4' = 0$; it is exactly $-\kappa(\rho + p_0)$, the violation of the null energy condition.

In [28], the linear member.

```
reproduces(sp.expand((e11 - e00).subs(LINEAR)) == 0
           and sp.expand((e55 - e00).subs(LINEAR)) == 0,
           "linear member: p3 = pt = p0 = p (any alpha_k)",
           PY, "linear_member_equal_pressures")
```

With $a_4' = AH$, $a_4'' = 0$ (the dictionary `LINEAR` of In [18]) the 3-space, extra-time and hidden left-hand sides are equal, so the three pressures are equal, for every coupling.

```
rho_linear = sp.expand(-(e44 + Lam).subs(LINEAR) / kappa)  # from the constraint
p_linear = sp.expand((e00 + Lam).subs(LINEAR) / kappa)  # from the hidden equation
say(f"kappa rho = {sp.expand(kappa * rho_linear)}")
say(f"kappa p = {sp.expand(kappa * p_linear)}")
```

The required ρ and p follow from the constraint and the hidden equation; $\kappa\rho$ and κp are printed: the general formulas of Section 12.12.

```
